Acerca de este libro

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

Normas de uso

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

+ *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.
+ *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.
+ *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.
+ *Manténgase siempre dentro de la legalidad* Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

Acerca de la Búsqueda de libros de Google

El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página `http://books.google.com`

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

SUPPLEMENT TO "THE ELECTRICAL ENGINEER," DEC. 25, 1896.

THE ELECTRICAL ENGINEER.

A WEEKLY JOURNAL OF ELECTRICAL ENGINEERING,

WITH WHICH IS INCORPORATED

"ELECTRIC LIGHT."

VOL. XVIII. (NEW SERIES.)

FROM JULY 3, 1896, TO DECEMBER 25, 1896.

LONDON:
Printed and Published for the Proprietor by BIGGS & Co., at "THE ELECTRICAL ENGINEER" Offices, 139-140, Salisbury-court, Fleet-street, E.C.

1896.

Digitized by Google

INDEX TO VOL. XVIII. (New Series.)

NOTE.—General Articles, Correspondence, and Companies' Meetings are indicated by heavier type (thus, 290) than the Notes and Business Notes, references to which are shown by light type (thus, 290).

A.

Aarau Power House, The, 566
Aberdeen Harbour Electric Lighting Scheme, 301, 670
Accidents, Various, 1, 57, 87, 114, 153, 169, 191, 253, 309, 337, 365, 393, 395, 433, 443, 449, 452, 470, 505, 506, 539, 561, 565, 642, 647, 651, 652, 677, 678, 721

Accumulators:
Carbon-Consuming, 32
at Chester Electricity Works, 688
Chloride, The, 601
Clydebank, The, 479, 621
Jacques, The, 197, 569
Making of, in Spain, 706
at Manchester Corporation Electric Light Works, 601, 715
Parson's Improved Leclanche Zincs for, 237
Schmidt, The, 310
Sicarde and Falle, 705
Sola-Headland, The, 562
for Telegraphic Work, 4
"Thermo-tropic," 569

Accumulator Traction, Developments in, F. Ross, 62
Acetylene, 30, 337, 452, 533, 621, 669, 678
Action of Metals and their Salts on the Ordinary and Rontgen Rays: A Contrast, J. H. Gladstone and W. Hibbert, 440
Addresses, Change, etc., of, 24, 79, 137, 165, 195, 220, 247, 277, 303, 331, 388, 389, 416, 470, 559, 587, 671
Aerial Navigation (Air Ship), 451
Agency, Change of, 701
Agriculture, Electricity in, 5, 83, 450, 652, 721
Alden, C. A., Correct Position of a Trolley Wire over Curves, 97
Allen, A. H., The Conversion of Thermometer Readings, 46
Alloys, Aluminium, 1, 29
Alloys, Iron-Antimony, 3
Alloys, Resistance of, 4
Alternate-Current Motors (Leading Article), 14
Alternate-Current Motor Tests, Prof. Jackson, 143, 244
Alternate-Current Motor Tests, Prof. Thompson, 20
Alternate-Current Transformers, Dr. Fleming, 72, 101, 129, 158, 179, 213
Alternate-Current Wave Forms, The Recording of, F. Drexler, 36
Alternate-Current Working, Principles of, A. Hay, 10, 65, 90, 184, 206, 232, 268, 287, 342, 374, 426, 454, 482, 542, 570, 599, 654
Alternators, *see* DYNAMOS, ETC.
Alumina Factory at Larne Harbour, J. Sutherland, 185
Aluminium Alloys, 1, 29
Aluminium, Corrosion of, 421
Aluminium, Is it Poisonous? 226
Aluminium Production at Foyers, 277
Aluminium in Shipbuilding, 428
American Institute of Electrical Engineers, 253
American on Labour, An, 288
American Patents, Growth of, 170
American Publications for Europe, 593
American View, An (Electrical Progress), 255
Amsterdam, Electrically Operated Locks at, 499
Andrews Return Current Cut-Out and Synchronising Switch, 407
Annual Meeting, The (Leading Article), 691
Antimony-Iron Alloys, 3
Antitoxins and Electrolysis, 490
Apostoloff Automatic Telephone, 183
Applied Electro-Chemistry, J. Swinburne, 324, 355, 375, 410, 440, 466, 495, 556
Appointments, 5, 30, 115, 137, 273, 277, 279, 309, 388, 416, 614
Appointments Vacant, 25, 54, 83, 109, 139, 166, 192, 220, 248, 278, 304, 333, 361, 416, 471, 499, 534, 560, 588, 615, 643, 670, 674
Archbishop Tenison's School, Alterations at, 523
Arc in Gases, The, 624

Arc Lamps:
Brockie-Pell, The, 139
Carbons, Some Faults in, W. M. Stine, 157
with Enclosed Arcs, 197
Jandus, The, 24, 192, 388, 586
Koerting and Mathiesen, The, 115
Poor, H. L. Rogers, 116
Vanbe, The, 236

Arc Lighting, Cost of, 282
Arc Lighting, a New System of Series, T. Spencer, 604
Arc in a Magnetic Field, J. B. Hall, 60
Arc, Physics of, 2
Are Central Stations Doomed (Leading Article), 663
Argon, 199, 225
Armature Torque, T. Wolcott, 148
Asbestos, Discovery of "Mountain" of, 506
As Others See Us (Leading Article), 634
Asquith, Mr., Address at Yorkshire College, 480
Assistance to British Trade Abroad, 226
Association of Municipal and County Engineers, 16, 370
Association of Yorkshire Students of Civil Engineers, 596
Associated Chambers of Commerce, 169
Asynchronous Motors, M. Goerges on, 621
Automatic Electric Lift, 227
Awards, 1, 45, 59, 113, 141, 253, 281, 531, 624

B.

Bad Light and School Children, 449
Baker, J. A., Letter to Highways Committee of London County Council on Tramways, 527
Baker, Sir B., Report on Underground Electric Express, 549
Balfour, Mr. J. A., on Technical Education, 597

THE

ELECTRICAL ENGINEER.

No. 1, Vol. XVIII. LONDON, JULY 3, 1896. PRICE 3D.

NOTES.

Elektrotechnischer Verein.—The *Zeitschrift für Elektrotechnik* for June opens with an obituary note in reference to the recent death of the Archduke Charles Louis of Austria, who was patron of the Vienna Electrical Engineering Society.

South Kensington Museum.—The Lords of the Committee of Council on Education have appointed Mr. C. Purdon Clarke, C.I.E., F.S.A., director of the South Kensington Museum in succession to the late Dr. Middleton. Mr. A. B. Skinner, B.A., succeeds Mr. Purdon Clarke as assistant director.

A Breakdown.—According to the local Press, there was a temporary breakdown at the Cardiff generating station on Saturday last, so that "the principal streets of the town were suddenly plunged into semi-darkness. The accident occurred about 10 o'clock, and it took 20 minutes to remedy the defect." Evidently not a very serious affair.

Lundy Island Cable.—The cable to Lundy Island, which has not been working for about a fortnight, was repaired on Tuesday last and communication re-established. The fault was about three miles out from Croyde, and it is stated that some trouble was experienced in remedying the defect, owing to the heavy sea and high wind in the channel.

New Technical Paper.—We have received from Milan the first number of *L'Illuminazione*, a new monthly which is to be devoted to matters connected with lighting, whether by electricity, gas on the ordinary or the incandescent system, or oil. In the present number a large amount of space is devoted to the subject of acetylene. The paper is issued from Via Dante, 6, Milan.

Dublin Tramways.—We announced last week that the electric tramway had been purchased by the Dublin United Tramway Company. On the 28th ult. they managed somehow to break the overhead line at Kingstown, but nothing more serious happened than the temporary stoppage of the traffic until matters could be rearranged so as to run the traffic past the point of failure on a single line.

Wave-Forms.—It may be worth notice that Messrs. Beeton, Taylor, and Barr's paper at the Institution of Electrical Engineers on the influence of the shape of the applied potential difference wave on the iron losses of transformers is being reprinted in full in the New York *Electrical World*. In view of some remarks made on the discussion which followed that paper, any editorial or other opinions on the subject from American sources will be awaited with interest.

Finding a Bullet.—A Reuter's telegram from Berlin states that on a visit being paid by Li Hung Chang to the Charlottenburg Polytechnic the Chinese envoy, after being shown a number of experiments with the Röntgen rays, consented to an attempt being made to discover the position of the bullet fired at his head by the assassin at Shimonseki last year. The attempt was successful, and the image of the head which was obtained showed the track of the bullet in the left cheek, and the bullet itself lodged in the tissues slightly below the left eye.

An American Accident.—The *Western Electrician* describes an accident in which a linesman was killed owing to touching a loose wire which had been attached to a high-tension alternating overhead wire by a party of boys. While trying to cut the wire which was causing a leak of current, the linesman received a shock which killed him instantly. It is specially stated that the wire was "attached" in the daytime, so that it is probable that there was no day load, otherwise it would not be very clear how the boys escaped while the linesman was killed.

Rontgen Ray Tube.—In the *Elektrotechnische Zeitschrift* there is figured and described a form of Röntgen ray generating tube, evidently designed to secure as far as possible an effect which shall be as nearly as may be equivalent to a point origin for the radiations. There are two concave cathodes of relatively large size placed opposite to each other, and midway between them is the anode, which is V-shaped, and receives the focussed cathode rays at and near to its angle. A similar arrangement has been described by Mr. Elihu Thomson in America. It will be seen that the whole thing is practically a duplication of the concave cathode and slanting anode used by English workers almost from the beginning.

Aluminium Alloys.—According to Mr. Charles Margot, of Geneva, 72 parts of platinum and 28 of aluminium give an alloy having a golden yellow colour, whilst other tints can be obtained by varying the proportions of the two constituents, but the alloys are liable to be unstable, breaking up spontaneously. The yellow alloy is stable, but is brittle. An aluminium alloy containing 75 to 80 per cent. of cobalt has a colour ranging from straw to brown, is extremely hard, and will scratch glass, but is very brittle. Seventy-two per cent. of palladium with 28 per cent. of aluminium gives an alloy which is remarkable as having a copper-red colour; it is hard and brittle. With 82 parts of nickel to 18 of aluminium a straw colour alloy is produced, which is as hard as tempered steel, and can resist a hammer blow. *Aluminium* says this takes a fine polish, and has a fracture resembling that of bell-metal.

Nowotny Lamp.—In the *Western Electrician* there is a description of an arc lamp brought out by the Nowotny Electric Company of Chicago. It is a hanging lamp, in which the two carbons are not placed end to end, but parallel to each other, and have flat sides. The arc is kept at the end of the carbons by a magnetic field. The carbons are inside a glass globe, which "protects them from the access of fresh air" and prolongs their life. As this lamp is described as of an entirely new type, it may be as well to remark that many years ago, in the early days of electric lighting, a similar arrangement of carbons was tried, but the other way up, the result of the difference of position being that the arc stayed in its place at the top of the

Digitized by Google

carbons by itself, and there was no need to provide a magnetising coil to keep it there. Perhaps some day someone will reinvent the Jablochkoff candle and bring that out as an entirely new type of lamp.

Drills Superseded.—The New York *Electrical Review* is responsible for the following tale illustrating the way they do things in the States: A novel way of perforating iron plates is reported from Salt Lake City, says a daily paper. The city is being supplied with electricity for lighting and power, generated 14 miles away in the Big Cottonwood Canon. It was found necessary for the purpose of pipe connections to cut four 48in. openings in the 7ft. penstock, the plates of which were ½in. thick. The workmen began to cut with cape chisels, but the progress made was too exasperatingly slow for the engineer of the works, R. M. Jones, who is known throughout the West as the "cowboy engineer." Mr. Jones took up his rifle, and, using steel bullets cased with copper, shot a line of holes through the plates from a distance of about 30ft. The intervening edges were afterwards easily cut out, and in a very short time the job was finished.

The Telephone Service.—The *Financial Times* has opened its columns to complaints in reference to the telephone service in London. One correspondent imputes "incompetence and crass stupidity—not to say the deliberate defiance"—to the telephone employés. Another says: "When I had it (the telephone) in my office it caused me so much vexation and annoyance that I had to get rid of it to save my nerves from utter destruction. Now I am entirely dependent upon telegrams and messenger boys, and these are not nearly so efficient as the telephone ought to be." A third says: "I think you are very unfair to the National Telephone Company. I have always found the officials models of courtesy and long-suffering. For a long time past I have bothered them every few days with complaints that my telephone is out of order, and I invariably receive a courteous letter in reply, promising that the matter will be seen to. I am bound to say that they are one and all past masters in the art of apologising." But all the letters are anonymous.

The Seguy Ozoniser.—Mr. Gaston Seguy has presented to the Paris Académie des Sciences a note on his new tubular ozonising apparatus. From an illustration reproduced in *L'Electricien* the apparatus appears to be a very compact one. The arrangement is, so to speak, in three storeys, but the dimensions are unfortunately not given. At the bottom is a dynamo, above this three induction coils with make-and-breaks, and on the top stage the three ozonising tubes. Each of these contains seven interior tubes—of course, of smaller diameter—and open at the ends, and the discharge passes from aluminium spirals placed between these inner tubes. The air or oxygen operated on passes through all three of the big tubes in succession. With an E.M.F. of six volts and a primary current of eight amperes, the apparatus produces about 170 milligrammes of ozone per hour. Operating on oxygen as much as 250 milligrammes per hour can be obtained, the proportion being 56 milligrammes per litre of oxygen. With a slower passage of the gas, this proportion rises to 62 milligrammes.

The Physics of the Arc.—The discussion on the "negative resistance" of the arc has taken place at the Physical Society, and matters do not seem much forwarder. To the ordinary man a negative resistance seems very like a contradiction in terms, which can only lead to impossible results. But that is avoided by previously defining what is meant by the "resistance." Of course, any definition which accurately represents the phenomena will do as a basis for mathematical treatment, but the difficulty is that when the same name is used for both it is almost impossible to avoid mixing up the ideas proper enough to a physical conception with those belonging to what is a purely mathematical rendering of observed results. Considering the complicated nature of the phenomena to be dealt with, the argument that from the temperature of the arc being greater than that of the crater, though certainly a presumption against the former containing an energy-giving region, is not absolutely conclusive. Of the facts there should be no manner of doubt; the question is whether the new way of conceiving them is a helpful one. At present the matter seems, as Prof. Rücker said, to be in considerable confusion.

Cable Interruptions.—From the official list of interruptions given in the Berne *Journal Télégraphique* of June 25, it appears that the Ceara-Maraham failure of April 28 was repaired on June 19. The Amazon Company's line beyond Monte Alegre was not reported to be working at the time the list was compiled. Next come two interruptions of Columbian (New Grenada) land lines now repaired and a breakage of communication with Bissao and Bolama, which is not yet repaired. The Cadiz and Teneriffe cable, which failed on June 6, and the Jamaica and Colon (Aspinwall) failure of June 10 are reported as not yet repaired, while a 10-day interruption of the Saigon and Bangkok line was repaired on June 25, apparently just in time for inclusion in the list. There was a two days' interruption of the Gibraltar and Tangiers cable on June 16, and the re-establishment of communications between Gwelo and Beira is of course dependent on circumstances outside the control of any moderate number of telegraphic engineers, even if the latter happen to find magazine rifles included in their outfit. Except two interruptions of Siberian land lines, the rest are either short interruptions repaired within the day or else failures of considerable antiquity.

Electric Fire-Engine.—An electrically-driven fire-engine has been brought out by Mr. Charles Brézol, of Charleville. It consists essentially of a force pump of the usual type driven by a two-pole motor, geared down to give the necessary speed reduction. There are suction and delivery hoses, and the whole is mounted on a two-wheel carriage or barrow with handles, so that one man only is necessary to bring it to the scene of action. *L'Energie Electrique* begins an illustrated description of this apparatus as follows: "Now that the smallest towns in France have a supply and distribution of electricity, and in most cases on a system of overhead wires, what could be more simple than to make use of the electric energy for working fire-engines"; and concludes by drawing the attention of all municipal authorities who have at their disposal a supply of current to this apparatus. Every little town, in this country at least, has not a system of electricity supply by accessible overhead wires, and is not likely to have at present, so that it is to be feared that Mr. Brézol's apparatus will not come into extensive employment. Our contemporary, however, suggests that it might also come in useful for watering public parks. A water supply under pressure would be handier

Electric Lighthouses.—Anything that Mr. Henry MacIver says must command a certain amount of attention in shipping circles, and it is therefore worth notice that he has written to the *Times* a letter showing that he is more than half inclined to believe that—as he cautiously puts it—"there is just a possibility that the disaster (the loss of the 'Drummond Castle') might not have occurred had Ushant been lighted by oil instead of electricity." Mr. MacIver adds: "I am afraid many sailors do not yet appreciate how little penetrating power an electric light

Digitized by Google

has in foggy weather." Quite so, but the inference that oil would be better does not immediately follow. Granted that under certain conditions so many candle-power of yellow (oil) light will penetrate a little further than the same number of candles of white (arc) light—neither will go very far in a fog—it is difficult to see how, so long as it contains the proper quantity of yellow light, the fact of the more powerful arc light having also a certain proportion of blue light in addition, which the fog would stop, is to prevent its yellow constituents penetrating. It is not wise to trust to picking up any light in hazy weather, but an argument based on the possibility of that principle not being acted on leads to the absurd result that a bad light is better than a good one.

Iron-Antimony Alloys.—According to a communication made to the Societé française de Physique, Mr. Pierre Weiss has been making experiments on the magnetic properties of alloys of antimony and iron. Mr. Weiss finds that these hold a position between the large class of feebly paramagnetic bodies and the group of iron, nickel, and iron combinations, which have strong magnetic properties. Using a ballistic galvanometer, Mr. Weiss plotted curves for antimony alloys containing from 26 to 56 per cent. of iron. The first of these showed hardly any magnetism, but there is sudden increase in the permeability on passing from samples containing 38 to 42 per cent. This is considered to point to the formation of a compound corresponding to the formula Fe_4Sb_3. Hysteresis diagrams were made with a view of comparison with the Steinmetz formula, which makes the energy dissipated by hysteresis in the course of one cycle equal to some power (not integral) of the maximum magnetisation multiplied by a coefficient which differs for different materials. The value of the exponent as hitherto determined has been 1·6, except in the case of very weak fields. Such iron-antimony alloys as were examined agreed very well with an exponential law, but for an alloy of 53 per cent. of iron the exponent was about 2·17, this figure falling gradually to the standard value of 1·6 as the proportion of iron is increased.

Electric Motorcarts.—Mr. W. Baxter, jun., has contributed an article to the New York *Engineering Magazine* on the subject of the "Horseless Carriage Problem." Mr. Baxter thinks that gas and oil engines having failed completely in competition with electricity for tramcar work will also fail in the same way with motorcarts. "What is true of street cars ought to be equally true of automobiles, as the only difference between them is that the former run on rails and the latter do not." Quite so, but unfortunately it is the trolley car that has prevailed, and clearly the economic performance of the trolley car is not evidence in the case of an accumulator car. Steam, Mr. Baxter considers to have failed completely for quite a quantity of reasons, which, put shortly, amount to the charges of being dangerous, troublesome, disagreeable, dirty, and unable to put on a spurt at starting. With gas and oil engines there are similar difficulties. Therefore nothing remains but the storage battery and electromotor. Again, Mr. Baxter thinks that motorcarts will not be used for pleasure purposes, but for the heavier work of parcels-delivery vans and wagons. Lastly, he looks for improvement in the storage battery. The great point made in favour of the electric motorcart is its ability to make a powerful effort for a short period. Now, this is just the point where, up to the present, animal traction has had the advantage of all kinds of machinery on ordinary roads.

Motorcarts.—The Locomotives on Highways Bill, which appears to be the official title of the measure for the legalisation of motorcarts, has begun its troubles in the Commons. On Tuesday, Mr. Chaplin moved the second reading and to refer the Bill to the Standing Committee on Law. Dr. Tanner opposed the Bill in the interests of sport, considering that "autocars" were "non-sporting machines." Mr. Daly (Monaghan) opposed it also because they breed horses in Ireland. The old fallacy as to broad wheels was brought forward by several members, and there were those who were anxious to tax an industry not yet in existence. Ultimately the Bill got into committee. It is stated that in Paris a committee of the Municipal Council is negotiating with the omnibus company with the object of substituting mechanical for horse power for trams and omnibuses. The Council thinks it desirable that, not only should the tramcars be drawn by mechanical power, but that the omnibuses should also be replaced by horseless vehicles. The Paris Municipal Council may very possibly be right more or less this time, but the opinions and desires of that body are not always accepted as immediately feasible. The first motorcar accident has been chronicled—also from Paris. The Comte de Dion's motor-brake, with nine people in it, got into complications between a farm cart on the wrong side of the way and a steam tramcar, with the result that being turned too sharply it capsized and pitched out its occupants.

Coventry Tramways.—A descriptive article on the subject of the Coventry electric tramways has appeared in the *Birmingham Daily Post.* Our Midland contemporary appears to prefer the system of two sets of poles, one on each side of the street, to one in the middle between the tramlines, but considers span wires much less objectionable than poles and brackets. The article is in no way technical in character, and after a good deal of graphic description of the effect of the wires, guide ropes, etc., seen against the sky, which "at one or two points suggest the rigging of a ship," it is added that "in Coventry the experience of the electric tramway is said to have won over even some of the strongest objectors to the introduction of the system. The cars, in spite of the ugly black jib projecting from the top, are regarded as a welcome change from the steam tram, the traffic is efficiently and expeditiously carried on, and the public are liberally treated." In conclusion, it is stated that "there is less sparking overhead than there is on the Walsall line; but the flashing and crackling underneath the car is sometimes rather alarming. One instance of a horse being startled by this is recorded, but the cars are constantly passing on each side of the cab-stand almost within arm's length, and the horses there take no notice." Evidently the writer of the article did not set out with a bias in favour of electric traction, but the opinions of the Coventry people on the subject seem to have impressed him.

Lamp Exhausting.—There was described some time ago in the *Zeitschrift für Beleuchtung* a method of exhausting incandescent lamps in which a chemical process is used in conjunction with the air pump. It is stated that most of the lamp factories in Germany are now using such chemical processes. In the tube attached to the lamp for exhausting it a piece of amorphous red phosphorus is introduced, the amount of which must be found empirically for each type of lamp. While it is being exhausted with the pump, this tube is heated carefully with a Bunsen burner; and when the vacuum is sufficient, the normal current is passed through the lamp and then increased gradually up to about three times the normal voltage, when a violet light will appear at the end of the filament. A few moments later a blue light will appear around the filament. The current should be reversed frequently, and after having run for 10 to 20 seconds at the high voltage the blue light will expand throughout the whole globe, and

Digitized by Google

at that moment the lamp must be sealed off so as to include the phosphorus. The lamp is then run again and heated at the tube which contains the phosphorus. A reaction will suddenly take place and the blue light will disappear, a scarcely visible light-brown deposit being formed on the glass, which it is said does not affect the candle-power. When a lamp exhausted in this way is tested with a Ruhmkorff coil, neither phosphorescence nor a current will be found to exist. The whole operation requires only 1·5 to 2 minutes with an experienced workman.

Accumulators for Telegraphic Work.—On the subject of the use of storage batteries in telegraphic offices the New York *Electrical World* remarks that in such work "storage batteries find an ideal field of application, and that their advantages are fully recognised by the telegraph officials is evident from the fact that their use in telegraph work is increasing rapidly." According to Mr. Maurice Barnett in an article on the subject, 3,116 storage cells of different capacities are now doing work which formerly required 20,407 primary (gravity) cells to perform. The original cost of the batteries is given as £2,000, and that of the storage cells about £1,700. After adding to the latter figures the cost of the auxiliary apparatus necessary for the operation of the storage battery plant, the difference is still in favour of the storage battery. The advantages and economies are still further increased by the large saving in space. "Output for output the primary battery requires four to six times more space than a storage battery, and space in most busy centres nowadays is easily resolved into its equivalent in dollars and cents. Another economy in favour of the storage battery plant is in the cost of maintenance. The primary battery, such as is used in telegraph work, is proverbially wasteful, yet its use has been tolerated because nothing better had been put forward to take its place until the advent of the motor dynamo and the improved storage cell. The latter, as manufactured to-day, is a device far more reliable in service than formerly, and it is quite as much due to the certainty that a given cell will supply a definite output as to the more weighty economies above referred to that the storage battery is finding so much favour in this particular branch of electrical industry."

Institution of Electrical Engineers.—The conversazione of the Institution of Electrical Engineers was given on Thursday, June 25, at the Royal Institution of Painters in Water-Colours, Piccadilly. There was a very large attendance indeed, the spacious rooms of the Painters in Water-Colours being at one portion of the evening quite crowded. Dr. Hopkinson and Mrs. Hopkinson received the numerous guests on their entrance. Among a large number of eminent persons present the following names may be mentioned: Sir Frederick Abel, Bart., K.C.B., F.R.S., Prof. W. Grylls Adams, F.R.S., Prof. Armstrong, F.R.S., Prof. W. E. Ayrton, F.R.S., Mr. Frank Bailey, Sir Benjamin Baker, K.C.M.G., Mr. A. E. Baylor (U.S.A.), Captain W. P. Brett, R.E., Mr. H. W. Christmas (Consul-General for Servia), Prof. Cleve, Captain E. W. Creak, R.N., F.R.S., Mr. R. E. Crompton, Prof. W. Crookes, F.R.S., Mr. W. B. Esson, Mr. S. Z. de Ferranti, Prof. G. Carey Foster, F.R.S., Mr. Charles Hawksley, Prof. D. E. Hughes, F.R.S., Mr. E. H. Johnson (U.S.A.), Lord Kelvin, D.C.L., F.R.S., Prof. A. B. W. Kennedy, F.R.S., Sir Henry Mance, C.I.E., Mr. Commerford Martin (U.S.A.), Mr. Kenric Murray, Major Cooper Penrose, R.E., Prof. John Perry, F.R.S., Mr. W. H. Preece, C.B., F.R.S., Prof. W. C. Roberts Austen, C.B., F.R.S., Major Ruck, R.E., Mr. Alexander Siemens, Mr. C. E. Spagnoletti, Mr. Augustus Stroh, Mr. J. W. Swan, F.R.S., Mr. J. Swinburne, Prof. S. P. Thompson, F.R.S., Sir E. Leader Williams, Mr. Edward Woods (past-president Institution of Civil Engineers), Major-General C. E. Webber, C.B. The Æolian Ladies' Orchestra played a selection of music, under the conductorship of Mr. R. Watson, and later on, when the crowd had thinned sufficiently to permit of it, a waltz or two wound up the evening.

Resistance of Alloys.—In reference to the suggestion of Lord Rayleigh's that part of the abnormal resistance of alloys might be due to a thermo-electric effect, it appears that some time ago Messrs. W. C. McMillan and R. H. Housman, of Mason College, Birmingham, endeavoured to determine the point experimentally. It is evident that if a reversal of current could be made so rapidly that the differences of temperature which are assumed by the hypothesis to be set up within the alloy would not have time to distribute themselves, the thermo-electric back E.M.F. could be eliminated. The method ultimately adopted was to balance the resistance of two pieces of wire, copper and alloy, and by means of a secohm-meter try if there appeared to be any diminution of the resistance of the alloy when the current was rapidly reversed. It is stated that indications which would support the correctness of the hypothesis were in this way obtained. It seems obviously impossible to get anything approaching quantitative results, since, the parts involved being so small, the redistribution of temperature must be exceedingly rapid. Moreover, apart from other disturbing effects, which would be difficult to eliminate, it does not appear easy to be certain that the alloy is absolutely homogeneous in character over measurable distances. It should be added that Messrs. McMillan and Housman's idea is that the effect is not a molecular one, but that one of the constituents of the alloy exists in the form of very minute "crystals" embedded either in the other or in a true mixture. If that were so, alloys which are chemical compounds would not give the effect; but that deduction is useless for practical purposes, since it is impossible to get such a chemical compound which does not contain some of either one or both of its constituents in an uncombined form as an "impurity."

Paraffin Lamps.—Sir Henry Roscoe and Prof. Dewar have been giving evidence before the House of Commons Committee on petroleum. Sir Henry Roscoe said there was no such thing known at present as a lamp which could be designated a safety lamp, and even if there were such a thing he did not see how its use could be insisted on by the Legislature. Therefore he had come to the conclusion that a change in the properties of the oils used must rather be looked to for an amelioration of the present state of things. The oils now in common use in this country, even with the ordinary precautions, were dangerous. After describing various experiments, Sir Henry Roscoe added that the general conclusions he had arrived at were, first of all, that the flash point was too low, and, second, that it was not possible to fix a practical flash point so high that all danger from fire could be avoided; but that if the flash point were raised to 100 or 105, a considerable diminution in the number of accidents from explosion and fire might be looked for. On the other hand, Prof. Dewar said from experiments he had made he had come to the conclusion that, if Parliament undertook legislation that would convey to the public that oil could be safely used in the present lamps, they would have to fix the flash point at 212deg. F., so that really it was impracticable to insure safety in the use of mineral oils by careless persons in the present lamps by simply raising the flash point. There was but little difference in the risk of accident from the use of oil of 100 flashing point and from

Digitized by Google

the use of oil of 73 flashing point in the lamps at present in use. From the reports of the chief officer of the fire brigade it appeared that in 1890 there were 271 lamp accidents and 473 in 1895.

Electricity in Agriculture.—The Chicago *Electrical Journal* contains a short account, apparently taken from another paper, of how a certain Mr. Israel Hogeland, of that city, has patented a device "which will allow a farmer to plough his field, harrow it, put in the seed, and, when the crop has grown, to harvest it by electricity." There is a feed-wire on all four sides of the field (this seems lavish; one should be enough), and "the farm machinery is provided with a trolley, which consists of a wire so arranged that it will wind or unwind on a cylinder on the back of the machine." The description is somewhat compressed—perhaps it is from this cause that that rather essential part the motor has got left out, but, for all we know to the contrary, the arrangement may be more practical than the description reads. However, quite apart from Mr. Hogeland's patent, there are those well able to judge who maintain that ultimately the immense "bonanza" farms worked by companies will supersede in many agricultural districts what the Americans consider "small" occupations of 300 acres or so. When that comes about it means steam cultivation, and it is obvious that an insulated wire carrying a current ought to be a more economical means of conveying energy to a plough or other agricultural machine than the wire rope now used in steam ploughing tackle. Recently some experiments have been made in this direction in Germany, and it is now stated that the German Government have taken the matter up, and are making trials with electrically-driven ploughs on the Sillium Estate in the Upper Hartz, but no figures as to the results are available, while the figures that are given as the results of similar experiments made by the Union Elektricitäts-Gesellschaft, which work out at nearly 15 h.p. to a ploughshare, are vitiated for purposes of comparison by the furrows being much broader and deeper than any that are ever drawn in this country.

The Society of Arts.—The Albert medal of the Society of Arts has been awarded, with the approval of the Prince of Wales, the president of the society, to Prof. David Edward Hughes, F.R.S., "in recognition of the services he has rendered to arts, manufactures, and commerce by his numerous inventions in electricity and magnetism, especially the printing telegraph and the microphone." Prof. Hughes is to be congratulated upon the receipt of a merited distinction. The council of the society have awarded silver medals to the following readers of papers during the session 1895-96: W. J. Dibdin, for his paper on "Standards of Light"; A. J. Hipkins, for his paper on "The Standard for Musical Pitch"; A. A. Campbell Swinton, for his paper on "Röntgen's Photography of the Invisible"; Dr. D. Morris, for his paper on "Bahamas Sisal Industry"; Edward W. Badger, for his paper on "Fruit and Vegetable Drying"; E. W. Moir, M.I.C.E., for his paper on "Tunnelling by Compressed Air"; Colonel R. G. Woodthorpe, C.B., R.E., for his paper on "The Shan Hills, their Peoples and Products"; J. H. Glass, for his paper on "The Great Landslip at Gohna, in Gurhwal, and the Measures adopted to Prevent Serious Loss of Life"; G. W. Christison, for his paper on "Tea-Planting in Darjeeling"; Frank Cundall, for his paper on "Jamaica in the Past and Present"; G. Scott Elliot, for his paper on "The Commercial Prospects of English East Africa and British Central Africa"; Charles R. Valentine, for his paper on "The Colonies and the Supply of Dairy Produce and the Products of Petite Culture"; Gleeson White, for his paper on "The Poster and its Artistic Possibilities"; William Burton, for his paper on "The Palette of the Potter"; and George Simonds, for his paper on "Bronze Casting in Europe." At the annual general meeting the following were the new vice-presidents elected to replace those retiring by seniority: Captain Abney, Sir G. Birdwood, Sir F. Bramwell, Viscount Cross, Mr. G. N. Curzon. The new members of council were Messrs. J. G. Gordon, H. G. Harris, J. S. Neville, and J. M. Thomson.

Edison's New Lamp.—As a general rule we do not care to reproduce interviews of Mr. Edison by representatives of non-technical papers, since it is usually hopeless to separate Mr. Edison's ideas from those of the reporter. The following, however, taken from an interview with a representative of the New York journal *Electricity* should be reliable, and shows pretty clearly the present position of things. It is plain that at present a tube has not been obtained which can be run continuously for any time. That is the important point. The description of platinum as the "base" in potassium platino-cyanide is a minor matter, but the use of the expression "ultra-violet sound-waves" shows how Mr. Edison's sound theory originated, and incidentally demonstrates the danger of semi-poetical descriptions of this character. Our New York contemporary says: "The tube was lit up a large number of times for our representative, but the current was kept on only for a few minutes at a time to prevent the deterioration of the vacuum. The lamp, Mr. Edison said, was giving about 2 c.p. He had run it up higher, but was afraid to do so as it was the only good tube he now had. He was having some larger ones made which he expected would give about 10 c.p. It was difficult to believe that the bulb shown was giving so little light, so deceptive are such things to the eye, but Mr. Edison insisted that it was giving no more. Asked as to the energy consumed, he said he had placed a Weston ammeter and voltmeter in the primary of the induction coil, and the readings were two amperes at $\frac{3}{10}$ of a volt. This would indicate only $\frac{3}{10}$ of a watt per candle-power, which is an extraordinary efficiency when we consider that three watts are a good efficiency for the incandescent lamp and half-watt for the arc lamp. He did not know what effect the self-induction of the coil had upon the readings of the instruments, and asked what effect it had in testing Moore's tubes. When the writer told him that his tests of the motor circuits described in our last issue gave very concordant but lower results than tests made in the interrupted circuit, he exclaimed with enthusiasm, 'Well, then, I am on the safe side.' Our representative told him that he did not think the error occasioned by self-induction was large, and upon being asked 'How large?' replied 'Probably not over 10 or 15 per cent.' Speaking of economy, our representative, turning to the huge induction coil, asked, 'How about that?' 'Oh,' said Edison, 'that's rotten; you've sounded the keynote exactly. This part (putting his hand on the tube) is all right—it is fine; but that part (pointing to the induction coil) is rotten.' Asked if he still maintained the theory that the X rays were sound-waves, he said that he did. That theory had sufficed for all of his experimental data, and so long as it continued to do so he intended to stick to it. He explained further that in a fluorescent salt the heavier element acted as a sort of fulcrum around which the lighter element vibrated. Thus, in the platino cyanides the cyanogen was the lighter element and the base the heavier. When this salt was struck by these ultra-violet sound-waves, the molecules as a whole could not be set in vibration, but the lighter radicle—the cyanogen—could, and in this way the substance emitted light."

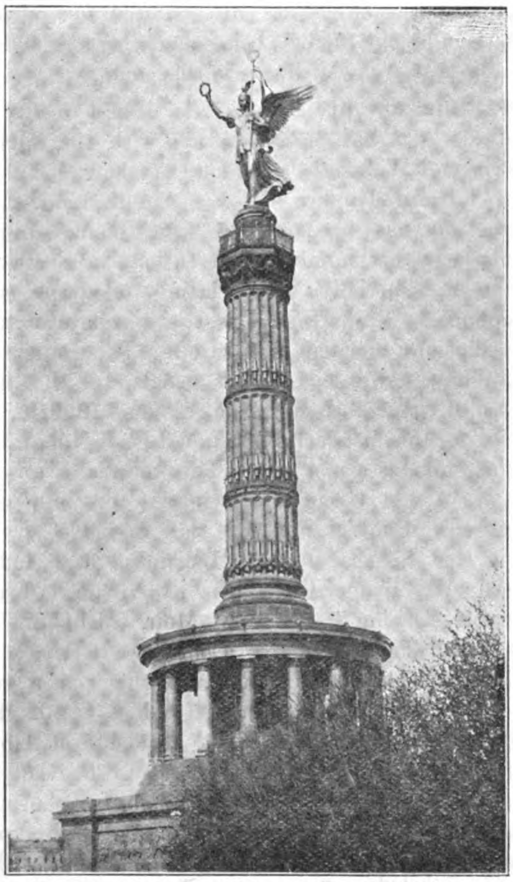
THE 1896 MEETING OF THE VERBAND DEUTSCHER ELEKTROTECHNIKER IN BERLIN.

(BY OUR SPECIAL CORRESPONDENT.)

It was with great pleasure that I received instructions to proceed to Berlin and to report for the *Electrical Engineer* the doings of the above society at their annual meeting. The anticipation of again enjoying the hospitality of the German engineers and once more meeting the friends made in Munich last year made me start early, in order to miss nothing of the proceedings. On my way through Cologne I was welcomed by Mr. C. P. Feldmann, of the Helios Company, and spent with him some happy and instructive hours. The gist of our conversation on the different systems of electric mains and their calculation will be found elsewhere. From Cologne to Berlin I endured 11 hours of a melting process, which considerably lowered my insulation resistance, although, at the same time, there was a slight increase in capacity. I travelled by the train which runs on to St. Petersburg, and although the arrangements were most comfortable, the dust accumulated in the carriages to such an alarming extent that it became a question whether the passengers would be visible when they reached Russia. The first evening spent in Berlin I was kindly invited by Mr. Gisbert Kapp, the able secretary of the Verband, to a private dinner, where I met the president, Prof. Slaby, and three active members of the committee—Dr. Budde (of Siemens and Halske), Mr. Naglo, and Mr. Jordan. After leaving the table I had a few minutes' most interesting conversation with Prof. Slaby concerning the state of the electric lighting industry in England. He was surprised to hear that the municipalities were taking up the supply of electric light with success, and assured me that in Germany it was rather an exception to find municipal enterprise up to date. So many undertakings owned by German town authorities are allowed to stand still without taking advantage of new improvements. Hence Prof. Slaby stated distinctly that such matters were better left in the hands of companies, whose interests lie in giving a cheap and efficient supply. I also gathered from him that the independent consulting engineer is more scarce in Germany, as there the most eminent consulting men also act as contractors at times, and hence are apt to establish business relations with certain firms. A town would thus have difficulty in finding engineers to advise them without at the same time putting themselves into a restricted market.

The general programme of the meeting was commenced on Wednesday, the 17th ult., by a social gathering in the Reichshalle, Leipzigerstrasse, when a thoroughly German entertainment was provided, in which the drinking of light German beer formed no inconsiderable part. The theatre consists of a large ground floor on one level, and one gallery only, with boxes in front. The ground floor was arranged with tables running full length, at which the gentlemen sat, while the ladies, dressed in gay attire, adorned the boxes. The programme commenced by a long welcoming speech from one of the authorities, which was followed by singing. A "Salamander" was then performed, which is certainly a feature unknown in England.

The Houses of Parliament, Berlin.



The "Siegessaale," Berlin, erected to commemorate the victories in the Wars of 1839, 1866, and 1871.

The first requirement of this performance is that every beer-jug shall be emptied. The jugs are then rattled together to a well-known tune, and finally crashed on to the

Digitized by Google

tables with a noise like a thunder clap. A series of short theatrical performances, in which the acting was admirably carried out by members of the electrical profession, were given at frequent intervals, interspersed by glee singing. Towards the end of the evening a dozen gentlemen, dressed as Spanish students, with the typical wooden spoon in their caps, came on the stage and sang "The Student of Cadiz." After the song was done, they scaled the boxes by means of ladders decorated with evergreens and distributed a fan and bunch of roses to each lady. Another interesting skit was that designed to imitate a recently-invented type-

Potential Difference.

Capacity.

setting machine on view in the Berlin Exhibition. A man seated at the machine was supposed to control it by his thoughts, and the sparks given out by the type-setter showed the rate at which the work was proceeding. At one period of the run the machine gained in speed and emitted a howling noise due, as the demonstrator explained, to the fact that the operator had made use of a pun. The machine was next supposed to print off the *Bier Zeitunq*, which was immediately distributed amongst the guests. This beer journal is a most artistic production and the literary work in it is also exceedingly amusing, although the point of several of the advertisements cannot be understood without local knowledge. The following

Insulator.

Pressure.

Short Circuit.

will give a general idea of the style of advertisements at the end of the paper:

WANTED, immediately, an ELECTRICAL COOK, with college diploma, well up in Maxwell's Theories and used to repairs, for looking after an electrical stove.

OBJECTIONS to the INTRODUCTION of ELECTRICAL TRAMS KEPT IN STOCK in great variety.—Apply, THE MUNICIPAL AUTHORITIES OF BERLIN.

WANTED, TO BUY an ELECTRICAL INCUBATOR, to HATCH NEW PROPOSALS for LEVYING TAXES.—Apply to the CHANCELLOR OF THE EXCHEQUER.

ELECTRICAL WORKS OF FERD, SENGERICH, AND CO., Berlin, Department I.—Electric Railways, System Wertheim.—ONE MILE GIVEN AWAY with each 12 miles ordered. Price-reducing valves. Attractive surprises for chief engineers.

The body of the journal shows no great respect to the electrical profession generally. Thus the first article is a

Magnetic Attraction.

description of the Berlin Exhibition, with illustrations, and the view of the grounds on the second evening shows that total darkness reigned supreme. The illustrated electrical scenes are most carefully prepared, but suggest that the editor of the *Bier Zeitung* was no amateur in the art of imbibing. The Pelton wheel used as the prime mover in the polyphase transmission scheme bears out this latter view. The pleasant evening was only marred by the heat, which was almost unbearable.

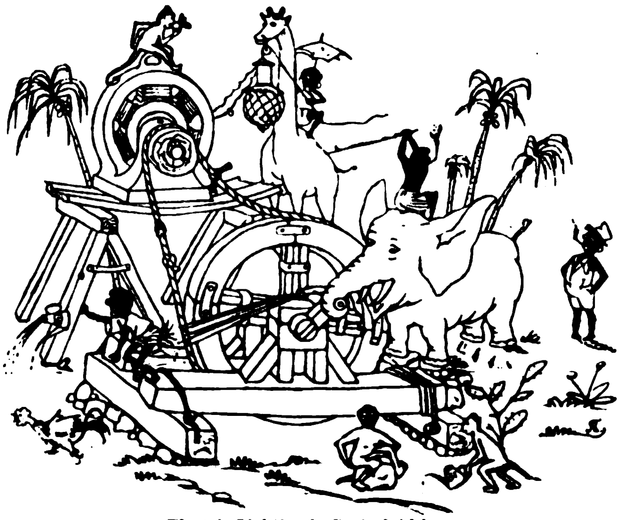
A Polyphase System.

The public business of the meeting began on Thursday, June 18, in the Architektenhaus, Wilhelmstrasse. At it there was a large gathering of men who have taken an active part in the development of the electrical industry in Germany. I was pleased to find there a number of engineers from Vienna whom I met at Munich last year.

Interview with Mr. C. P. Feldmann, of Cologne, on Electric Light Mains.

On my way through Cologne *en route* for Berlin I spent a few pleasant hours in the company of Mr. C. P. Feldmann, the chief electrician of the Helios Company. He kindly showed me over the Cologne electricity works, which contains the flywheel alternators manufactured by the above firm. These works may justly claim to have originated the use of flywheel dynamos direct coupled to slow-speed horizontal engines. It was in these works that Mr. A. Colson, of Leicester, obtained his conviction that this system was the correct one for Leicester, and his example was followed afterwards by other engineers.

Mr. Feldmann has devoted great attention to the calculation of electric mains and networks, and the following *résumé* of our conversation on the subject will be of interest. Mr. Feldmann considers that the first man to publish a technical article upon the calculations of electric mains, after Lord Kelvin and Prof. Forbes, was Mr. C. Hochenegg, who in 1887 made public a graphical method of investigating the drop of simple examples of ring distribution. In 1891, Mr. J. Herzog, of



Electric Lighting in Central Africa.

Budapest, in conjunction with Mr. L. Stark, took the matter up and investigated completely a physical and not merely mathematical method of calculation for electric systems of distribution. The method employed

Digitized by Google

starts from the fact that in each closed ring or mesh there must be one consumer who gets current from either side. This was known, of course, before 1891, and there were several methods of trial and error in use to find this place where the mesh may be thought cut without altering for a given consumption the supply currents in either part. Several engineers were looking for some simple way of finding the supply currents without the laborious trial and error method, but Messrs. Herzog and Stark showed clearly that the section may be taken anywhere in the mesh; the simple equation shows that the drop in E.M.F. either way round the mesh from the given feeding point to the assumed section is equal, giving not only the real section but also the real distribution of supply for the given consumer. Later on Messrs. Herzog and Feldmann enlarged the method, and developed a complete system of calculation on paper on undue loads on any given branch of any network. In their book, called "Berechnung elektrischer Leitungsnetre in Theorie und Praxis"—*i.e.*, "Calculation of Electric Networks in Theory and Practice"—their system is fully described, and the system is also referred to in our columns.*

Mr. Feldmann agreed with me that the treatment without practical experience would be cumbersome, but when combined with a previous knowledge of the subject, an extremely well-balanced network could be easily designed. His procedure in laying-out a new town is roughly as follows: The main streets are selected, and together with those side streets likely to provide consumers, are marked on a convenient scale. The probable consumption in these streets can be approximately determined from the previous

MR. C. P. FELDMANN.

consumption of gas, or from a general knowledge of the character of the town, the country, and the customs of the people. Mr. Feldmann then proceeds to lay down complete rings of mains in these streets to supply the presupposed load, and then tests the distribution of current in the various branches by the above methods. The section of the mains is thus chosen according to experience, and changed if the distribution found requires it. It must be remembered that the engineer only cares for the current in the sections and the drop of voltage, and does not care at all for the resistance of the individual sections. Mr. Feldmann was directly opposed to the practice of using a low-pressure network with alternate-current distribution. He admitted that the no-load losses in the transformers would be higher if individual transformers were placed in the consumers' houses, and that the ratio of units sold to units generated could also be increased by the use of low-pressure distribution. He objected to this latter system on the ground of first cost, and because the good regulation of a high-pressure distribution was nullified in the low-pressure mains. In his opinion, when good transformers are used, the increased cost of magnetising the larger number of small transformers would be more than counterbalanced by the additional charges for interest on capital and depreciation on the low-pressure system, the increase of capital being caused by the secondary network and the transformer sub-stations. He thought that none of the systems worked out so far for switching of transformers would really work in daily practice, and that especially in Germany the risk of interference with telephone circuits was also largely increased by using a secondary network. With single transformers any consumer may have earth on his circuit without disturbing his neighbour or the telephones. With a secondary network the whole of the customers and telephones may be annoyed by two or three earths, which cannot be avoided in a low-pressure network.

I afterwards proceeded to question Mr. Feldmann about the series system of lighting introduced by the Helios Company. He told me that their managing director, Mr. Carl Coerper, devised the scheme for the lighting of Kiel Canal in 1893. The main feature of this system is that of placing a choking coil in parallel with each lamp. If, then, from any causes the lamp goes out the choking coil immediately takes up the whole current of the circuit, and at the same time keeps the voltage constant.* The lighting of the Kiel Canal with incandescent lamps showed the utility of the system. Although the canal is over 60 miles long, only two generating stations are used, and there are only four series circuits of lamps. Each circuit consists of some 250 25-volt lamps in series, the total voltage of the whole circuit being 7,500. The current taken by the lamps is three amperes, while the choking coils take from six to seven, but the current through the choking coil being almost at right angles (in phase) to that through the lamp, the whole current of the circuit is only about 7·5 amperes. The elasticity of this system is such that 30 per cent. of the lamps can be extinguished without requiring any regulation of the generators to prevent an excess current in the other lamps. The extra load taken by the circuits to keep the choking coils excited is about 10 per cent., which loss can be well afforded on account of the great saving in capital charges due to the simplicity of this system. Although the lighting at the Kiel Canal is done by incandescent lamps, Mr. Feldmann assured me that Mr. Coerper's arrangement was equally good for arc lighting. When six arc lamps are connected in series with choking coils across their terminals, two of the lamps can be switched out without affecting the others or requiring any alteration in the voltage of the supply. The Helios Company are applying this system for street-lighting with arc lamps in series of 200-volt transformers, and find that the choking coils assist the regulation of the lamps considerably; they have even burnt 20 lamps in series, of which six to seven might be extinguished.

(To be continued.)

RAILWAY BLOCK SIGNALLING.

BY J. PIGG.

The "block" telegraph system in use for regulating traffic is probably the most extensive of all the adaptations of electricity to railway work, and its "use-value" is undoubtedly greater than that of any other form of electrical apparatus in use upon railways. The development of the "block" system has been the work of the last 30 years approximately; previous to that time traffic was worked in quite a different fashion to that in use at present.

The fundamental principle of the "block" was at first derided, and the name chosen was considered as characteristic of the condition traffic was likely to get into under any such system of working. That there should be any reason to prevent a driver from proceeding as far as his visionary powers assured him the line was clear, or that any train should be prevented from "bumping" a preceding train—gently, of course—was considered absurd, and there were not wanting those who predicted the early demise of this or any other system which involved restrictions being put

* "The Cologne Electricity Works," *Electrical Engineer*, vol. xvii., pages 89, 120, and 231.

* According to theory, it should require a higher voltage to keep constant currents, but then, luckily, the self-induction coefficient is not constant, but varies in well-designed apparatus.

Digitized by Google

on the free passage of traffic. This, of course, was before the era of express trains travelling at rates varying between 60 and 70 miles per hour. In those days it was no uncommon thing for agile persons to boast of their ability to leave trains at any point that was most suitable. At that date railways were comparatively small concerns compared with what they have, by extensions and amalgamations, now become, and the volume of traffic handled by one railway was correspondingly small.

The prophecies referred to have, however, been falsified, and railway traffic is now carried with a regularity and freedom from accident which is remarkable when the quantity of material handled and the area covered is taken into consideration. To this precision, and the safety resulting therefrom, the "block" has undoubtedly contributed quite as much as any other branch of engineering.

The first example of an electrical signalling instrument in use with which the writer became acquainted is that shown by Figs. 1 and 2. These instruments were patented by Alex. Bain, and were in use between the ends of a tunnel on the old Stockton and Darlington Railway, and were replaced by C. V. Walker's block instruments about 1868. The instruments were provided with bells, not shown, the hammers of which were held up by trip-gear, which was released by the deflection of the needle, the hammer being raised again, by hand, after every stroke.

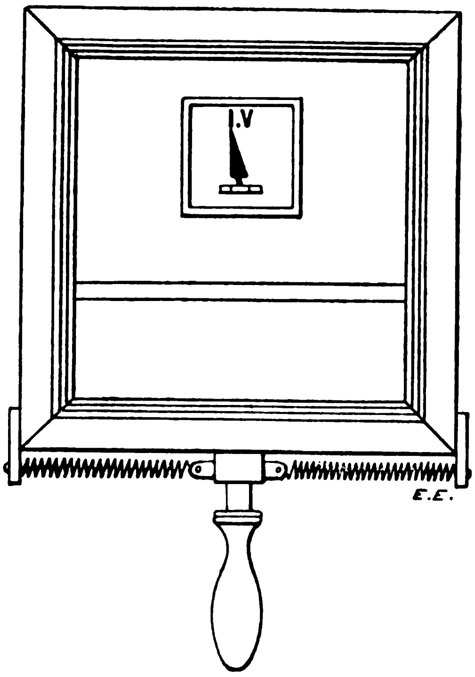


FIG. 1.—Alexander Bain's Signalling Instrument.

CODE OF SIGNALS AND ALPHABET.

Yes	A	I	IVI	O	Is an engine near
Engine out	B	II	IVII	P	Send train on main-way
Two engines	C	III	IIVI	Q	Stop traffic on main-way
Three engines	D	IIII	VVI	R	Repeat the last letter
I understand	E	V	IVV	S	Do you understand
Engine entered	F	VV	VIV	T	Wagons left in
Stop traffic on by-way	G	VVV	VVVI	U	Is all out
	H	VVVV	IVVV	V	No tail signal
No	I	IV	VIVV	W	Hagger leases
I am going to speak in			VVIV	X	Train on main-way
letters	J	IIV	VVII	Y	All is right
Engine returned back	K	IIIV	VIVI	Z	I am showing the telegraph to a friend
Is all right	L	VI			
Train on by-way	M	VII	IVIV		Stop traffic on by-way
Sent train on by-way	N	VIII			

RULES TO BE OBSERVED.—1st. The bell is to be rung at the commencement of every conversation.—2nd. The V in the course of conversation always to form part of it and to be considered as the bell.—3rd. At the close of every conversation the bell handles must be set for ringing.—4th. The plates of the battery must be put into the trough at the beginning of the conversation and taken out when finished.

The code of signals in use for ordinary work and the alphabet for conversation on matters not provided for in the code are given, together with the rules. The signal, "I am showing the telegraph to a friend," and the rule, "The plates of the battery must be put into the trough at the beginning of the conversation and taken out when finished," are very quaint, and would be difficult to duplicate at present. The signal, "Engine returned back," is also significant of the free and easy manner in which things were carried on in the earlier days of railways.

"Block" working may, for convenience, be divided into two main parts, "absolute" and "permissive." "Absolute" block may again be divided into "double-line" and "single-line" working, as the requirements for these are somewhat different.

Absolute block working consists essentially in preserving a certain space between successive trains on the same line of rails, this space varying in different localities from a few miles to, perhaps, 300 or 400 yards, or less, according to the amount of traffic, the number of junctions, and the distance between them.

Permissive block working imposes a space limit, not between individual trains, but between groups of trains only. With absolute block working two trains in one section on the same pair of lines are not permissible; with the permissive block any number of trains up to a prearranged limit may be admitted into a section.

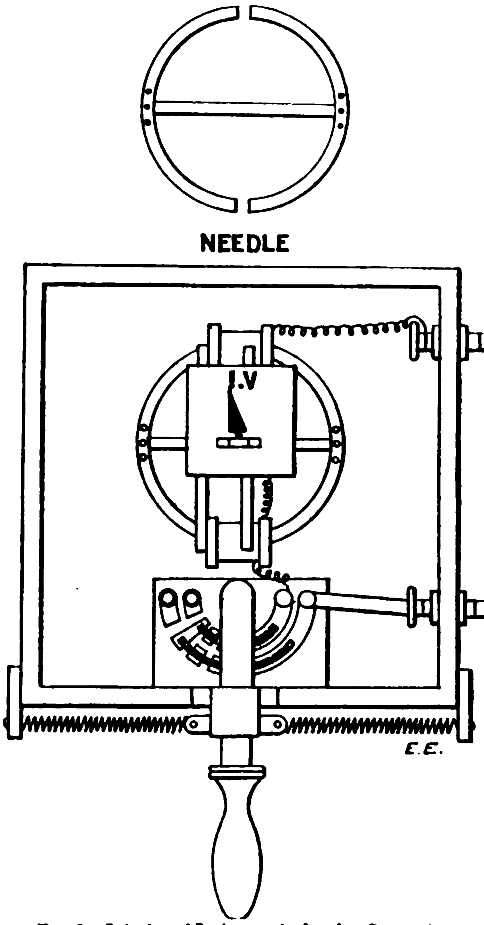

FIG. 2.—Interior of Instrument, showing Commutator.

In order to carry out either system of block working, cabins are built at suitable points on the line side, and in these cabins the apparatus for working the outside mechanical signals which control the passage of trains into or out of the sections, and the "block" apparatus for indicating the condition of the lines and for sending the various signals required between the two ends of a section, are placed. As pointed out in a previous article, the receiving end of a section of line is of much greater importance than the sending end, but a cabin which is the sending end for "up-line" trains will be the receiving end for "down-line" trains, and thus the average responsibility is equal, and the disparity only exists in considering individual trains.

At one time considerable discussion centred on the most suitable form of instrument for indicating the condition of the line. Some inventors pinned their faith to instruments in which the indicator was a small semaphore arm, or a fac-simile in miniature of the outdoor mechanical signal, and argued that the train distinguishing signalling apparatus should be of a different character to the indicating apparatus, but not necessarily a separate instrument, since they served distinct purposes, and that uniformity in design of the mechanical signals and the block indicator was desirable in many respects. Others, again, preferred some form of the "needle" instrument, so familiar on railways, and con-

Digitized by Google

tended that the indication was in any case arbitrary, and consequently when once established and understood the character of the indication was immaterial. It was further contended by the advocates of the single-needle instrument that it allowed a greater variety of signals to be sent, and that it also possessed the further advantage of cheapness.

Intimately connected with the most suitable character of block indicator is another point which seems to have been considered of some importance by inventors of block apparatus, and upon which much ingenuity has been exercised. This is the reduction of the number of line wires to one, and the ability to perform all the operations required for double-line block working by one line wire is still often urged as a recommendation on the score of smaller cost for erection of wires and their maintenance.

Before discussing the suitability of any particular form of instrument, it is necessary, in order to arrive at a proper understanding of the requirements, to know something of the traffic arrangements. Most people are acquainted with the broad principles of block working, but few outside the railway service have more than a superficial acquaintance with the actual working of the system on a large railway. The comments of the average layman on the breakdown of arrangements which may have led to an accident have generally to be heavily discounted on account of his evident lack of knowledge of the subject, and are to be regarded as evidence of courage more than of experience.

Railway traffic is divided into classes, the relative importance of which are defined in the regulations of the various companies. Thus, express passenger trains take precedence of all other classes, and any train of another class which is likely to delay an express passenger train must be shunted to allow the latter to pass. Again, ordinary, or slow passenger trains, take precedence of all trains except express passenger trains. Trains conveying perishable goods (fish, yeast, butter, fresh meat, etc.), or goods for a special market, take precedence of all trains except passenger trains. Express goods trains conveying through traffic only come next, and after these "through mineral," "pickup goods," "slow mineral," "ballast trains," etc.

The more important trains carry some distinguishing board during the day and a particular arrangement of headlights at night to indicate their character to those regulating the traffic. Each class of train has its own distinctive signals on the block apparatus, and, in addition, the more important trains have their time of departure from certain stations telegraphed forward to different points on their route, so that arrangements may be made to ensure a clear course for them without unnecessary delay to other traffic, which might, in the event of an important train being behind its scheduled time, be kept waiting unnecessarily.

It will be readily seen from the foregoing that a considerable variety of signals will be necessary for the working of traffic; and in addition to these there are others which are designed to meet such emergencies as experience shows as likely to arise, and for special purposes other than traffic working proper. Signals may, therefore, be divided into three classes: (*a*) those for ordinary working; (*b*) those for emergencies; (*c*) those for special purposes.

The ordinary signals may be further divided into three classes: those which are preliminary to the entrance of a train into the section, and which partake of the nature of a request for permission to send a train forward; those which notify the actual entrance of a train into the section; and those which notify that a train previously signalled has passed out of the section.

The emergency signals are of a different character, and consist for the most part of bell signals, codes of rings being established to convey information on special points of importance. Of this class are such signals as the "Obstruction danger signal," "Stop and examine train," "Vehicles running away on right line," "Vehicles running back on wrong line," "Train passed without tail lamp," etc. The third division consists of such signals as indicate testing of the block apparatus, or controlled mechanical signals, "time signal" and others which, whilst of some importance in their way, are not directly connected with the working of traffic.

Passing from the general to the particular, it may be said that on one large railway worked on the three-wire "needle" block system the number of bell signals was 19 and the number of dial signals was 16 prior to April, 1895. Of the former, four were of the nature of an enquiry, or the preliminary "Be ready" signal for as many different classes of trains, six were emergency signals, one "Train entering section" signal, and eight special signals. Of the dial signals, 12 were for distinguishing the various classes of trains when sent on line, one was "Line clear" signal; two were for shunting purposes, and one was to indicate the necessity for forwarding the next train at "Caution."

A revised code of signals has recently been brought into operation, and a comparative study of the old and new codes reveals an increase in the number of signals of all kinds from 35 to 45. The number of bell signals has increased from 19 to 31, whilst the dial signals have decreased from 16 to 14.

Of the bell signals under the revised code, one is for "Attention," 11 are of the nature of an enquiry or "Is line clear for, etc.," this form being substituted for the "Be ready" of the previous code, one "Train entering section," seven emergency signals, and 11 special signals. Of the 14 dial signals, six are descriptive of trains and five are special signals. On another large railway, also worked on the three-wire block, the whole of the signals, numbering 34, are given upon the bell, and the dial instruments are used as indicators of the condition of the line only.

It will be readily seen from the foregoing, without further analysis of the codes of signals, that the transmission of signals indicating the character of approaching trains is an important function of block apparatus, and, further, that the tendency at present seems to be to increase the number of signals to be transmitted. Block instruments, therefore, to give general satisfaction on lines carrying a great variety of traffic, must be such as to allow of a corresponding variety of signals, without unnecessarily cumbrous or intricate codes, in order that the various classes of trains may be distinguished from each other.

(To be continued.)

THE PRINCIPLES OF ALTERNATE-CURRENT WORKING.*

BY ALFRED HAY, B.Sc.(EDIN.), A.I.E.E.

(Continued from page 692.)

9. All physical quantities may be divided into two classes—viz., *scalar* and *vector* quantities. A *scalar* quantity has *magnitude*, but no direction. A *vector* quantity possesses both *magnitude and direction.* Thus, a sum of money, the temperature of the water or steam inside a boiler, the power of an engine, are all examples of *scalar* quantities. The characteristic of a scalar quantity is that it is possible to specify it completely by a simple number. On the other hand, the magnetic force at any point, the velocity of a moving body, the magnetic induction at any point of a mass of iron, are examples of *vector* quantities, and something more than a single number is required to specify them completely. Thus, if we take magnetic force, a single number would merely tell us what the intensity of the force is, without, however, informing us as to the *direction* in which it acts. Vector quantities, then, are quantities having direction in space. Now, direction may be represented by a straight line drawn in space. This at once suggests that we may make use of straight lines to represent vector quantities. The direction of a vector quantity is represented by a straight line with an *arrow-head* affixed to it. Further, the *magnitude* of a vector quantity is easily represented to any convenient scale by the *length* of a line, so that we have a method of representing vector quantities completely (both as regards magnitude and direction) by straight lines of definite length with arrow-heads attached to them.

Thus, let O A (Fig. 7) be a straight line of length 10, and let us suppose that it represents the magnetic force at the point O. The direction of the force is indicated by the direction of the line O A and its arrow-head. The magnitude

* Based on a series of evening lectures delivered at the University College, Liverpool.

Digitized by Google

of the force is 10, if we suppose each unit of length to correspond to a unit force. The force is therefore completely specified by the straight line O A.

Vector quantities are frequently, for the sake of brevity, termed *vectors* simply, and the same term is applied to the lines representing them. In what follows, we shall frequently apply the term "vector" to denote a straight line of definite length, with an arrow-head at one end of it.

10. Hitherto we have regarded vectors (in the sense last named) as representing certain *quantities*. But there is another way of looking at them which is very instructive, and which will enable us easily to deduce some important results concerning them. We may, in fact, regard a vector as an *operator*, and the operation which we suppose it capable of performing is that of transferring a point from a given position in space to another position, through a distance equal to that of the vector, and in a direction parallel to it. Thus, the result of applying the vector O A (Fig. 7) to the point P is to transfer the point from P to P′, where P′ is such that P P′ is equal and parallel to O A.

It may be as well at this stage to draw the student's attention to the fact that when a vector is denoted by two letters, such as O A in Fig. 7, the last letter always refers to the extremity of the vector to which the arrow-head is attached. Hence A O would denote a vector parallel and equal in length to O A, but with its arrow-head pointing in the opposite direction, as shown by the dotted line A′ O′ in Fig. 7.

Let us apply the vector O A to the point P; this will transfer P to P′. Next, let the vector A O be applied to P′. This will bring P′ back to its original position P. Thus the successive application of the two vectors O A and A O produces no resultant effect. Hence we may write $\overline{OA} + \overline{AO} = 0$, or $\overline{OA} = -\overline{AO}$, where the bar above the letters is used to indicate that they denote vectors, and not mere lengths.

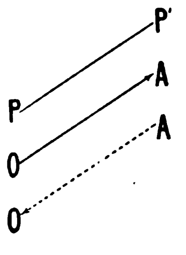

FIG. 7.

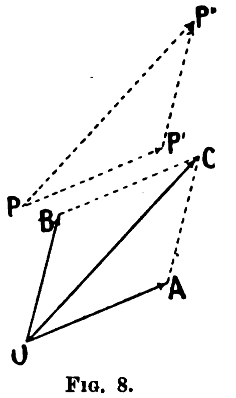

FIG. 8.

11. We may now consider the result of applying any two vectors, O A and O B (Fig. 8), to a given point P. Applying first the vector O A, we transfer P to P′, where $\overline{PP'} = \overline{OA}$; next, applying O B, we transfer P′ to P″, where $\overline{P'P''} = \overline{OB}$. The final result, then, is to transfer P to P″. But this might have been accomplished more simply by at once transferring P to P″ along the straight line P P″. Now $\overline{PP''} = \overline{OC}$, the diagonal of the parallelogram constructed on O A and O B as sides. We thus have $\overline{OA} + \overline{OB} = \overline{OC}$, a result which is generally referred to as the *parallelogram law* for the addition of vectors. Again, we have $\overline{PP'} + \overline{P'P''} = \overline{PP''}$. This result is sometimes spoken of as the *triangle of vectors*.

It will, of course, at once be seen that the above result only applies to the lines O A, O B, etc., when these are *considered as vectors*, and not as mere lengths, in which latter case it obviously does not hold.

The law of addition just established for two vectors may be extended to any number of vectors. Thus, let $\overline{OA}$, $\overline{OB}$, and $\overline{OC}$ (Fig. 9) be applied to the point P in succession. The result is to transfer P to P‴ along P P′ P″ P‴. The same result is obtained by the direct application of the single vector P P‴. We thus have $\overline{PP'} + \overline{P'P''} + \overline{P''P'''} = \overline{PP'''}$, a result known as the *polygon of vectors*.

The law established above for the composition of vectors at once provides us with a method for finding the resultant of any number of vector quantities. We thus have the triangle (or parallelogram) and polygon of velocities accelerations, forces, etc.

12. From what has already been said regarding projection (Art. 6), it will be understood that the projection of a vector on a given straight line is equal to the product of the vector into the cosine of its angle of inclination. Also, the sum of the projections of any two vectors is equal to the projection of their resultant.

13. We now proceed to the study of certain kinds of motion which will be found to be of very great importance in connection with our subject. The two motions which we shall have to consider are known as *uniform circular motion* and *simple harmonic motion* respectively.

Let a point P (Fig. 10), starting from the position A, move with *constant speed* round the circumference of the circle A B C D in a counter-clockwise direction. The motion of P is said to be *uniform circular motion*. As P moves along the circumference of the circle, the radius O P traces out the angle A O P, which increases at a constant rate. The amount by which the angle A O P increases in a unit of time is termed the *angular velocity* of O P. Angular velocity is commonly expressed in *radians per second* (Art. 2). Let us suppose that the angular velocity of O P is p, and let v stand for the speed of P. Then, since the length of arc described by P in one second is v, and the radius of the circle is equal to O P, the angle swept out by O P in one second is $\frac{v}{OP}$; but this is, by definition, the angular velocity of O P—*i.e.*, p. Hence,

$$p = \frac{v}{OP}, \text{ or } v = p \cdot OP \quad . \quad . \quad . \quad (11)$$

i.e., the speed of P is obtained by multiplying the angular velocity by the radius of the circle.

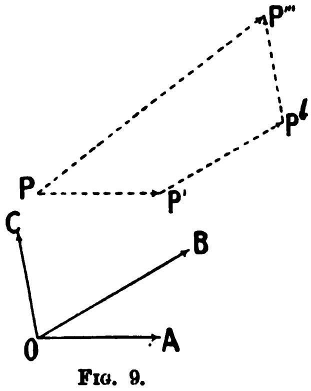

FIG. 9.

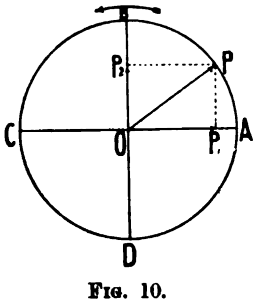

FIG. 10.

14. Consider the projection of P (Fig. 10) on any fixed straight line, such as the horizontal diameter C A of the circle. Let P_1 denote the projection of P on this diameter. As P moves round the circumference of the circle its projection P_1 *oscillates* to and fro along the diameter C A. This oscillatory motion of P_1 is called a *simple harmonic motion*. We thus define *simple harmonic motion* as the *projection on any fixed straight line of uniform motion in a circle*. Every simple harmonic motion must therefore be capable of being referred to a corresponding uniform motion in a circle, and this circle is termed the *auxiliary* circle.

The time of a complete revolution in the auxiliary circle is called the *periodic time*, or simply the *period*, of the simple harmonic motion.

The radius of the auxiliary circle is termed the *amplitude* of the simple harmonic motion.

15. The two motions which we have just considered may be represented by means of two vectors as follows. Uniform circular motion may be expressed by a vector of constant length, one of whose extremities is fixed, while the other moves round the circumference of a circle with constant speed. Simple harmonic motion may be represented by another vector, which is the projection, on a fixed straight line, of the first vector. Following Prof. Galileo Ferraris, we shall call the first vector a *rotating vector* and the second an *alternating vector*. A rotating vector is constant in length, but variable in direction; an alternating vector is variable

Digitized by Google

in length, but its direction is always along the same straight line.

Consider two alternating vectors of the same period. At any instant, the alternating vectors will be inclined at certain angles to their corresponding rotating vectors. If the two angles are equal we say that the two alternating vectors are in the same *phase*; if the angles are different the constant difference between them is called the *difference of phase* between the two alternating vectors.

16. We shall now obtain an algebraical expression for an alternating vector. If we suppose that the line in which the alternating vector lies is given, its length at any instant may be expressed by a number, with the *plus* or *minus* sign attached to it. In accordance with the convention regarding signs (Art. 1), a plus sign indicates that the vector has its arrow-head pointing in one direction, a minus sign that it is pointing in the opposite direction. Referring to Fig. 10, let us suppose that a rotating vector O P, of length R, starts from the position O A, and moves round with angular velocity p. Let A O P be the angle swept out in t seconds. Then A O P $= p\,t$. Consider the alternating vector O P_1 obtained by projecting O P on the horizontal diameter. Let $r_1 = \mathrm{O\,P_1}$. Then

$$r_1 = \mathrm{O\,P_1} = \mathrm{O\,P} \cos \mathrm{A\,O\,P};$$
$$= \mathrm{R} \cos p\,t \quad . \quad . \quad . \quad . \quad . \quad (12)$$

Again, consider the alternating vector O $P_2 = r_2$, obtained by projecting O P on the vertical diameter. We have

$$r_2 = \mathrm{O\,P_2} = \mathrm{O\,P} \cos \mathrm{B\,O\,P};$$
$$= \mathrm{O\,P} \sin \mathrm{A\,O\,P}, \text{ by (5)}$$
$$= \mathrm{R} \sin p\,t \quad . \quad . \quad . \quad . \quad . \quad (13)$$

From (12) and (13) we see that an alternating vector may be expressed as the product of two quantities, one of which (R) is a constant, while the other is the *sine or cosine of an angle which varies at a constant rate with the time.*

will be an alternating vector. We have thus established the following proposition:

The resultant of two alternating vectors of the same period and in the same straight line is another alternating vector, also of the same period and in the same straight line.

A glance at Fig. 11 also reveals the fact that the resultant vector is intermediate in phase between its two components.

19. We shall next obtain an algebraical expression for the resultant of the two vectors. Let us suppose that at the commencement the rotating vector O A occupies the position O P. After time t, it will have swept out an angle P O A $= p\,t$, if p stand for the angular velocity. Calling the angle A O B between the two rotating vectors θ, we see that at time t the vector O B makes an angle P O B with the horizontal axis equal to $p\,t + \theta$. Denoting the lengths of O A and O B by A and B respectively, and projecting on the vertical axis, we find

$$\mathrm{O\,A_2} = \mathrm{A} \sin p\,t,$$

and $\mathrm{O\,B_2} = \mathrm{B} \sin (p\,t + \theta) = \mathrm{B} \sin p\,t \cos \theta + \mathrm{B} \cos p\,t \sin \theta$, by (8).

The resultant of these two vectors is obtained by projecting O C on the vertical axis. Denoting the angle A O C by a, and the length of O C by C, we get

$$\mathrm{O\,C_2} = \mathrm{C} \sin (p\,t + a),$$
$$= \mathrm{C} \sin p\,t \cos a + \mathrm{C} \cos p\,t \sin a, \text{ by (8).}$$

Now we have $\mathrm{O\,C_2} = \mathrm{O\,A_2} + \mathrm{O\,B_2}$—*i.e.*,

$$\mathrm{C} \cos a \,.\, \sin p\,t + \mathrm{C} \sin a \,.\, \cos p\,t$$
$$= (\mathrm{A} + \mathrm{B} \cos \theta) \,.\, \sin p\,t + \mathrm{B} \sin \theta \,.\, \cos p\,t.$$

Comparing coefficients of $\sin p\,t$ and $\cos p\,t$ on both sides, we see that

$$\mathrm{C} \cos a = \mathrm{A} + \mathrm{B} \cos \theta \quad . \quad . \quad . \quad (14)$$

and

$$\mathrm{C} \sin a = \mathrm{B} \sin \theta \quad . \quad . \quad . \quad . \quad . \quad (15)$$

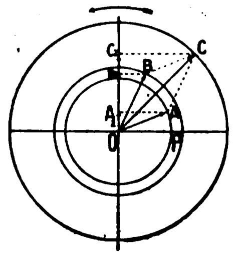

FIG 11.

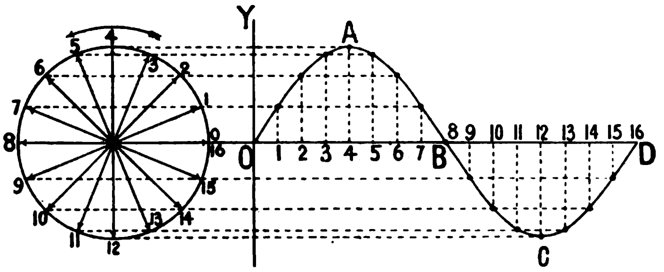

FIG. 12.

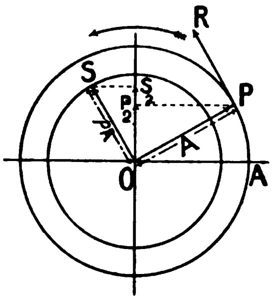

FIG. 13.

17. In order to express the *period* T of an alternating vector in terms of the angular velocity p, we have merely to notice that the angle described by the rotating vector in one period is $2\,\pi$ (*i.e.*, four right angles). Hence $p\,\mathrm{T} = 2\,\pi$, so that $\mathrm{T} = \frac{2\,\pi}{p}$. Also, if n stand for the number of complete periods per second, we have $\mathrm{T} = \frac{1}{n}$; hence $p = 2\,\pi\,n$.

18. We are now in a position to consider the problem of finding the resultant of two alternating vectors in the same straight line and of the same period. Let O A and O B (Fig. 11) represent the two rotating vectors from which the alternating vectors are derived. Since the two vectors are of the same period, O A and O B will revolve round O with the same angular velocity, so that the angle A O B between them will remain unaltered. This angle is termed the *angle of phase difference* between the two vectors (Art. 15); we may otherwise express this by saying that the alternating vector derived from O A *lags* behind that derived from O B, and that A O B is the *angle of lag*. Let us suppose that the alternating vectors are obtained by projecting the rotating vectors on the vertical axis. At any instant the *resultant* of the two alternating vectors is the sum of the projections of O A and O B on the vertical axis; but (Art. 12) this is the same as the projection of O C, the diagonal of the parallelogram constructed on O A and O B as sides. Now since the angle A O B remains constant, O C will remain of constant length, and will revolve about O with the same constant angular velocity as either of the two vectors O A and O B. Hence O C will be a *rotating* vector, and therefore its projection on the vertical axis

Dividing (15) by (14), we get

$$\tan a = \frac{\mathrm{B} \sin \theta}{\mathrm{A} + \mathrm{B} \cos \theta} \quad . \quad . \quad . \quad (16)$$

Squaring (14) and (15), adding, and remembering that $\cos^2 a + \sin^2 a = 1$, we get

$$\mathrm{C}^2 = \mathrm{A}^2 + \mathrm{B}^2 + 2\,\mathrm{A\,B} \cos \theta,$$

or

$$\mathrm{C} = \sqrt{\mathrm{A}^2 + \mathrm{B}^2 + 2\,\mathrm{A\,B} \cos \theta}.$$

We therefore have this result—

$$\mathrm{A} \sin p\,t + \mathrm{B} \sin (p\,t + \theta)$$
$$= \sqrt{\mathrm{A}^2 + \mathrm{B}^2 + 2\,\mathrm{A\,B} \cos \theta} \times \sin (p\,t + a),$$

where a is determined by equation (16).

20. The variations of an alternating vector with the time may be represented graphically by plotting a curve whose abscissæ correspond to time, and whose ordinates represent the corresponding instantaneous values of the alternating vector. This is easily done by the method shown in Fig. 12. Let the circle represent the path of the moving extremity of a rotating vector, and let O D and O Y be the two co-ordinate axes. Divide the circumference into any convenient number of *equal* parts. Since the rotating vector moves with constant angular velocity, each division of the circumference will correspond to the same interval of time. Along the time-axis O D lay off a number of equal lengths, O 1, 12, 23, etc. Let each of these divisions represent a time-interval equal to that corresponding to one division of the circumference. Through the points of division on the circumference draw lines parallel to the axis of time; the intersections of these lines with the corresponding perpendiculars drawn through the points 1, 2, 3, etc., on the time-

Digitized by Google

axis obviously determine a number of points on the curve required, since the instantaneous values of the alternating vector are determined by projecting the rotating vector on the vertical axis. By drawing a continuous curve through the points so determined we obtain the curve O A B C D, which shows at a glance the way in which the alternating vector varies as time goes on. The time-interval represented by the length O D is obviously equal to the period.

21. Every alternating vector, as we have seen, is capable of being exhibited as the product of two factors, one of which is a certain constant quantity (the *amplitude* of the vector), and the other the sine of an angle which varies at a constant rate as time goes on (Art. 16). Hence the curve O A B C D really represents the variations in the sine of an angle as the angle is varied, the values of the sine being, however, multiplied by the amplitude of the vector. Now, if we multiply each ordinate of a curve by a constant quantity, we merely alter the *scale* of the vertical axis without altering the character of the curve. Hence all such curves as O A B C D are called *sine curves*, or *simple harmonic* curves. One of the characteristics of such curves is that any one of them is capable of being transformed into any other by merely altering the horizontal and vertical scales of the diagram.

22. Any function of the time which is capable of being represented by an alternating vector is termed a *sine* function, or a *simple harmonic* function, of the time. If, for example, we speak of an alternating E.M.F. as being a sine function of the time, we thereby mean that it varies as time goes on according to the law represented by the curve O A B C D in Fig. 12.

In what follows we shall frequently have to deal with the *rate of change of an alternating vector*. In Article 7 it was explained that if we suppose the graph of a function to be recorded by a tracing point, the rate of change of the function *at any instant* is represented by the velocity of the projection of the tracing point on the vertical axis. Referring to Fig. 13, let O P represent a rotating vector of length A, and angular velocity p. Its projection O P_2 on the vertical axis at any instant gives us an alternating vector, whose rate of change *at the same instant* is represented by the velocity of its extremity P_2. Now the velocity P R of P is, by Article 13, equal to p A. From O draw a line O S equal and parallel to P R. Then O S represents the velocity of P at the instant considered, and hence the velocity of P_2, the projection of P, will be obtained by projecting O S on the vertical axis. Thus O S_2 gives us the rate of change of the alternating vector at the instant when the latter has the value O P_2, and is increasing. Now since the speed p A of the point P remains constant, O S will be a vector of constant length = p A. Also, since O S is always at right angles to O P, O S will revolve round O with constant angular velocity p—*i.e.*, O S will be a rotating vector, and therefore its projection O S_2 on the vertical axis will be an alternating vector. We thus arrive at the following proposition, which is of very great importance:

The rate of change of an alternating vector of amplitude A and period $\frac{2\pi}{p}$ *(Art. 17) is represented by another alternating vector of the same period, and of amplitude p A, this vector being* $\frac{\pi}{2}$ *(one right angle) in advance of the given vector as regards phase.*

Thus, if we have an alternating vector

$$A \sin p t,$$

its rate of change is represented by the alternating vector,

$$p A \sin \left(p t + \frac{\pi}{2}\right).$$

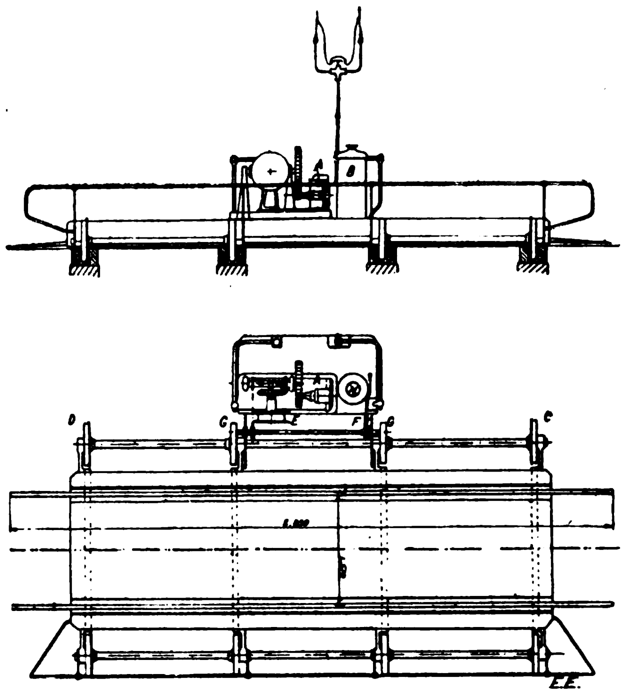
This result may otherwise be expressed thus: the rate of change of a given sine function is represented by another sine function, which is one-quarter of a period in advance of the given function.

In concluding this introductory part of our subject it may be well once more to insist on the extreme importance of the propositions which have just been established. Unless the student has thoroughly mastered them and acquired a clear understanding of what is meant by the *rate of change* of a varying quantity, he cannot hope to make much progress in the study of the principles which underlie alternate-current working.

(To be continued.)

A TRAVELLING PLATFORM FOR RAILWAY WORK.*

The Administration of State Railways at Saintes have just made an interesting application of electricity to the working of surface travellers for shifting railway carriages and wagons in the erecting shop. The traveller runs on small roller wheels, and no pit is necessary. A 3·044-kilowatt motor for 900 revolutions (A, Figs. 1 and 2) is geared by a toothed wheel and pinion to a horizontal axle.



FIGS. 1 AND 2.

This drives by bevel gear a vertical shaft carrying a windlass for hauling on the wagons and also gearing with the rollers, G (see Fig. 2), of the traveller. The current from a dynamo at the works generating station is taken to the motor and back by two overhead wires with rubbing trolleys. The voltage is 110. Carbon brushes are used on the motor without any lead, so that reversal of the direction of travel is obtained by changing the direction of the armature current, and speed regulation is obtained by similar means. The rate of travel when empty is 34 metres (37 yards) per minute, and with a load of 15 tons, 27 metres (29¼ yards). The maximum

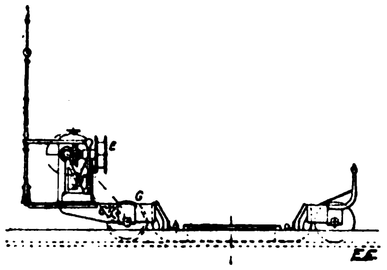


FIG. 3.

speed for hauling the carriages up to the traveller is 75 metres (over 81 yards) per minute. The electrical part of the work has been done by the Société des anciens établissements Cail, and five of the apparatus have been ordered. The cost of each, for the mechanical and electrical part only, is 3,500fr. (about £140), but railwork and adjustment and locking apparatus bring this up to a total of 4,300fr. (£172). At Saintes the current for working is conveyed a distance of 434 metres (470 yards). It is stated that the apparatus has given great satisfaction in use. The starts and stoppages are made with ease and accuracy, and only two men are required for working—one at the motor and one to couple the carriages.

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XVI. of new series of "The Electrical Engineer" *can had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

ALTERNATE-CURRENT MOTORS.

The need of a good alternate-current motor for use on the public supply mains has been often referred to in our columns. We have felt that the motors supplied by the Continental makers have not given complete satisfaction either to the consumer or to the central-station engineer. The requirements of the consumer in many respects are antagonistic to the comfort of the central-station engineer. Thus the consumer may require a motor with a good starting torque, and while the engineer is only too pleased to fill in the great depressions in his load curve, he objects to the pressure on his mains being upset whenever a motor is switched on. The aim of the Continental makers of single-phase alternate-current motors has been to prevent such disturbance by suitable starting gear. Again, the user of an electric motor demands that it shall have a high efficiency, and if his meter only registers watts the power factor of the motor does not affect him. This power factor is of great importance to the central-station engineer, as the drop of voltage due to current and self-induction effects in the mains is largely increased by a decrease in the power factor. We are exceedingly glad to see that the design and manufacture of motors to work on alternate-current systems is being taken up in our own country. Mr. Langdon Davies has, we believe, devoted much care and original thought to the subject, and may be congratulated on the results of his efforts. We were privileged to see some of his motors at work recently. In the limited time then at our disposal we had every convenience given us for examining their qualities. From the rough tests thus made, we gather that a good motor has been produced of which its designer may be justly proud, but we disagree with the expert report now being used to recommend this motor to the public. In this report, which we print in full in the present issue, an efficiency of over 96 per cent. is claimed for a three-quarter horse-power motor. Such an abnormally high result is quite sufficient to show that some fault must exist in the testing apparatus. The electrical and magnetic losses in an alternate-current motor can be fairly compared with those in a transformer. Any difference would certainly be in favour of the latter. A transformer of three and a quarter horse-power having over 90 per cent. efficiency at half-load is rarely, if ever, met with in practice. Yet for this motor, in which bearing friction and mechanical losses are also found, the expert in question does not hesitate to claim such a result. It would be absurd to attempt to point out where the flaw in the test has occurred, but we would suggest that the readings of the wattmeter might be improved upon. The true watts calculated from these readings are given in four significant figures, while the readings themselves appear to have at the most an accuracy of 5 per cent. This remarkable wattmeter also shows that when the brake is loaded with two pounds, the addition of another pound, while it increases the brake horse-power, it decreases the watts given to the motor. The same wonderful absence of fractions can be seen to a smaller extent in the ampere readings. Half a

Digitized by Google

division in fifteen is the very least fraction recorded in the set of readings, while readings for the current under practically constant load vary by as much as 7 per cent. Assuming these instruments to be correctly calibrated, the recorded readings might lead one to expect such discrepancies as are found between the different efficiencies with a given load on the brake. This does not account, however, for the high efficiency prevailing throughout. Leaving the table of observations, and coming to the report itself, we find a general commendation of the motors running throughout, and accompanied by a lack of facts. Thus we are assured that in starting torque the motor is far above all its rivals, but we look in vain for any hint of the fact that this starting torque is only obtained by an abnormally large current. That the central-station engineers would debar the use of a motor on their systems which took more than five times its normal current when starting is extremely probable. Yet we find no hint that to obtain one-quarter of the full-load torque—not one-half, as stated in error in the report—the current required would exceed the above limit. Again, although perhaps it is too small a point to be worthy of the expert's notice, we find no comparative brake test with the common Prony brake, and the general public is not told that the Raffard brake puts a purely torsional strain on the motor shaft. These motors, with the frequency common in English stations, give too high a speed for direct coupling to anything but very small fans, and generally will drive by belts. The working conditions will thus give a side strain on the bearing, which at the high speed will materially alter the efficiency. The general conclusion of the expert at the commencement of his report states that the motors are worked on the same principle as the two and three phase motors, which gives to them the advantages of such polyphase systems. He adds, "it has long been known that these advantages could be in degree realised by the device known as 'splitting the phase' of the current, but this device has never hitherto been used to the best advantage. As a result, the motors are of higher efficiency, and start on load more readily than any other alternate-current motors of equal output." These statements are most misleading. The phase-splitting device is only used in starting, and its effect increases the starting current to a prohibitive amount, so that the resistance method of phase splitting has been generally abandoned. The so-called "advantageous phase splitting," not being in use when the motor is loaded, cannot influence the efficiency, and yet the expert does not hesitate to publish figures showing efficiency higher than any obtained with multiphase motors, and 30 per cent. higher than those from any single-phase motor of the same output previously on the market. That such an enormous stride can be made off-hand is most highly improbable in the present advanced state of the industry. We would go as far as to say that it is a physical impossibility, with the present material at our command, to make a single-phase motor having the efficiencies claimed. We regret to have to call attention to this report so strongly, but its wide distribution and general acceptance among the technical and non-technical Press leaves us no option.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

STREET TRAFFIC AND MOTOR VEHICLES.

SIR,—The congested state of our streets frequently attracts attention, and has lately been commented upon in several of the daily papers. It is a well-known fact that the traffic in the City streets is becoming every year more difficult to cope with, and that some further means than have been devised are necessary for its relief is evident.

I am of opinion, with others who have studied this subject, that the introduction of mechanically-propelled vehicles will greatly reduce the pressure in our streets. It cannot, of course, be expected that this mode of locomotion will be adopted immediately. It will be many years before its use becomes general, but the due appreciation of the benefits to follow will certainly accelerate the desired result.

The mechanical vehicle has the following advantages over that drawn by horses: it can turn the sharpest corner with ease; it can be started and stopped in shorter time and distance, and can turn in the street without blocking the traffic, owing to less space being required; it is more perfectly under control, and can be steered more accurately than a horse carriage. The straining efforts of horses to start a heavy load when the roadway is at all slippery are often painful to passers-by, and fallen horses daily cause confusion in our streets.

The control of the traffic will be far simpler when motor vehicles are in every-day use, and the dangers in the streets will be considerably lessened. Should a motor carriage be disabled, it could be withdrawn from the main traffic with far greater ease than is the case with a fallen horse. I do not mean to infer by these remarks that horses will ever be entirely dispensed with, but we shall not see so many of the poor and overworked horses now so common.

I may suggest that an examination might be instituted, and an expert appointed to grant certificates to those qualified to drive motor vehicles; these certificates to be carried and produced by the driver whenever required by the police.—Yours, etc.,

F. J. WARDEN-STEVENS.

NORTHAMPTON INSTITUTE.

Through the courtesy of the principal, Mr. R. Mullineux Walmsley, we had on Wednesday an opportunity of seeing the buildings of the Northampton Institute in their present state. Mr. Walmsley kindly explained to us the history of the scheme for the building and equipment of this new teaching and recreative institute in Clerkenwell. The institute forms a part of the City polytechnic scheme, which includes in its range the Birkbeck Institute and the City of London College. Both these institutions are largely connected with the South Kensington system of education and also with the preparation of students for the London degrees. It was therefore laid down as a *sine quâ non* that the Northampton Institute should not encroach upon this work, hence the courses of instruction given there under Mr. Walmsley's able superintendence will be of a purely technical character. There is also a well-arranged social and recreative side to the institute, which will be highly appreciated in the district. The part of the building devoted to this purpose was informally opened on Saturday last. The portion of the building devoted to educational work has been delayed owing to some difficulty in obtaining possession of the whole of the site.

The land upon which the institution is to be built was given by the Marquis of Northampton, and consists of about 1¼ acres. The value of the munificent gift is estimated at something like £30,000. The funds for the building were provided by the City Parochial Charity, assisted by

Digitized by Google

the Skinners' Company and the Saddlers' Company, the first named body provided the bulk of the money, while the Skinners' Company contributed £5,000. The institute has been further started with a handsome endowment fund, providing about £5,000 per annum. Of this amount the major part has been provided by the City Charities, while the Skinners' Company have guaranteed £1,000 per annum and the Saddlers' Company have handed over to the institute the proceeds of the Ritchen Charities, which are estimated to realise about £500 per annum. The governors of the institute consist of representatives of the above donors, and they have power to choose a certain number of additional members to co-operate with them. The County Council will also be represented in time, when grants are received from it.

Mr. Walmsley intends to organise the educational scheme so as to be in touch with the numerous industries of the Clerkenwell district. Hence watchmaking will take a very considerable place in the programme, and leading arts connected with the design of watches and clocks will be carefully provided for. In the arts department such subjects as engraving and setting of precious stones, etc., will be included in the usual courses. In the engineering and physical department a general knowledge will be given, the aim of the institute being rather to supplement the knowledge of those engaged in industry than to turn out artisans specially skilled in any one branch of work. In this way Mr. Walmsley hopes to combat the tendency to convert men into machines, which is the result of the modern system of extreme sub-division of labour. We were informed that previous efforts in the technical training in watchmaking elsewhere had not been so successful owing to the opposite aim being followed. We agreed entirely with Mr. Walmsley when he stated that no institute could hope to give the training derived from daily work at the trade, and that the subject of technical education should be rather to train men to use their brains when working. The buildings as yet are hardly in sufficiently advanced stage to be described, but the parts completed to the designs of the architect, Mr. E. W. Mountford, show great attention to the convenience and safety of the members. The large hall, capable of holding comfortably some 1,500 people, is practically completed. The exits from it have been most carefully arranged so that the audience can leave the hall without danger should a panic arise. The gymnasium is also completed and equipped. This branch is under the superintendence of Prof. Oberholyer, of the German Gymnasium. The part of the institution devoted to teaching is, as stated above, in too backward a state to enable Mr. Walmsley to complete his arrangements for its outfit. Some rough idea of the large machinery can, however, be obtained. Two boilers of equal steaming capacity are being erected—one of the water-tube type, and the other a Lancashire. Complete arrangements for feed-heating, economisers, and superheaters will be added, so that comparative tests can be made with and without these economic adjuncts. In the engine-room a Willans and Robinson 100-h.p. engine will be erected, and coupled direct to a 75-h.p. Castle dynamo, by Messrs. J. H. Holmes and Co. Mr. Walmsley hopes to add a horizontal engine of the same power driving by ropes another dynamo. In this way a large amount of combined tests can be carried out.

We hope at a later date to be able to give a full detailed account of this institution.

ELECTRIC TRACTION.

Among the papers read at the annual meeting of the Association of Municipal and County Engineers at Brighton last week was one by Mr. R St. George Moore on this subject, which we give herewith. The paper was taken on Friday morning, and a very interesting discussion followed. In our issue of November 8 last we published illustrations of the Brighton and Rottingdean electric railway (which was referred to by Mr. Moore) showing sections of track, details of trolley pole connections, and a side elevation of the car.

Electric Traction: A Review of its Application and a Comparison with other Methods.

BY R. ST. GEORGE MOORE, M.I.C.E.

A civil engineer acting either for a corporation or in general practice has frequently to advise on matters about which it is an absolute impossibility for him to be conversant with all the details. For instance, in the preparation of waterworks scheme he has to decide upon the type of pumping machinery to be adopted; whereas it would be unwise for him to attempt to design the machinery, knowing as we do that all machinery such as marine engines, pumping engines, etc., have been brought to their present condition by the makers of the various types gradually introducing improvement upon improvement. The same case will apply to traction. It would, in the first instance, probably devolve upon the civil engineer to decide whether electrical or some other method of traction should be adopted, his knowledge of the nature of the traffic to be carried, the nature of the permanent way, the grades and curves being essential to come to a proper decision. When this decision has been arrived at, then the detail ought to be put into the hands of one of those who have made the method of traction selected their speciality. The author's object, therefore, in this paper is to consider electric traction, not from an electrical engineer's point of view, but from a civil engineer's, and to describe a few of the leading and most instructive examples and analyse their merits or demerits. The following lines have been selected for description as illustrating the distinctive features of electric traction : (1) the Brighton Electric Railway; (2) street railways; (3) the Liverpool Overhead; (4) Brighton and Rottingdean Sea-shore Electric Tramroad.

Brighton Electric Railway.—The Brighton Electric Railway is described first, as being the pioneer electric railway in the United Kingdom and Ireland, having been opened by the Mayor of Brighton on August 2, 1883, the next being that at the Giant's Causeway in Ireland, which was opened in November of the same year. Further, because it is one of the best exponents of the application of electric traction on a small scale. The line commences opposite to the entrance to the Aquarium, and runs for a distance of about a quarter of a mile principally on wooden tressel work placed on the outside of the sea-wall, so that in rough weather the main frame and working portions are open to the salt-water spray, which would be a serious drawback to any other method of traction. The line passes under the Chain Pier and along the top of the beach to the terminus at Paston-place, a total distance of about one mile, the steepest gradient being on the east side of the Chain Pier, which is 1 in 14. The electricity is supplied from a generating station at Paston-place, the prime mover being a 20 nominal horse-power gas-engine. The power is conveyed from the central station to the cars by a third rail. The cars weigh complete with motor and gear, but exclusive of passengers, 1¼ and 1¾ tons; and when fully loaded, 3¼ and 4 tons. With the above plant four cars can be kept running at the same time at (if required) 14 miles per hour, at a total average cost of 4d. per car mile. This includes depreciation and repairs, but not interest on capital.

Street Railways or Tramways.—The principal application of electric traction has been its substitution for horse traction on street railways or tramways, as exemplified by those in Dublin, Hamburg, Brussels, and Bristol, and a large number of other towns, one company in America having a total length of road of 272 miles and 1,705 motorcars. The initial difficulty of the application of electricity to tramways was the distribution of the motive power. Two methods have at various times and places been adopted—first, the conductor in a conduit; second, the overhead wire or trolley system. The first consists of a copper or iron conductor carried on insulators, as in the third-rail system, but placed below the surface of the road and protected by an iron casing with a slot in the top, through which slot contact is formed. This system has never been extensively used. The drawbacks to it are its expense, its being liable to get filled with water and mud, and the width of the slot at points and crossings being a great disadvantage to wheel traffic. The system which has been most universally adopted, there being about 10,000 miles working with this system in America and 1,000 miles in Europe, consists of an overhead conductor, generally a copper wire, suspended on poles similar to telegraph wires, but of course very much heavier. In England, considerable objection is raised to this system on account of the danger to the traffic from a falling wire and the unsightliness of the poles. The author considers that the value of these objections has been considerably over-estimated—the danger from the wire being reduced to a minimum by care and attention, and the poles now being made an ornament rather than an eyesore. [By the kindness of Mr. Philip Dawson, illustrations of the poles used at Dublin and Bristol, together with several specimens of trolleys and insulators, were shown.] The poles illustrated are manufactured in America, English makers not having as yet adopted any good system for making the joints between the varying diameters of the tubing, the adopted test for which

Digitized by Google

s that the pole is to be lifted 6ft. and allowed to fall free, when if any of the joints have telescoped the pole is rejected.

Permanent Way.—If electric traction is adopted in preference to cable or horse traction greater attention must be given to the permanent way, because of the greater weight of a motorcar than an ordinary tramcar, or of one for a cable road, and also because of the motor being a delicate instrument to which violent shocks are detrimental. The Americans are using rails as heavy as 100lb. per yard, with welded instead of fishplate joints, but when there is a good foundation the author is of opinion a lighter section is admissible. Steep gradients are no detriment to electric traction by motorcars. In the United States they have been made to work up to 1 in 7. If a locomotive is employed the dead-weight has to be carried to produce adhesion, whereas with the motorcar the car and passengers are the weight-producing adhesion. The Dublin electric tramway system, which was opened on May 16 last, commences near the centre of Dublin and runs to Dalkey, a distance of 7¾ miles. The heaviest gradient is 1 in 16. The rails are of the ordinary girder type, weighing 76lb. per yard, and the gauge is 5ft. 2 3-16in. The trolley system has been adopted; the overhead wire conductor is carried for the greater portion of the distance by means of span wires stretched across the streets; a small portion is carried by the double-bracket poles shown. The peculiarity of this installation is that electricity of various pressures is generated at the central station at Ballsbridge. The lower pressure is conveyed direct to the conductor, from which the car draws its supply, and the higher to one or other of the two sub-stations, where it is reduced in pressure and supplied to another section of the line. The sub-stations are at Blackrock and Dalkey, the object of this being to save loss by leakage and cost in the conductor; a small conductor being capable of conveying the same power at a high pressure as a larger one can at a low pressure, also to enable them to maintain the pressure required by the Board of Trade in the return current.

The Liverpool Overhead Railway.—This railway runs for a distance of about seven miles along the inside of the docks at Liverpool; it is carried for nearly the whole of its length on an iron viaduct. There are 15 stations, averaging about 900 yards apart. Each train consists of two motor carriages, seating together 114 passengers, and weighing, including passengers, 38 to 40 tons. The train service is every five minutes, and there are 12 trains either starting, travelling, stopping, or at rest, all being actuated from the prime mover situated in the central generating station. There is one short gradient of 1 in 40, and the sharpest curve is seven chains. Mr. Parker, in his paper read before the Institution of Civil Engineers, gives the cost to be between 3·441d. and 4·075d. per car mile, with about 40,000 car miles per month. This line and its electrical equipment is very fully described in the papers by Messrs. Greathead, Fox, and Parker, vol. cxvii. of the *Minutes of Proceedings* of the Institution of Civil Engineers.

Brighton and Rottingdean Seashore Electric Tramroad.—This line is one of the latest and most peculiar applications of electric traction. Before describing the reasons for adopting electric traction it will be necessary to give a brief description of the line. This line is situated on the foreshore entirely between high and low water, and extends from the Paston-place groyne within the borough of Brighton to Rottingdean—a distance of two miles seven furlongs. At high water of spring tides, at the deepest portion of the line, the car will run in 15ft. of water—that is to say, the rail-level will be 15ft. below water-level. The permanent way consists of four lines of 52lb. steel flange rails, specially rolled with an additional width of flange and thickness of web to compensate for the corrosion which will take place, and thereby equalise the life of these portions with the rail-head, the life of which, it is anticipated, will be considerable owing to the comparatively small amount of traffic to which it will be subjected. The rails are laid in pairs to a gauge of 2ft. 8½in., and to a total gauge between the outer rails of 18ft. The sleepers of ordinary railway practice are substituted by concrete blocks and large cast-iron chairs, according to the nature of the ground. Between the rails and the cast-iron chairs and the concrete blocks oak cushions are fixed. Where concrete blocks are used mortises are cut so as to be at least 6in. into the solid chalk, and a box framed round it of the height required, and the block formed by filling the box with concrete. Although some portion of the line has been completed two winters, after the concrete has once had time to set no damage has been done to the blocks, either by the sea or frost. As may readily be understood, a large amount of trouble was caused by rough weather damaging the blocks in their green state. The precedent for the use of concrete sleepers was the favourable results obtained for slow traffic by the Würtemberg States Railway prior to the general adoption in Germany of steel or iron sleepers. The cast-iron chairs are similarly fixed, with the exception that the mortises are deeper, and where the chair stands more than 2ft. out of the ground a concrete plinth is built round it. The rails and oak cushions are fastened to the concrete blocks by two bolts built into the block during construction. The ruling grade is 1 in 300, and 40-chain curves (with the exception of one very short piece of curve near the Paston-place station) have been adopted. The stations at Paston-place and Rottingdean are small piers or jetties constructed in iron, with a deck level with the deck of the car, or about 23ft. above rail-level.

The car is carried on 16 33in. wheels in four bogies, two of which occupy each line of road, and are held in position by a strong steel tube framing. On each bogie stands a main steel tube column, from which spring the arched girders supporting the deck. The level of the deck is 23ft. above rail-level, and 46ft. long by 22ft. wide. A deck-house, for shelter in wet weather, 25ft. 3in. long and 12ft. 6in. wide, with a promenade deck, is provided. The car when fully loaded will weigh about 50 tons, and it would require a wind pressure nearly equal to three times that of a hurricane, or 134·4lb. per square foot of exposed surface, to create an equilibrium of forces—that is to say, if the inner line of rail is taken as the fulcrum and the weight of the car as acting vertically through its centre of gravity, we get $9 \times 60 \times 2{,}240$ units of resistance, taking the centre of pressure at 25·0 above rail, the area exposed 300 square feet, and x the lbs. per square foot, we get $x \times 25 \times 300 = 9 \times 50 \times 2{,}240 : x = 134{\cdot}4$. This force would only produce an equilibrium; the force therefore required to lift the car round the inner rail as a turning centre and turn it over would, of course, be very much larger. The margin of stability of the car from overturning from an impediment in the permanent way is very great.

The electrical generating station is at Rottingdean, and the current is conveyed to the car by an overhead copper wire and trolley pole. The motors are placed on the main deck of the car, and are connected with the driving wheels by shafting down two of the steel tube legs and bevel gearing. On the rear bogies powerful hand-brakes are fixed. The prime mover is one of Sissons's compound high-speed surface-condensing engines, indicating 110 h.p., driving a direct-coupled dynamo. The two motors have an effective brake horse-power of 30 each, and it is anticipated that they will drive the car at six miles per hour. The selection of a motive power for this line was comparatively easy; there were practically only two to choose between (1) steam and (2) electricity. Steam, of course, could have been adopted, but the heat from the boiler was looked upon as a disadvantage, therefore electricity was decided upon and adopted.

Mr. Volk and the author, who are jointly responsible for these works, trust they will have the pleasure of showing such portion of the work as is completed to the members of the association. Electricity has established its own distinctive position among tractive powers—viz., for short-distance frequent services, such as street railways, because, when there are a large number of cars on a system worked from a central station they become like the properly-balanced reciprocating parts of a machine. Take, for instance, a system worked with 20 motorcars, with stopping places every 1,000 yards, each car requiring x horse-power for the first 50 yards, some proportion of x for 850 yards, say, for simplicity, $\frac{x}{2}$, and 0 for the remaining 100 yards while stopping, and 0 while at rest. Then, assuming that the traffic could be so arranged that five cars were starting, five making the centre portion of the run, five stopping and five at rest, we get $(x \times 5) + \left(\frac{x}{2} \times 5\right) + (0 \times 5) + (0 \times 5) = 7\frac{1}{2}\,x$, instead of the 20 x which would be required if each car had its own engine. Or take it that five cars are starting, 10 running and five either stopping or at rest, even then we get 10 x instead of 20 x. Of course, in this reasoning no account is taken of the greater efficiency of the large prime mover in a central station or the loss in the conduction. Up to the present it has not been brought within the limits of practical competition with steam for long-distance heavy traffic, although considerable experiments have been made in that direction. The difficulty of selection, therefore, occurs when the traffic to be dealt with is either very light and seldom, or heavy and for considerable distances, and for these cases no general rules can be laid down: they have each to be treated on their own respective merits. Take as an illustration the very extreme case of a street railway installation for a small town, where the total length of the line would be two miles, and where a half-hour service would suffice for the traffic. Two cars start one from each end at the same time and arrive at their destination 20 minutes after starting: therefore, for 33 per cent. of the time the prime mover is running it is doing no work.

The cable tramway and electrical tramway have one very distinctive feature in common—namely, the central generating station—the difference being the form in which the power is transmitted from the prime mover to the car. The two points, therefore, to be considered are the prime cost of the road and efficiency of the transmitter. The cost of the installation of a cable road is very much greater than that for an electrical trolley line, as may readily be understood when a comparison is made between the cost of the pole and wire and the under-

Digitized by Google

ground conduit furnished with cable and sheaves, even after allowing for the cost of the dynamos and motors. The efficiency is also less—that is to say, that with a given horse-power at the generating station, the effective horse-power available in the axle would, with the cable system, be just half that with an electrical system. Further, the electrical system is capable of far greater extension without additional generating stations than the cable system, as the length of a cable is limited, and that of an electric system (by the introduction of transformer stations) is, within reason, practically unlimited.

In conclusion, the author looks forward to the time when the road motorcar shall have been brought to perfection, whether it be driven by steam, oil, electricity, or by some power the discovery of which is still in the womb of the future. There is no doubt the advantages to civilisation will be large, but, to a great extent, an unknown quantity. Of one thing we may rest assured—viz., that the increased cleanliness of the streets in large towns will enormously add to the salubrity. What would the general public say if engineers suggested a tractive force which would deposit on the roads the same amount of noxious matter as results from horse traction. A further advantage will be the decrease in the amount of foodstuffs for which we shall be dependent on foreign countries, for instance. The horses in London would alone consume more than the produce of a million acres of ground. The saving of the space occupied by the horses, which equals at least 50 per cent. of the total area occupied by the traffic, would be sufficient to relieve many heavy congested districts, even in London.

After the reading of the paper an adjournment was made to the Brighton central electricity station in North-road, where the important extensions, which we illustrated last week, and which are approaching completion, were inspected by the members of the association. We understand the extension and the old buildings when full will contain about 12,000 h.p. of machinery, which it is expected will suffice for the electrical requirements of Brighton for a few years. The designs have been made by Mr. May, the borough engineer, and the machinery is under the control of Mr. Wright, the borough electrical engineer. The structural work is being carried out by Messrs. W. A. Field and Co., contractors, of Brighton. It surprised some of the members to find that Mr. Wright was going to drive all his subsidiary machinery by means of electric motors, but he pointed out that small engines were not economical, and that if he generated his steam by means of a 2,000-h.p. plant, with a double transformation he could get his work done more economically even with that double transformation than if he drove the subsidiary machinery direct by means of small engines.

PRECAUTIONS NECESSARY IN THE USE OF ELECTRICITY IN COAL-MINES.*

BY H. W. RAVENSHAW.

It is proposed in this paper to offer a few suggestions, the carrying out of which may serve to minimise the risk both from shock and fire.

Shocks.—A very unpleasant shock can be obtained from a 600-volt circuit, even on dry ground, and the results might be very serious to anyone who was standing on a wet floor or in water. A shock may also cause a man to fall without directly injuring him, and for this reason gear-wheels and other moving parts should be well guarded in the neighbourhood of any switches, resistances, or motors, which might have to be handled during the running of the machinery. All parts of the electric circuit should be covered, so that it is not possible to touch them without deliberately taking off the protecting covers, and the metal cases of switches and junction-boxes should always be connected permanently to earth by a stout wire, either through the tramroad rails or to water-pipes in the vicinity. Motor bedplates should also be well earthed, especially if the machines be fixed on timber foundations. An instance has come before the author where a shock was obtained from a hauling rope, the hauling engine having been fixed to heavy timbers in a very dry pit, and an accidental contact having occurred between the motor and the frame of the hauling engine. Where parts, such as brushes, have to be handled while the circuit is alive, a sound dry timber floor, with perhaps a rubber mat and a wooden handrail for the man to steady himself by, are the best protection. Indiarubber gloves are most uncomfortable and clumsy; they are liable to be pierced by small chips of metal, in which case they are worse than useless, and, except in awkward situations, they are not to be recommended. Even with a low voltage it is possible to obtain a very severe shock, owing to the high pressure which is momentarily obtained in breaking the circuit of an electromagnet. The author cannot give any instance where loss of life has been traced to this form of shock, but the experience of anyone who has accidentally broken the circuit of even a small magnet, and whose body has remained as a shunt to the break, is one to be remembered for a lifetime. Great care should therefore be taken in handling the wires connected to the field magnets.

Main Conductors – One of the principal characteristics of electric power is the enormous amount of heat which can be concentrated into a small space, and consequently the high temperature which results. These conditions can be obtained either by an arc being formed, as in the case of a broken wire, when a considerable amount of energy is expended in the air gap; or by a short-circuit, where practically the whole of the power which can be generated is concentrated in a comparatively small part of the system. The result of a short-circuit, extending as it does to the generating station, is easy to deal with, and fuses or other automatic devices can be employed to break the circuit before much damage is done. In certain cases, however, a partial short-circuit may cause great heating, although the current due to the reduced resistance may not be sufficient to blow the fuses at the generating station. It is imperative that the very best materials and workmanship be put into the cables. The difference in cost between the very best and the cheapest is so small that it is never advisable to even consider the desirability of using a cheap cable. Where the shaft is wet, the cable should be run in cast or wrought iron pipes having joints and junction-boxes made thoroughly water-tight. These protecting pipes should be carried as far into the mine as is necessary to get clear of the water. Where, however, there is no water, armoured cables may be used, care, however, being taken that they cannot be readily damaged by any accident to the cage. The usual method of carrying the cables from the bottom of the shaft to the motor is to suspend them from the timbers by means of insulators. In fixing them in this way there is great danger of the cables being damaged either by falls of the roof, breaking of the timbers, or by run-away wagons. In most cases, however, the cost of protecting the cables would be so great that this simple method is to be preferred, especially as they are accessible for inspection and repair. Several schemes have been suggested and some have been tried for preventing the occurrence of a spark or flame on the breakage of a cable. None of these arrangements has been generally adopted, and it is very doubtful whether any device can be relied on whose action must necessarily depend on the accurate adjustment of comparatively delicate apparatus. Personally, the author is very much in favour of the use of concentric cables, the external conductor being connected to earth at frequent intervals if not continuously. There are some draw-backs to this arrangement, especially in the switches and motors, but these can be guarded against, and the risk from fire in case of damage to the cables is enormously reduced. In the concentric cable, one conductor is thoroughly well insulated, and the other is stranded over the outside of this insulation. In some cases the outer conductor is used for the protection of the cable, no other insulation being used on the outside. It is, however, advisable to make the cable perfectly water-tight by means of leaden covering, and again to protect it with iron armouring. In damp places it may be necessary to cover the armouring with insulating material to prevent corrosion from electrolysis. A number of installations have been fitted up on this system, the outer or return wire being uninsulated or connected to earth. This, of course, has the disadvantage that the chance of breakdown from defective insulation is doubled; in fact, on the cable being damaged a short-circuit will be almost certain to occur on the particular section affected. This drawback is, however, really counter-balanced by the fact that defects at once show themselves, as the safety fuse breaks the connection in a part of the mine where the resulting spark can do no harm. It does not appear possible for the concentric cable to be broken without the inner wire coming in contact with the outer, causing a short-circuit, and cutting off the current at the fuses before the wires are severed, and preventing a big flash at a place where a fall of roof may have liberated gas.

Junction-Boxes.—Branches and joints should always be made in cast-iron junction-boxes in order that soldering may be avoided. These boxes should contain good solid terminals mounted on slate or porcelain, the opposite poles being well separated from each other. The cables should be taken through stuffing-boxes, and the wire so fixed to the terminals that it is impossible for the cables to be drawn out accidentally. The boxes must, of course, be watertight, the covers having faced joints so that loose packing is not required, as this always gets displaced in time.

Switches.—Where a branch occurs, a switch should be fixed in order that the circuit can be broken for testing or in case of accident. With concentric wiring a single-pole switch is only required, which will break the circuit of the inner wire. In

* Abstract of paper read before the Federated Institution of Mining Engineers.

Digitized by Google

double wiring, however, both poles should be provided with switches. Switches must always be so made that there is no fear of an arc being started on breaking the circuit, and it is most important that with double-pole switches the parts of opposite potential operate in quite separate compartments, having a division of slate or porcelain between them. The break should be at least 6in. long on each pole. Switch-boxes should be lined with slate to prevent an arc being started on to the metal case. It should be absolutely certain that, when the switch is turned off, the circuit is entirely broken. It is difficult to conceive a more unpleasant predicament than for a switch to take charge and start an arc on its own account instead of breaking the circuit. This has actually occurred in practice where the switches have been designed so as to be neat and compact and efficiency of working has been overlooked. It is quite easy to make a switch which will always perform its functions without risk of failure, and no expense should be spared in this part of the plant. Where switches are enclosed in metal cases, they must be perfectly airtight. Stuffing-boxes for the cables are always liable to leak, and it is advisable where there is gas to have a separate box carrying the terminals, into which the cables can be brought, the connections to the inside of the switch being sealed up with bitumen or similar material. Resistance frames in connection with starting and regulating switches are always liable to cause contact with the earth. When porcelain insulators are used, the frame to which they are fixed should also be insulated, so that in case of a broken insulator the wire which it has supported will not make contact to earth. Wire coils are often used for resistances, and are usually flexible and liable to knock against each other or against their supports. They should be so spaced that it is impossible for them to touch surrounding objects, as a more or less dangerous spark might be caused by adjacent coils coming in contact. All resistances should be amply large enough to carry all the current that it is possible to put through them without over-heating. In some cases, as on coal-cutters, it would be impossible to fit resistances which would be capable of carrying the current continuously. In this case the switch must never be left in an intermediate position—in fact, it should be made so that it is impossible to leave it in any position except wholly on or wholly off. Water resistances in which the circuit is broken between the surface of water or a weak alkaline solution, and a metal or carbon contact, are very suitable for starting motors gently, as they can be made so that there is no spark between the contact and the surface of the water. As, however, the water is decomposed, these switches should not be enclosed in such a way that the explosive gases generated can accumulate. This form of switch is very simple, and is not liable to get out of order.

Motors.—Although the electric motor is now fairly well standardised, it is very important that the type of machine chosen is suitable for the work it will have to do. Where a large number of motors are in use on the same installation, it is usual to put down either shunt-wound or compound-wound machines which work in parallel. Very fair regulation can thus be obtained, and if the cables be properly proportioned the starting or stopping of any one motor should not affect the speed of any other. Where, however, only one motor is used it is advisable to have both motor and dynamo series wound. If these machines be properly designed, the speed regulation of the motor, given a regular speed of the dynamo, will be good, and this combination has the great advantage that when the motor is switched off the dynamo gives no volts and takes little or no power. Series motors have in many cases been used in parallel with other machines for driving pumps. These work well so long as the load is constant, but the motor tends to race if the pump loses its water, and it is advisable for this reason to use a compound-wound motor designed so that it will start readily under load, and will not run away when the load is taken off.

Motor Magnets.—With a series motor the field magnets are very simple, having a comparatively small number of turns of thick wire, which are not liable to be broken or to get displaced. Many of the most successful plants both at home and abroad are arranged on this plan, and it is at times advisable, when there are several motors, to provide an independent dynamo for each. This arrangement has also the advantage that the motor starts very steadily and without shock. Shunt-wound and compound-wound motors are formed with thousands of turns of fine wire, and when the coils are connected across a circuit having a pressure of, say, 600 volts, the wires on adjacent layers have a considerable difference of potential between them. This is a source of breakdown, as if the insulation be defective a partial short-circuit will occur which may in time burn through the fine wire. In fact, cases have occurred where an arc has been started in a shunt coil and the wire very badly burnt, if not destroyed. For this reason the wire must be thoroughly well insulated, and adjacent layers separated by an effective insulating material. The breakdown of the insulation between the wire and the frame of the machine is another source of trouble. The author has seen otherwise well-made machines with only a sheet of Willesden paper between the metal former carrying the coil and the wire itself. There should always be at least ¼in. space between the wire and the metal parts of the machine, mahogany or teak being used to separate the winding from the metal former. When the circuit of an electromagnet is broken, a very high pressure is momentarily produced, which will find out any weak places in the insulation, besides causing a bad spark where the circuit is disconnected. With high-tension shunt magnets, the pressure at breaking is enormous. This danger can be avoided, however, by using a switch which will insert a resistance in parallel with the magnet to be broken just before breaking, the resistance being left in parallel so that the magnet coil can discharge itself at its leisure. If the resistance be properly proportioned and wound non-inductively—that is, so that it does not tend to resist a sudden flow of current—the spark at breaking the circuit of a magnet weighing many tons can be reduced to very small dimensions. In certain cases the switches can be so arranged that the magnets are permanently left in parallel with the armature. It is, however, always advisable, with large motors, to use a switch and resistance as above described, as it is usual to excite the magnets of the motor a minute or two before the armature current is turned on. Series magnet coils will also cause sparking at the switch when the motor is cut off, consequently both motor and dynamo should be fitted with a resistance permanently connected in parallel with the series magnet coil. This resistance absorbs very little power and reduces the spark on breaking the circuit to a very small amount. By taking the above-mentioned precautions, the sparking at the switches can be reduced to a mere speck and the danger from breakdown is practically eliminated.

Motor Armatures.—The most important, and unfortunately the most complicated, part of a continuous-current motor is the armature, but although few radical alterations have been made in the last 10 years many details have been improved, and, given good workmanship, an armature should run without repairs for several years. The use of geared wheels has been one of the most fruitful causes of expense, the rapid vibrations transmitted to the armature being certain to eventually destroy the armature. In certain cases where the speed of the armature is below 500 revolutions per minute, and where the construction is particularly good, an armature will run for many months without repairs, but wherever it is feasible belt driving or worm gearing should be used for the first reduction of speed. It is a remarkable fact that in many cases under heavy vibration an armature gives way mechanically while the insulation remains intact. Consequently, the armature and commutator should be fixed to the shaft by the most efficient mechanical means possible. Two forms of armature are commonly used, having respectively the Gramme or the drum winding. In the former the wires pass through the centre of the armature, the iron core being a hollow cylinder supported on gunmetal arms. This type of armature has been in very general use in collieries, it being considered more suitable for high voltage than drum winding. The drum armature has been used a great deal lately and has many advantages which generally outweigh those of the Gramme. The construction of this armature necessitates the winding of wires, having the full voltage between them, side by side, along the periphery, and unless these are well insulated a short-circuit may occur between them. In the Gramme winding, however, there is a much lower voltage between wire and wire, and in small armatures it is possible to repair a burnt-out coil in a comparatively short time. When, however, large armatures are Gramme-wound, the space inside the core for the wire has to be made as small as possible to keep the size of the machine within reasonable limits, and wires having considerable difference of potential between them are packed together inside the armature. In fact, in case of a burnt-out coil, it is almost always necessary to rewind a sixth or a quarter of the armature. In the ordinary wire-wound drum armature there is an accumulation of wires at the end where the various sections cross one another, but during construction it is very easy to insulate these so that there need be no fear of short-circuit. Drum armatures are, however, being made in which the wires are brought round the end of the armature symmetrically, avoiding contact between wires of opposite potential. Apart from a somewhat greater liability to short-circuit, and in some cases less facility for repair, the drum armature has many advantages over the Gramme, some of which are enumerated below. The armature can be made smaller and lighter for the same work. There is much less liability to spark at the commutator. The armature is a good deal cooler, especially in the larger sizes (this is most important where enclosed machines are used), and mechanically the armature can be made stronger, the charcoal-iron plates being keyed direct on to the shaft without the intervention of a gunmetal spider. In the estimation of the author, however, the greatest advantage lies in the fact that on the occurrence of a short-circuit a drum armature stops at once and refuses to turn round. This causes a great rush of current, which blows the fuses and disconnects the circuit at once. As the current is cut off automatically a drum armature is seldom badly burnt, as the time during which the current is flowing through the short-circuit is too short for

Digitized by Google

much damage to be done. With a Gramme winding, however, the armature may continue to revolve for a long time after a short-circuit has occurred, in which case the armature will be badly burnt, and dangerous sparks or flames given off.

Enclosed Motors.—In fiery mines it is usual to enclose the armature or the commutator in gastight covers, so that an accumulation of gas may not be fired by the sparking at the commutator. It has been contended that it is impossible to fire gas from these sparks, but although a good dynamo will run perfectly at the brushes there is always a chance of sparking owing to the brushes chattering, or to a damaged section of the commutator. The author has designed a large number of enclosed motors during the last few years, and, in his opinion, so long as the covers are really well made and the joints are kept perfectly gastight, they will afford ample protection. There is, however, great danger of the covers being taken off or the joints being improperly made, and it is a question whether they are to be relied on. In large motors there is some difficulty in getting sufficient surface to dissipate the heat which is transmitted from the armature to the covers, and water or compressed-air circulation has been used with good results. Where compressed air is available a constant pressure may be kept up inside the covers, which will effectually exclude any gas which may be about. In any case, it is advisable to thoroughly ventilate the chamber in which the motor is placed, and if this be done, it is doubtful whether it is necessary to enclose the armature. The greatest safeguard against accident is, however, good supervision and careful daily testing.

Testing.—It is most important that the insulation of the cables and the motor be tested daily before starting. This can easily be done from the generating engine-room by the use of testing sets which are at present in the market, and is of the utmost importance for the safety and efficiency of the plant.

ALTERNATE-CURRENT MOTOR TESTS.

The following is the report of Prof. Silvanus P. Thompson, F.R.S., on the alternate-current motors of Mr. Walter Langdon Davies to the Alternate-Current Electric Motor Syndicate, Limited:

Gentlemen,—In accordance with your request to test the alternate-current motors of Mr. Langdon Davies and to report upon the same, I beg to hand you the following statement and result of tests:

Motors of two sizes have been submitted to me. They were designed to run upon an ordinary alternate-current supply at 100 volts, the frequency for which they were designed being 83 periods per second. They have been run both in my laboratory at Finsbury and on the supply circuit of the House-to-House Electric Lighting Company. One of them has also been used by me on the circuit of the London Electric Supply Corporation at a lecture at the Royal Institution.

These motors are constructed in accordance with the specification of patent No. 19,364 of 1894, and embody also some of the further improvements covered by specification No. 18,870 of 1895, both of these being the patents of Mr. Walter Langdon Davies.

The principle of these motors may be briefly stated as being that of using a simple alternating current to produce a rotatory magnetic field by a special method which enables the inventor to attain the advantages hitherto only fully realised by the two-phase and three-phase systems of currents. It has long been known that those advantages could be in degree realised by the device known as "splitting the phase" of the current; but this device has never hitherto been used to the best advantage. The two most important features of the new invention are that by proper proportioning of the coils and disposing them in appropriate angular positions on the principles worked out by Mr. Langdon Davies, the phase of the currents can be split and then recombined so as to yield a true revolving magnetic field without having recourse to condensers or liquid resistances. As a result the motors are of higher efficiency and start on load more readily than any other alternate-current motors of equal output.

The motors consist of two essential parts: The outer stationary part, consisting of a substantial ring core, which receives in perforations the windings of the circuits and is held in an outer metal case, which also supports the bearings. The inner revolving part is even more substantial, and consists of a copper structure resembling a small massive squirrel cage embedded in iron core discs, keyed upon a steel shaft. This revolving part has no wires wound upon it, no commutator, no brushes, or other electric connections which might cause a spark, being entirely self-contained and receiving its electric currents purely by induction. In this respect these motors agree with the well-known induction motors used for two-phase and three-phase currents and with some of the earlier single-phase induction motors. The chief improvements are in the stationary part, since it is in this part that the inductive actions are determined which drive the revolving part, and on which the efficiency of the motor mainly depends.

The larger size of motor, denominated the E type, is of ¾ h.p., though the tests show that it will give out nearly 9-10 h.p. It is a tetrapolar machine, weighing 125lb., 8in. long, and 12·5in. high. The inner revolving part is 4⅞in. in diameter, and run at from 2,550 to 2,250 revolutions per minute, according to load. As will be seen from the accompanying tests, the apparent drop in speed from no load to full load was under 12 per cent.; the real drop was less, as the frequency of the supply had fallen toward the end of the tests.

At the time of these tests the frequency of the supply was found to be 85·6 periods per second and the voltage 99·75; but both the frequency and voltage were found to vary slightly from time to time owing to the varying nature of the demands of houses in the neighbourhood on the supply in the public mains.

The power given out by the motor was measured by a Raffard brake adapted to absorb several horse-power. The friction at the bearings of this brake was found to be rather unduly large owing to worn state of the bushes, and a preliminary trial showed that no less than 148 watts, or about 1-5 h.p., was absorbed thereby when the motor was running idle at a speed of 2,365 revolutions per minute. The power measurements made on the brake had therefore to be increased by crediting to them a corresponding allowance in lieu of any more direct measurements of the total output of power.

The accompanying tables of data and curves show that the maximum power developed by this motor was 0·85 of a horse-

Digitized by Google

power, the efficiency at this output being about 91 per cent. At half-load the efficiency was about the same, but rose in between to about 95 per cent. or higher. At one-third load the efficiency was about 75 per cent.

The high efficiency shown by these tests was confirmed by the general absence of noise and smoothness of running, and by the cool state of the machine at end of the tests. There was no undue heating in any part, and the rotating part was quite cool.

To test the capability of the motor for starting on a dead load various weights were hung upon a cord of a thickness slightly exceeding $\frac{1}{4}$in., which was wound around a pulley $2\frac{5}{8}$in. in diameter, and the motor was started against the load so hung upon the pulley. The greatest weight which could thus be applied was $3\frac{1}{4}$lb. In certain position weights exceeding this could be used. Had the test been less direct, involving use of belting or any gear admitting of backlash or slip, the motor would have started against dead loads considerably greater. This load of $3\frac{1}{4}$lb. on a $2\frac{5}{8}$in. pulley represents an initial torque of about four-tenths of one pound-foot. This is about one-half the torque at the maximum output.

The starting of the motor is accomplished in the simplest manner by the turning of a switch provided with two contact points, the first contact being the position for starting, the second contact being the position for running when the motor has got up its proper speed.

The smaller motor, denoted the C type, is a two-pole motor, which runs at about 4,500 revolutions per minute, and yields about 1·6 h.p. It also runs quite cool, and starts on an initial load. Sheet I., annexed hereto, gives the numerical data of the tests of the larger motor.

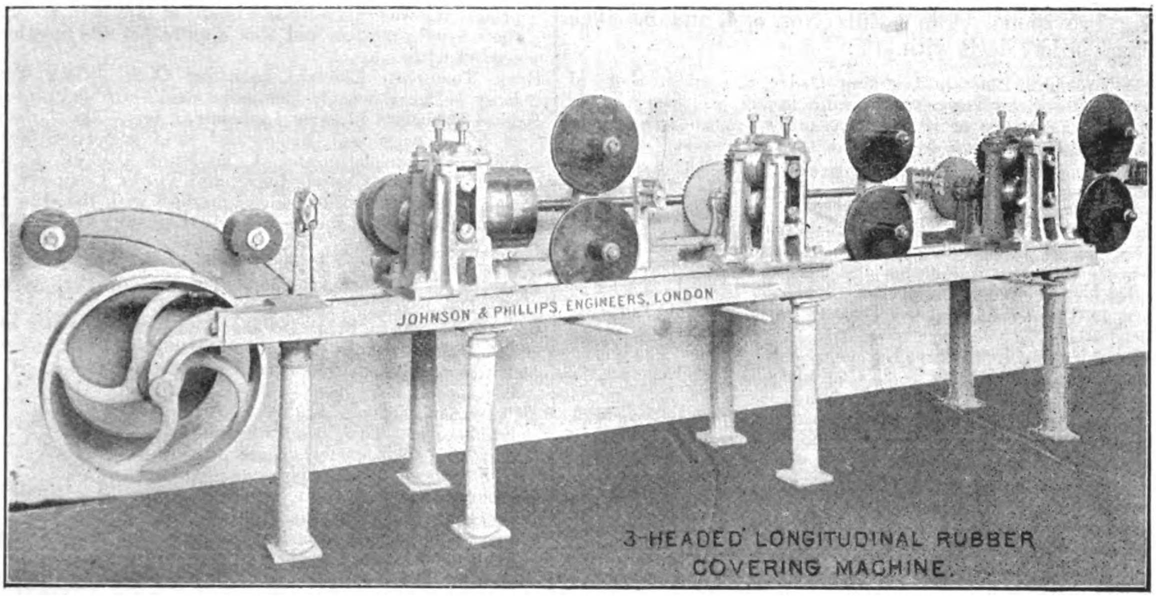
To sum up: these alternate-current motors possess a remarkably high efficiency, and are self-starting to a degree hitherto unattained.

There ought to be a very large demand for motors of this class, since alternate currents are used in half of all the stations recently erected for the public supply of electricity.

May 9, 1896. (Signed) SILVANUS P. THOMPSON.

LONGITUDINAL COVERING MACHINE.

We publish in this issue an illustration of the three-headed longitudinal covering machine manufactured by Messrs. Johnson and Phillips, who are practically the pioneers in this class of

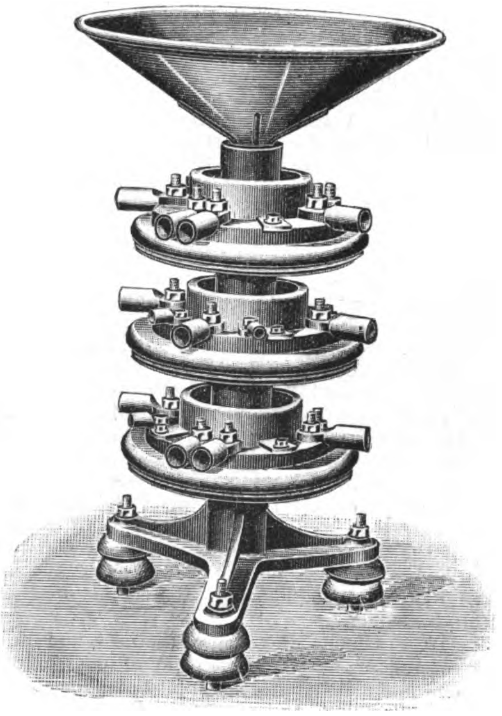


3-HEADED LONGITUDINAL RUBBER COVERING MACHINE.

machinery. This machine is arranged for putting three coats of rubber on simultaneously—viz., one of pure, two of compounded, or three layers of compounded. The many repeat orders the makers have received for it is the best proof of its appreciation in manufacturing circles. For quantity and quality of work produced it is unequalled, being arranged to cover any number of wires up to 12 simultaneously. It is capable of turning out about 30 miles of covered per day without any fault, which is very exceptional with this type of machine. It entirely displaces the old type of machine in which the rubber is squeezed round the wire through dies. We are informed that the insulation obtained by this machine is absolutely perfect, whereas with the other type only very inferior rubber compound could be used, and consequently only very low insulation could be obtained.

THE WORDINGHAM PILLAR DISTRIBUTOR.

Most engineers are agreed that it is desirable to interconnect a distributing network at as many points as possible, in order chiefly to equalise the pressure. If this interconnection is well carried out, it further enables smaller feeders to deal with the constantly shifting area of maximum demand. The great drawback



to such interconnection is the difficulty of localising a fault should one occur, and with a view to providing for this it is essential that all linking points should be capable of rapid disconnection. This is by no means easy to provide for in a neat and convenient manner when there are many cables meeting in one point, say where four streets meet, and the difficulty is very largely increased when the distribution is effected on the five-wire system, since the number of cables is largely augmented. The necessity for some convenient apparatus of high insulation for the purpose named led Mr. C. H. Wordingham, chief engineer to the Manchester Corporation electric works, to devise the apparatus illustrated in this issue, to which he has given the name of "Pillar Distributor."

A central, hollow, cast-iron column standing on three oil insulators is fixed in the junction-box. From this column project at five different levels three cast-iron lugs 120deg. apart, cast in one with the column. Five cast-iron plates, each having three slots separated from one another by 120deg., and three recesses on the underside placed between the slots, are provided. One of these plates is slipped over the pillar, the slots allowing it to pass the lugs until the bottom three lugs are

Digitized by Google

reached. The plate is then turned through an angle till the recesses are opposite the lugs. The plate is then dropped down, and takes a firm seat. On the plate are placed two flat rubber rings, which serve as a bed for a porcelain insulator of the form shown. This insulator is large enough to slip past the cast-iron lugs. Three slate wedges covered with indiarubber strip are placed between the insulator and the pillar, so that the insulator is firmly fixed. A substantial ring of gunmetal is now placed on the insulator; this ring is prevented from slipping about by means of four small brass pieces secured by bolts, and rendered adjustable by means of slots. This ring has studs and tapped holes, which admit of a large number of lugs into which cables are sweated, being affixed to it by means of nuts and bolts. A second cast-iron plate is now slid down the pillar and fixed on the next three lugs from the bottom, and an insulator and ring placed on it as before described. Three more cast-iron plates which, with its insulator and ring, are then fixed on the remaining lugs. A large funnel is slipped on to the top of the pillar. This serves to collect any water that may drip into the junction-box, and so prevent it from falling on the apparatus. The water runs down the funnel through the interior of the column.

The illustration shows the apparatus complete without any cables attached. Such a pillar distributor is capable of dealing with a very large number of cables. Each ring can readily have 6½ square inch cables and six smaller ones attached to it—that is to say, the pillar as a whole will deal with 70 cables. A considerable number of these distributors have been introduced into the Manchester network with the most marked success; indeed, they are being placed at all important points of intersection. It is quite easy to disconnect the five cables which pass down a street in as many minutes, and in case of a fault portions of the network from which a large supply is being taken can be broken with perfect safety. On one occasion as much as 1,700 amperes at 200 volts was successfully disconnected on one of these pillars.

Messrs. W. T. Glover and Co., of Salford, and 39, Victoria-street, Westminster, have the sole right of manufacturing these Wordingham pillar distributors, samples of which may be seen at their works or offices, and also at the Cardiff Exhibition.

ELECTRIC LIGHTING PROVISIONAL ORDERS.

The following gives the House of Commons returns of the memoranda stating the nature of the proposals contained in the provisional orders included in the Electric Lighting Provisional Orders Bills Nos. 3, 4, and 5. The provisional orders dealt with are:

The Bray Township Electric Lighting Order, the undertakers of which are the Bray Township Commissioners, and the area of supply the Township of Bray. The order contains the usual provisions, and mains are to be laid within two years.

Cork Electric Lighting Order, 1896.—The undertakers are the Corporation of Cork, and the area of supply is the City or Borough of Cork.

Liverpool Electric Lighting Order, 1896.—The undertakers are the Corporation of Liverpool. The area of supply is the City of Liverpool, and the order, besides the usual provisions, also provides for the revocation of the Liverpool Electric Lighting Orders, 1891 and 1892, and the Toxteth Park Electric Lighting Order, 1891.

Queenstown Township Electric Lighting Order, 1896.—The undertakers are the Queenstown Town Commissioners, and the area of supply is the Township of Queenstown.

Rathmines and Rathgar Township Electric Lighting Order, 1896. The undertakers are the Rathmines and Rathgar Improvement Commissioners, and the area of supply is the Township of Rathmines and Rathgar.

Sale Electric Lighting Order, 1896.—The undertakers are the Urban District Council of Sale, and the area of supply is the Urban District of Sale. The provisions in these orders are similar to those in the case of Bray.

Great Berkhamsted and Northchurch Electric Lighting Order, 1896.—The undertakers are the Bedford Electric Light Company, Limited, and the area of supply is a portion of the Parishes of Great Berkhamsted and Northchurch.

Great Crosby and Waterloo Electric Lighting Order, 1896.—The undertakers are the Liverpool District Lighting Company, Limited, and the area of supply is the Urban District of Great Crosby and the Urban District of Waterloo-with-Seaforth.

Margate Corporation Electric Lighting Order, 1896.—The undertakers are the Corporation of Margate, and the area of supply is the Borough of Margate.

Pembroke Township Electric Lighting Order, 1896.—The undertakers are the Pembroke Township Commissioners, and the area of supply is the Pembroke Township. The provisions of all these orders are on the same lines as above.

St. Saviour's District Electric Lighting Order, 1896.—The undertakers are the County of London and Brush Provincial Electric Lighting Company, Limited, and the area of supply is a portion of the District of the St. Saviour's District Board of Works. The provisions are similar to Camberwell.

Battersea Electric Lighting Order, 1896.—The undertakers are the Vestry of the Parish of St. Mary, Battersea, and the area of supply is the Parish of St. Mary, Battersea. This order contains provisions for prohibiting the supply of energy by the undertakers beyond the area of supply, otherwise than under the authority of Parliament, or under a license granted by the Board of Trade; for prohibiting the use of overhead wires without the consent of the Board of Trade and the London County Council; and for enabling the County Council to require the undertakers to place their mains, etc., in subways, where such subways exist.

Camberwell Electric Lighting Order, 1896.—The undertakers are the County of London and Brush Provincial Electric Lighting Company, Limited. The area of supply is a portion of the Parish of St Giles, Camberwell, and besides similar provisions to the Battersea order the order contains provisions for securing that the undertakers shall not purchase or acquire the undertaking of, or associate themselves with, any other company or person supplying energy under any license, provisional order, or special Act within the Administrative County of London, unless the undertakers are authorised by Parliament to do so, and for authorising the local authority to purchase the undertaking at any time after the commencement of the order, on certain terms specified in the order.

The following are the applications for provisional orders received by the Board of Trade since the date of the last report, together with the names of the promoters and how dealt with by the Board of Trade:

Allerton, Woolton, Childwall and Garston Electric Lighting Order.—The Urban Districts of Allerton, Little Woolton Much Woolton, Childwall, and Garston.—Liverpool District Lighting Company, Limited.—The promoters failed originally to produce the consents of certain of the local authorities, and the Board of Trade directed that a local enquiry should be held. The consents of the local authorities were subsequently produced, and the Board of Trade granted the order.

Ambleside Electric Lighting Order.—The Urban District of Ambleside.—Windermere and District Electricity Supply Company, Limited.—The promoters failed to produce the consent of the local authority, or to satisfy the Board of Trade that it should be dispensed with, and the Board of Trade refused to grant the order.

Ashton-on-Mersey Electric Lighting Order.—The Urban District of Ashton-on-Mersey and a portion of the District of the Bucklow Rural District Council.—Altrincham Electric Supply, Limited.—Order granted.

Bath Electric Lighting Order.—The City of Bath.—The Corporation.—Order granted.

Bath Electric Lighting Order.—The City of Bath.—City of Bath Electric Lighting and Engineering Company, Limited.—An application was also received from the local authority, to which preference was given by the Board of Trade in accordance with their usual practice, and this application was not therefore proceeded with.

Bray Township Electric Lighting Order.—The Township of Bray.—The Township Commissioners.—Order granted.

Bristol Suburban Electric Lighting Order.—The Urban Districts of St. George and Kingswood and a portion of the Urban District of Stapleton and of the Rural District of Warmley.—Great Western Electric Light and Power Company, Limited.—The promoters decided not to proceed with the application

Colwyn Bay and Colwyn Electric Lighting Order.—The Urban District of Colwyn Bay and Colwyn.—The Urban District Council.—Order granted.

Cork Electric Lighting Order.—The City or Borough of Cork.—The Corporation.—Order granted.

Cowes Electric Lighting Order.—The Urban District of Cowes.—The Urban District Council.—Order granted.

Devonport Corporation Electric Lighting Order.—The County Borough of Devonport.—The Corporation.—Order granted.

Folkestone Electric Lighting Order.—The Urban District Folkestone.—The Corporation.—Order granted.

Gloucester Corporation Electric Supply Order.—The City o Gloucester.—The Corporation.—Order granted.

Godalming Electric Lighting Order.—The Municipal Borough of Godalming.—The Corporation.—Order granted.

Great Berkhamsted and Northchurch Electric Lighting Order.—Portions of the Parishes of Great Berkhamsted and Northchurch.—Bedford Electric Lighting Company, Limited.—Order granted.

Great Crosby and Waterloo Electric Lighting Order.—The Urban Districts of Great Crosby and Waterloo-with-Seaforth.—Liverpool District Lighting Company, Limited.—Order granted.

Huddersfield Electric Lighting Order.—The County and Municipal Borough of Huddersfield.—The Corporation.—Order granted.

Ipswich Electric Lighting Order.—The Borough of Ipswich.—County of London and Brush Provincial Electric Lighting Company, Limited.—The promoters failed to produce the consent of the local authority, or to satisfy the Board of Trade that it should be dispensed with, and the Board of Trade refused to grant the order.

Keswick Electric Lighting Order.—The Township of Keswick and portions of the Townships of St. John's, Castlerigg, and Wythburn, Underskiddaw, and Above Derwent.—Keswick Electric Light Company, Limited.—An application was also received from the local authority, to which preference was given by the Board of Trade, in accordance with their usual practice, and this application was not therefore proceeded with.

Digitized by Google

Keswick Electric Lighting Order.—The Urban District of Keswick. The Urban District Council.—Order granted.
Kettering Electric Lighting Order.—The Urban District of Kettering.—The Urban District Council.—Order granted.
King's Lynn Electric Lighting Order.—The Borough of King's Lynn.—The Corporation.—Order granted.
Kingstown Township Electric Lighting Order.—The Township of Kingstown.—The Township Commissioners.—Order granted.
Liverpool Electric Lighting Order.—The City of Liverpool.—The Corporation.—Order granted.
Manchester Electric Lighting Order.—A portion of the City of Manchester.—The Corporation.—Order granted.
Margate Corporation Electric Lighting Order.—The Borough of Margate.—The Corporation.—Order granted.
Merthyr Tydfil Electric Lighting Order.—A portion of the Urban District of Merthyr Tydfil.—J. C. Howell, Limited.—Order granted.
Middleton Electric Lighting Order.—The Borough of Middleton. The Corporation.—Order granted.
Newmarket Electric Lighting Order.—The Urban District of Newmarket and a portion of the Rural District of Newmarket.—Newmarket Electric Light Company, Limited.—The promoters failed to produce the consent of the Urban District Council or to satisfy the Board of Trade that it should be dispensed with, and the Board of Trade refused to grant the order.
Pembroke Township Electric Lighting Order.—The Township of Pembroke.—The Township Commissioners.—Order granted.
Prescot District Electric Lighting Order.—The Urban District of Huyton-with-Roby, and the Parishes of Rainhill, Whiston, and Eccleston.—British Insulated Wire Company, Limited.—The promoters failed to produce the consents of the local authorities, and the Board of Trade directed that a local enquiry should be held. After consideration of the report made by the inspector appointed to hold the enquiry, the Board of Trade were of opinion that no reasons had been advanced sufficient to justify them in dispensing with the consents of the local authorities, and they refused to grant the order.
Queenstown Township Electric Lighting Order.—The Township of Queenstown.—The Town Commissioners.—Order granted.
Rathmines and Rathgar Township Electric Lighting Order.—The Township of Rathmines and Rathgar.—The Improvement Commissioners.—Order granted.
Sale Urban District Council Electric Lighting Order.—The Urban District of Sale.—The Urban District Council.—Order granted.
Wells (City of) Corporation Electric Lighting Order.—The City of Wells.—The Corporation.—Order granted.

THE COUNTY OF LONDON.

Battersea Electric Lighting Order.—The Parish of St. Mary, Battersea.—The Vestry.—Order granted.
County of London (South) Electric Lighting Order.—The District of the St. Saviour's District Board of Works, and the Parishes of St. Mary, Newington; St. Mary, Lambeth; St. Giles, Camberwell; and St. Mary, Battersea.—County of London and Brush Provincial Electric Lighting Company, Limited.—Two orders granted: one in respect of a portion of the Parish of Camberwell; the other in respect of a portion of the District of St. Saviour's District Board of Works.
Newington Electric Lighting Order.—The Parish of St. Mary, Newington.—The Vestry.—Representations were received from ratepayers objecting to the application, and the Board of Trade directed that a local enquiry should be held. After consideration of the report made by the inspector appointed to hold the enquiry, the Board of Trade refused to proceed with the application.

LICENSES.

The following applications for licenses have been received since the date of the last report, and have been dealt with in the manner shown below:

The Corporation of Bangor.—The Municipal Borough of Bangor and portions of the Parishes of Pentir and Llandegai.—Representations were received from ratepayers objecting to the application and the Board of Trade directed that a local enquiry should be held. After consideration of the report made by the inspector appointed to hold the enquiry, the Board of Trade refused to proceed with the application.
Earl de la Warr and Robert Kersey.—A portion of the Parish of Bexhill.—Still under consideration.
The Corporation of Morley.—The Borough of Morley.—Still under consideration.
The Wallasey Urban District Council.—The Urban District of Wallasey.—Still under consideration.

Since the date of the last report the Board of Trade have approved a deed transferring to the Harrow Electric Light and Power Company, Limited, the powers, duties, and liabilities (with certain modifications and exceptions) under a provisional order granted to the Harrow Local Board in 1894; and the undertaking authorised by the Fareham Electric Lighting Order, 1892, has with the consent of the Board of Trade, been transferred by the Fareham Electric Light Company, Limited, to the Fareham Urban District Council.

New model regulations for securing the safety of the public and for ensuring a proper and sufficient supply of electrical energy have been made by the Board of Trade, and have been imposed upon all undertakers supplying energy.

Revised regulations for the purposes of Section 4 of the Electric Lighting Act, 1888, are now under consideration by the Board of Trade, and will shortly be issued.

OLDHAM ELECTRIC LIGHTING ACCOUNTS.

The following is the statement of accounts for the year ended March 25 last:

Expenditure on Capital Account.

	£	s.	d.
Supply station:			
Engines and dynamos	2,060	18	7
Batteries	329	17	7
Switchboard	346	13	9
Steam-pipes	155	16	11
Sundries	37	19	10
	2,931	6	8
Street mains	3,358	2	4
	£	s.	d.
Gross revenue for the year	3,847	14	3
Gross expenditure	1,577	17	9
Balance carried to net revenue account	2,269	15	7
Interest on loans, £813. 8s. 4d.: sinking fund, £608. 12s. 7d.	£1,422	0	11

The receipts for the present year and the balance brought forward from the previous year make the amount to be carried forward to the credit of the next year £1,749. 18s. 3d. The price of energy supplied to all consumers has been 6d. per unit. The minimum quarterly charge for energy was reduced from 10s. to 5s. from June last, and the charge for meter rent also reduced from that date. The greatest quantity supplied in 24 hours was on January 6, and was 1,242 units, against 651 last year. Applications for additional borrowing powers to meet the growing demand for the light have been acceded to by the Local Government Board to the extent of £15,000. The total length of the mains laid on March 25 was 5,763 yards.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Prestwich.—Tenders for putting into thorough repair the existing telephone system and electric bells at the county asylum, Prestwich, are invited. Full particulars on application at the asylum.

Bucharest.—Tenders will be received up to August 8 by the Roumanian Government (Department of Posts and Telegraphs) for the electric lighting of the new Posts and Telegraph building at Bucharest.

Spandau.—Tenders are wanted at the Royal Small-Arms Factory for 900 incandescent electric lamps by July 17. Particulars are obtainable for 75pfg. (9d.) from Die Königl. Direktion der Gewehrfabrik (Geschäftszimmer No. 21), Spandau.

Simla (India).—The Municipality is inviting tenders for lighting by electric light for a term of years the principal thoroughfares and buildings belonging to the Municipality. Tenders must be submitted by September 1 next. Should any proposal be accepted, the Municipality will afford the successful tenderer all facilities to extend the system of lighting to private houses.

Cologne.—Tenders are required by the Municipal Authorities for the construction and working of electric tramways in the city of Cologne to an aggregate length of 20·3 kilometres (12½ miles). Specifications, plans, and particulars are obtainable for 10 marks (10s.) from der Registrateur B, des Oberbürgermeisteramt, Köln, Germany, and tenders must be in by November 6.

Madras.—Tenders are invited for the lighting by electricity of Government House, Madras, including the banqueting-hall and aide-de-camps' bungalow, and also for the lighting of Government House, Guindy, including the military secretary's bungalow. For particulars application must be made to the consulting architect to the Government, Chepank, Madras. Tenders will be opened on November 11, 1896.

London, W.—Tenders are required for the supply of (1) coal to the electric lighting station, South Ealing; and (2) coal and coke to the other depôt of the Urban District Council. Printed forms of tender, conditions of contract, etc,, and any further particulars can be obtained on application to Mr. C. Jones, C.E., surveyor to the Council, between 10 and 4. Tenders, in envelopes provided, to be delivered by 4 p.m. on 16th inst.

Lisbon.—The Royal Portuguese Railway Company want tenders by July 22 for the supply of 10,000 porcelain insulators with galvanised iron supports, 200 sheets of asbestos (1 metre square by 2 millimetres thick), and about 2½ tons of galvanised iron wire. The tenders are to be addressed to the Chief of the Stores Department at Santa Apolonia Station, Lisbon and particulars can also be obtained at Paris, Rue de Châteaudun 28.

Voghera (Italy).—In view of the expiration of their contract with the local gas company in 1898, the municipal authorities of Voghera are desirous of receiving during the present year propositions for the lighting of the town either by the electric light or a mixed system of gas and electricity. The population is 16,000. Application should be made to L'Administrazione Comunale, Voghera, who will give all particulars necessary.

Battersea (London).—The St. Mary's Vestry will receive tenders up to July 14 for a complete installation of the electric light for the town hall and municipal buildings. Specifications and con-

Digitized by Google

ditions can be obtained from Mr. R. Hammond, Ormond House, Great Trinity-lane, E.C., after a deposit of two guineas has been made with the Vestry Clerk, at the Vestry Offices, Lavender-hill, S.W. Clauses for the payment of trades union wages will be embodied in the contract.

Huddersfield.—Messrs. Learoyd Bros. and Co invite tenders for the wiring of the Trafalgar Mills. Copies of the specifications and general conditions can be obtained from Messrs. Shepherd and Watney, 71, Albion-street, Leeds, on payment of a cheque for £1. 1s, which will be returned on receipt of a bona fide tender. Tenders, endorsed "Electric Lighting," must be addressed and delivered to Messrs. Learoyd Bros and Co., Milnsbridge, Huddersfield, by 12 noon on July 7.

Mexico.—The municipal authorities of the city of Mexico are prepared to receive proposals for the street lighting by incandescent lamps for a period of eight years Tenders should be sent in by August 31. The Secretary of State for Foreign Affairs has received from the British Consul at Mexico a pamphlet issued by the Municipal Council of the city containing particulars as to the tenders, and this may be seen on application to the Commercial Department of the Foreign Office between the hours of 11 and 6.

San Juan (Puerto Rico).—H.M. Secretary of State for Foreign Affairs has received from H.M. ambassador at Madrid a copy of a Spanish Royal Order which has appeared in the *Gazette* inviting tenders for the construction and working of a telephone system in San Juan de Puerto Rico. A deposit of 800dol. must accompany each tender which will be considered on August 10. The copy of the Royal Order may be seen on application to the Commercial Department of the Foreign Office between the hours of 11 and 6.

Bedford.—Tenders are invited by the Urban Sanitary Authority for supply of steam coal to the electricity works, for one year ending July 23, 1897. The coal to be one of the following kinds: Annesley hard coal, Pilsley ditto, Linby ditto, or from some other approved colliery. Sealed tenders, endorsed "Tenders for Coal," to be sent to Mr. T. S. Porter, clerk, Town Hall, Bedford, by 14th inst, with samples of the coal proposed to be supplied. Every tender must be in a printed form, a copy of which may be obtained at the clerk's office. The person whose tender is accepted will be required to furnish the colliery certificate.

Ayr.—The Corporation invite tenders for the following stores for 12 months ending May 31, 1897, to be delivered at the Ayr burgh electricity works free of all charges: (1) best washed dross, 15 to 25 tons per week; (2) best long thread cotton waste per cwt.; (3) sponge cloths per gross; (4) engine-room stores; (5) picks, shovels, rammers, etc., for street work; (6) stationery; (7) general ironmongery; (8) plain smith's forgings, per lb.; (9) cleaning, painting vermilion and numbering in gilt the electric lamp-posts. All necessary information may be obtained from the burgh electrical engineer, Mill-street, Ayr, where patterns may be seen. Tenders, sealed and endorsed, to be lodged with Mr. A. G. Young, town clerk, Ayr, by 6th inst.

Wallasey.—For condensing apparatus and steam and exhaust pipes in connection with their electric light installation, tenders are invited by the Wallasey Urban District Council. Drawings may be seen, and copy of the specification obtained, on application to the engineer, Mr. J. H. Crowther, at the Gas and Water-works, Great Float, near Birkenhead, on payment of £2. 2s., to be returned on receipt of a bona fide tender. Sealed tenders, on the form provided, addressed to the chairman of the Gas and Water Committee, and endorsed "Tender for Condensing Apparatus, etc," to be delivered at the office of Mr. W. Danger, clerk to the Council, Public Offices, Egremont, Cheshire, by 4 p.m. on July 16 The contractor will be required to enter into a bond, with approved sureties, for the due performance of the contract.

Army Contracts.—The Secretary of State for War gives notice that tenders for specific quantities of the following articles will probably be invited from time to time during the next twelve months — namely: submarine mining electrical instruments, telegraph cable and wire, etc. Manufacturers who may wish to be applied to when tenders are required should address the Director of Army Contracts, War Office, Pall-mall, S.W., by letter, stating the particular articles which they manufacture, and the names of at least two well-known firms or public bodies who have purchased from them, and are in a position to certify as to the quality of their productions. Applications unaccompanied by references will not be noticed. Firms whose names are already on the War Office list need not apply, as forms for tendering will be sent to them in due course.

Kingston (Jamaica).—The Colonial Government invite electric tramway contractors willing to undertake the establishment and working of a system of rapid transit to send in applications for the grant of a license by the Governor in Privy Council under the Tramways Law, 1895. In all applications the principal questions to which attention should be directed are the following: (*a*) the amount of capital which the applicants are prepared to subscribe; (*b*) the system which it is proposed to establish; (*c*) the mileage of lines to be laid; (*d*) the fares to be charged; (*e*) the frequency of the service; (*f*) the length of the license required by applicants; (*g*) the guarantee which the applicants offer for the satisfactory performance on their part of any obligations devolving on them. Plans of the city of Kingston and part of the parish of St. Andrew, showing the routes on which the present tramway lines are laid, and copies of the law under which licenses are granted and of the rules made thereunder by the Governor in Privy Council, may be seen at the office of the Crown Agents for the Colonies, Downing-street, London, S.W. All applications must be delivered not later than July 31, 1896, in a sealed packet, marked on the outside "Application for Tramway License," to the clerk of the Privy Council, Kingston, Jamaica. Kingston has its principal means of transit at present supplied by the Jamaica Street Car Company by horse tramcars, the entire length of lines laid being about 12 miles. The concession granted by the Legislature of the island to the Jamaica Street Car Company will shortly expire.

RESULTS OF TENDERS.

Burnley.—The Gas and Electric Lighting Committee have accepted the tender of Messrs. Callender's Bitumen Telegraph and Waterproof Company, Limited, London, for the supply of electric cables for the Church-street extension at £600. 4s.

Brussels.—For converting local tramways for electric traction on June 17 the lowest of six tenders were those of the Compagnie générale de traction et d'électricité, of Paris, at 933,056fr. for lattice poles and 980 331fr. for tubular poles. The tenders of the Union Elektricitäts-Gesellschaft, Berlin, were 1,075,000fr. and 1,175,000fr. On a basis of so much per car mile the tenders of the Union were slightly the lower. No English firms tendered.

BUSINESS NOTES.

Jandus Arc Lamp.—We hear that, although the works have only been at full work for a few months, 700 of these lamps are in daily work.

Folkestone.—The Town Council have appointed Dr. Hopkinson, F.R.S., to investigate the agreement to be made with Mr. Hopkins for the sale of the order.

Devizes.—A firm has applied to the Corporation for a license to enable them to supply the electric light to business places in the immediate vicinity of their works.

City of London Electric Lighting Company, Limited.—The warrants for interest due on the 30th ult. on this Company's debenture stock have been posted.

Telegraph Messengers.—Lord Wolesley has held an inspection of telegraph messengers in Hyde Park. He expressed satisfaction at the way the drill, etc., was performed.

Newcastle.—An installation of electric light has been fitted in the new Presbyterian church at Heaton, the work being carried out by Messrs. Lummis, Paterson, and Co., of Heaton.

Auto-Electro Feed-Water Purifier Company, Limited.—This Company has been formed to acquire and turn to account a patent for the purification of the feed water of steam-boilers.

Address.—Mr. F. C. Allsop, manufacturing electrician, has dissolved partnership, and is now carrying on business entirely by himself, as in former times, at 97, Queen Victoria-street, E.C.

Dover.—The Corporation have resolved to support a petition to the borough member for the increase of the weight of motor vehicles in the Act now before Parliament of two to four tons.

The Telephone Trunk Line.—All the principal towns in the Midland and Eastern Counties are now in intercommunication, and the connections to the Northern Counties will follow shortly.

Western and Brazilian Telegraph Company.—For the week ending June 26 the receipts, after deducting 17 per cent. payable to the London Platino-Brazilian Telegraph Company, were £2,856.

Eltham (Kent).—The Guardians propose to connect the workhouse and the doctor's house by telephone The distance is 3½ miles, and the question will be settled at the meeting next week.

Whitehaven.—The Guardians wanted the road leading to the workhouse lighted by electricity, but it has since been ascertained that the road is not included in the limits of the borough under the electric lighting order.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending June 28 amounted to £1,219, as compared with £1,193 in the corresponding week of the previous year, being an increase of £26.

Bristol Tramways and Carriage Company, Limited.—The traffic returns for the week ending June 26 were £2,333. 19s. 4d., compared with £2,110. 13s. 3d for the corresponding period of last year, being an increase of £223. 6s. 1d.

British Electrical and Industries Company, Limited.—This Company has been started to acquire and carry on any businesses connected with the working of electricity in all its branches, and also to carry on the business of a supply stores.

Merthyr.—Messrs. J. C. Howell, Limited, have given notice to the Urban District Council of their intention to apply in the next session for a provisional order for lighting with electricity the whole of the area under the Council's jurisdiction.

Brighton.—At a meeting of the Recreation Grounds Committee of the Town Council an application was read from Mr. T. Duff Barnett, B.A., for permission to run two electric carriages in Preston Park for hire. The application was refused.

Electrical Manufacturers, Limited.—This Company has been formed to carry on the business of a dealer in electrical apparatus, electrician, and electrical engineer, carried on by H. E. Childs at 223, Upper Thames-street, E.C., and to adopt an agreement with the said vendor.

Cork.—A special assembly of the Council of the city will be held to-day to consider the application of the Cork Electric Tramway Company, and the amendments made on the draft Order in Council for construction of same, as recommended by the Public Works Committee of June 24.

Bath.—A Select Committee of the House of Commons, presided over by Colonel Gaunter, has passed a Bill confirming a pro-

Digitized by Google

visional order of the Board of Trade authorising the Corporation to undertake the electric lighting of the city. There was no opposition to the confirmation of the order.

Consolidated Telephone Company, Limited.—The directors of this Company have resolved to recommend to the shareholders at the approaching annual general meeting that, subject to audit, a dividend at the rate of £1. 10s. per cent. per annum, less income tax, to be paid for the year ending March 31, 1896.

Fermoy.—A public meeting has been held to consider an offer made by Mr. F. J. Warden-Stevens, A.M.I.E.E., with regard to electric lighting. He stated that if a sufficient number of lights were guaranteed a private company would be formed for the purpose, the consent of the Commissioners having been obtained.

Southall-Norwood.—The postal authorities having applied for permission to erect posts and wires along the Church-path to Norwood Green Post Office, the Urban District Council decided that this permission be not given, but that permission be given to the wires being carried underground along the Church-path and Norwood-road.

City and South London Railway.—The returns for the week ended June 28 were £891, compared with £780 for the corresponding period of last year, being an increase of £111. The total receipts for the half-year terminating as above were £24,069, compared with £23 873 in the same period of the preceding year, being an increase of £196.

Portsmouth.—The Electric Light Committee of the Town Council have decided to send a deputation to towns in the Midlands to consult the engineers of electric light works where the types of engines which the committee contemplate purchasing are at work. This has been done in order to obtain the information for the guidance of the committee.

Aberdeen.—The interior of the Advocates' Hall Buildings is being fitted up with the electric light. The contract is in the hands of Messrs. Shirras, Laing, and Co., and is being carried out under the superintendence of their engineer, Mr. Botting. The other apartments of the suite and the spacious passages are also to be lighted by electricity. The current will be supplied from the Corporation mains.

Greenwich.—At the District Board meeting a letter was read from the secretary of the Blackheath and Greenwich District Electric Light Company, Limited, forwarding formal notice of application by that company for a provisional order under the Electric Lighting Acts, 1882-1888, authorising that company to supply electricity for public or private purposes within the area of this Board. It was referred to the Greenwich Committee.

East Grinstead (Sussex).—A notice was received at the Urban District Council meeting from the electric lighting company stating that they intended to apply forthwith, under the Electric Lighting Acts, to the Board of Trade for a provisional order authorising them to supply electricity for public and private purposes within the urban district of East Grinstead. The letter was referred to the General Purposes Committee in order to ascertain what rights the Council had to protect.

Rontgen Rays.—The natural research department of the Animals Institute, under the auspices of Sir Henry Hawkins, president, and Prince Edward of Saxe-Weimar, are offering gold medals and other prizes for improvements in the X rays to aid the diagnosis of disease and lameness, and for the best developed photographs of the limbs and internal organs of the human being and the lower animals. Applications should be made to Prof. Matthews, 75, Kinnerton-street, Wilton-place, S.W.

Newport.—A Local Government Board enquiry was held at the Town Hall Newport, on Tuesday, by Mr. F. H. Tulloch, M.I C.E., one of the Government inspectors, with reference to an application by the Newport Corporation to borrow £12,000 additional for the town's electric light installation, making, with the £28 000 already sanctioned, £40,000. The Board of Trade have appointed Mr. Hugh Erat Harrison, principal of the Electrical Standardising Institution, Charing Cross-road, E.C., electric inspector to the Corporation.

Keswick.—An adjourned meeting of the Urban District Council has been held to discuss the electric lighting question. Memorials, signed by about 180 ratepayers, were read requesting the Council not to take any further steps with regard to purchasing the electric lighting company's works until the ratepayers had been consulted. After a somewhat stormy discussion it was ultimately decided that a committee of five be appointed to consider the report and the company's proposal, and to report to the next monthly meeting of the Council.

Kingswood (Bristol).—At a meeting of the Urban District Council a letter was read from the Western Counties Electric Lighting Company, stating that if the Council were going to do anything in the matter of purchasing the electric plant they should do so at once, and the matter must be brought to a speedy and definite decision. The letter was signed by the chairman of the company (Mr. H. Daniell). Following the advice of their solicitor (Mr. Seymour Williams), the Council decided to leave the matter in abeyance.

Windermere.—The Urban District Council have decided to erect eight new electric lamps in Cooks House-road and at Troutbeck Bridge. The Telephone Company having failed to get permission from the owner of Calgarth to put their line of wires over the estate, and being unable to follow the main road from Cooks House to Troutbeck Bridge without contact with the telegraphic communication, applied for leave to carry the wire from Millerground across by Cooks House to Brow Head and thence down by the Sun Hotel to the main road again. The Council have granted leave on payment of a rental of 2s. 6d. per pole.

Harrow.—At the meeting of the Urban District Council a letter was read from the Board of Trade enclosing a copy of a letter they had addressed to the Harrow Electric Light Company, who had applied for an extension of time so that the compulsory works could be completed. In their letter the Board of Trade said they had no power to extend the time, but under the circumstances they would allow six months to pass from the 3rd prox. for the consideration of the question of revoking the order. The Clerk said that was apparently their way of granting extensions.

Appointment Vacant.—The School Board for London are about to appoint an assistant science demonstrator, who will be required to visit schools under the direction of the Board for the purpose of giving instruction in mechanics. Salary £130, rising by £5 per annum to a maximum salary of £175 per annum, together with expenses not to exceed £75 per annum. Applications, which must be made on forms to be obtained from the clerk of the Board, must reach the clerk of the Board, School Board for London, Victoria-embankment, W.C., not later than Saturday, July 4, 1896, marked outside "Assistant Science Demonstrator."

Edinburgh.—Sheriff Rutherford has issued an interlocutor in an action for damages for breach of contract raised in the Edinburgh Sheriff Court by Mr. A. A Rose, 26, Regent-terrace, Edinburgh, against Smiths and Co., Limited, electrical engineers, 89, George-street, Edinburgh. The plaintiff claimed the sum of £29. 6s. as loss sustained by him through the defendants' failure to execute their contract with expedition. The sheriff, *inter alia*, found that the plaintiff's house should have been ready for occupation at least a fortnight sooner than it was, and therefore found the defendants liable in damages, which he assessed at £21. 6s and expenses.

Electric Lighting Machinery.—We have received from Messrs. G. E. Belliss and Co., of Birmingham, an illustrated catalogue of the high-speed electric light engines for which they are so well known. The catalogue chiefly refers to the self-lubricating type. which has proved itself so efficient for lighting and power work generally that Messrs. Belliss have been obliged to greatly extend this department of their works and to add a very complete new testing-house to enable dynamo machinery of all sizes to be thoroughly tried under working conditions before being despatched. They have already built or have under construction engines of this type developing nearly 30,000 h.p.

Hull.—At a meeting of the Finance Committee of the Corporation, the question of the proposed extension of the electric light in the borough, and the suggested borrowing of £42,000, came up for consideration. The borough treasurer (Mr. Milner) presented a report, and the Chairman explained that the borrowing of £42,000 would not incur any additional charge upon the rates of the borough. He moved that the report be adopted, and that the sanction of the Local Government Board be asked for borrowing the £42 000. The Chairman of the Electric Lighting Committee said that the extension was an absolute necessity, and he deprecated that time should be lost. The report was adopted.

London, E.—After investigations extending over a year, the Special Electric Lighting Committee appointed by the Mile End Vestry presented their report last week The committee find that the proposal to utilise the waste heat of the dust destructors for the purpose of generating electricity has not been successful. At Brighton it was found that the charge for electricity was only equal to 2s. 3d. per 1,000ft of gas, and that it was hoped soon to supply electricity cheaper than oil, and that last year a net profit of not less than £6,000 had been made. After having fully considered the information obtained, the committee are of opinion that it is advisable to light the hamlet by electricity, and recommend that application be made to the Board of Trade for a provisional order to enable the Vestry to do so.

Dublin.—As we announced last week, the Dalkey Electric Tramway has been purchased by the Dublin United Tramway Company for £273,000. The line will be worked by a Board consisting of members of the Thomson-Houston Company and of the Dublin United Company, Mr. William Anderson acting as secretary and manager, and this arrangement will be continued till the amalgamation of the undertaking is finally completed. We understand that as soon as the Dublin United Company obtain their Bill now before Parliament for leave to lay down lines in the Clontarf township, the works will be promptly carried out under the three-phase system now in operation for the Dalkey service. A new power station will, however, have to be built at Clontarf if no authority can be got to lay the cable from Ballsbridge.

Walsall.—A special meeting of the Town Council has been held to pass a formal resolution—pursuant to the powers conferred on the Council in that behalf by the Walsall and District Tramways Orders 1880 to 1884, the Staffordshire Tramways (Extension) Order of 1882, and the South Staffordshire Tramways Act of 1889, or some or one of them—in favour of the Council, with the approval of the Board of Trade, requiring the South Staffordshire Tramways Company to sell to the Council so much of the undertaking of the company as is within the borough of Walsall. The town clerk, in the name and on behalf of the Council, was authorised to give notice, under the common seal of the borough, to the South Staffordshire Tramway Company, requiring them to sell, and to take all other necessary proceedings for enabling the Council to put in force the compulsory powers of purchase now vested in them.

Manchester. — At the meeting of the City Council, Mr. Alderman Higginbottom moved the adoption of the annual report on the electric light, which showed, he said, in spite of the reduction in price from 8d. to 6d. per unit, a profit for the year of £11,138. The actual profit was £14,629, but it had been thought advisable to place the sum of £3,900 to what was called renewals

Digitized by Google

account for replacement of plant. One gratifying feature of the year's work was the increased use of electricity for motor purposes. The extensions of the plant and mains at present in progress would soon be completed, but if the demand continued to increase as at present, still further extensions would be needed next year. For the purpose of a getting a day load, the current was sold for motive purposes at from 1½d. to 2d. per unit, according to the quantity used. Several large establishments took the current on such terms. The report was adopted.

Glasgow.—The past year, which is the first full year the tramway have been worked by the Corporation, has been one of steady progress. The traffic receipts have amounted to £328,827, and other receipts to £5,550, making a total of £334,377. The working expenses amounted to £251,110, leaving a balance of £33,267, which has been disposed of as follows: interest on capital, £12,657; sinking fund, £10,542; payment to common good in lieu of mileage rate, etc., £9,000; depreciation written off capital, £17,809; permanent-way renewal fund, £17,000; and general reserve fund, £16,259. The Sub Tramway Committee on traction have agreed to recommend the Tramway Committee as an experiment, to immediately construct an installation on the overhead electric system on the Kelvinside-Dennistoun route. It is understood that the chief objection to the underground conduit system, which was also considered, was the extra initial outlay that its construction would involve, and also the fact that so far it was only in its experimental stage.

Westminster.—At a Vestry meeting the Libraries and Baths Committee reported that they had caused a specification to be prepared by the surveyor for improving the electric lighting installation, which had proved to be insufficient when fully in operation in the libraries and the baths at the same time. They had caused tenders for the proposed work to be obtained from six firms, the lowest of which amounted to £358. As this amount exceeded their expectations, they had ordered that enquiries be made as to the possibility of detaching that part of the installation which lighted the library, and obtaining current from the company supplying the district. The committee hoped to find that course more economical, as preventing the large outlay required for increasing the accumulators and for running the dynamo when, as is frequently the case, the light has to be generated exclusively for the library. As the matter had become urgent, the committee recommended the detachment and the supply of the library by a public company. After some discussion the report was adopted.

London Lighting Extensions.—The London County Council have given their sanction to the following notices: The Charing Cross and Strand Electricity Supply Corporation to lay mains in Leicester-square (one side) Spur-street, New Coventry-street, and in Whitcomb-street and across it in two places; the Vestry of St. Pancras to lay mains in Gray's-inn-road, Chalk Farm-road, Judd-street, and Cromer street; the House-to-House Electric Light Supply Company to lay high and low tension mains in Cromwell-road, and a low-tension main in Cromwell-road West; the London Electric Supply Corporation to lay distributing mains, consisting of lead-covered cables drawn into cast-iron pipes, in Blackfriars-road and Upper Ground-street, and in King's road and Flood-street, Chelsea; the St. James and Pall Mall Electric Light Company to lay mains in Pall-mall-place and across Pall-mall; the County of London and Brush Provincial Electric Lighting Company to lay low-tension mains on the west side of Goswell-road. The Vestry of Islington, under the provisions of the Islington Electric Lighting Order, 1893, gave notice of intention to lay mains in Holloway-road, Caledonian-road, North-street, Wharfdale-road, and Wellington-road; but the Vestry is the undertaker under the order, and the Council has no power of approval or disapproval of these works.

Exeter.—The Special Committee on Electric Lighting reported to the City Council at the last meeting on the arrangements to be made for the future working of the undertaking. The committee were of opinion that it was desirable that, in addition to supplying the light, the Council should be in a position to supply and repair electrical fittings in the houses of their customers. The committee recommended that the electrical lighting works department be considered one of the departments of the work of the Council, under the control of the surveyor; that an electrical engineer be appointed in charge of the works who should be responsible to the city surveyor for the conduct and work of his subordinates; that Mr. Munro, the present electrical engineer to the company, be appointed electrical engineer at a salary of £200 per annum; and that the following staff be also appointed: leading engine-man, £2 per week; second engine-man, £1. 10s. per week; three stokers, at an aggregate of £3. 12s. per week; one foreman jointer, £2 2s. per week; four electricians, £70, £60, £52, and £52 respectively. It was decided that the staff should not exceed the number mentioned in the report, and it was also decided to advertise for an electrical engineer at a salary of £200 per annum, rising £10 annually to a maximum of £250. With these alterations the report was adopted.

Hampstead.—At the meeting of the Vestry, Mr. Reed said that the liberal laying of electric lighting mains—the Vestry had laid mains in nearly every road they had been asked to—was producing a good result. At the present time about 25 miles of distributing mains were laid. The number of customers taking the light had been increased by about a hundred since Christmas. At that time 261 applications for the light had been received, and of that number 255 were then connected. Now the total number of applications amounted to 385, and 355 connections had been made. There was now an equivalent of 25,292 8-c.p. lamps being supplied as compared with 19,407 at Christmas. Upon the recommendation of the Lighting Committee mains for the supply of electric current to private consumers were ordered to be laid in Shoot-up-hill, St. John's Wood-park, and a small portion of Belgrave-road. It was also decided that, during the pleasure of the Vestry, the high and low tension cables required for future extensions of the electric supply be ordered from the British Insulated Wire Company at the schedule of prices quoted by them, subject to their entering into a proper contract to supply the same. The Lighting Committee recommended that the Willesden District Council be informed that the Vestry are not prepared to entertain the suggestion of the Council that the lighting of the High-road, Kilburn, might be carried out by each authority, in the sections now repaired by them, by electric lighting or such other method as each might deem desirable. This was adopted. It was also decided with reference to the letters from the Westinghouse Electric Company, Limited, as to the system of supply used by the Vestry coming within the claims of the Hopkinson patent, and as to granting a license, that the Vestry should deny any liability in the matter of such patent. In reply to a question respecting the charge to the electric lighting account for repairs executed by the surveyor's department to the trenches in which the electric light cables are laid, Mr. Williams said that the charges were made in just the same manner as they would be to a public company under the same circumstances.

Hammersmith.—The Electric Lighting Committee having considered the tenders for electric lighting works brought up the following report at the meeting of the Vestry: "The work has reference to (*a*) supplying and laying high-pressure and low-pressure cables and pipes; (*b*) the supply and erection of arc lamps and lamp-posts; (*c*) the supply and erection of transformers and sub-station equipment; (*d*) the supply and erection of a five-ton overhead travelling crane. With regard to Schedule A, there are eight tenders, and the prices range from £9,526. 10s. to £16 096. 19s. The engineer has reported to us fully upon the tenders and we have also made the necessary enquiries; as the result, we recommend the Vestry to accept the tender of Callender's Bitumen Telegraph and Waterproof Company for Schedule A at the sum of £10,170. 2s. 11d. With regard to Schedules B and C, the tenders also vary; as to B, there are six tenders, the prices ranging from £2,672 5s. to £3,797, and as to C, there are seven tenders, varying from £857 to £1,155. We have also had a full report upon these from the engineer, and after very careful consideration we recommend the Vestry to accept the tender of Messrs. Siemens Bros., Limited, for Schedule B at £2,702 and Schedule C at £935. As to Schedule D the same remarks apply, and we recommend the Vestry to accept the tender of Messrs. Marshall, Fleming, and Jack, of Motherwell, Lanarkshire, for the supply and erection of the five-ton overhead travelling crane for the sum of £157, subject to the engineer receiving satisfactory replies to the enquiries he is making. According to the specification, firms tendering for Schedule A are required to give a guarantee through an approved guarantee society, at their own cost, to maintain certain insulation resistances for a period of five years from the date of completion of the works. Messrs. Callender write and inform us that they have applied to all the guarantee societies in London, and that they all decline to undertake this form of guarantee. Messrs. Callender offer to furnish the Vestry with two good and substantial sureties who will give the required guarantee, and under the circumstances we recommend that the Vestry accept the sureties, subject, of course, to our being satisfied after due enquiry." The tenders were accepted by the Vestry.

Nottingham.—Colonel A. G. Durnford, R E., an inspector under the Local Government Board, has held an enquiry with reference to the application of the Corporation for sanction to borrow £40,000 for purposes of electric lighting. Mr. H. Talbot, electrical engineer, stated that the works were started in 1892. He had designed the works and carried them out. The first sum of capital raised was £45,000. That sum of money was expended in the purchase of land, building, machinery, and mains. At the end of March, 1895, they had 8,267 8 c.p. lamps, and at the end of March, 1896, they had 15,466 lamps. On March 2, the date this application was made, they had 202 customers, the total number of lamps being 18,570. Applications were constantly coming in for extensions. In order to meet the requirements a large sum would have to be expended as capital. At the end of last winter the whole of the plant was utilised, and they got very near the limit. He had made an estimate of the cost of the extension, which would amount to £40,000. The demand was such that the Electric Lighting Committee had ordered him to go on with some portion of the works. There were several special applications which they must supply next winter. There were large buildings being erected, and no gas put in. There was also an application in connection with the new general post office, where about 1,000 lamps would be required. The Town Clerk added that the residents on the Nottingham Park Estate had informed the Corporation that unless they could supply the electric light within a reasonable time, the Duke of Newcastle would supply it himself. The following is the estimate of the amount of capital required to be borrowed for the extension of the undertaking: 162,900 cubic feet in buildings, consisting of engine-room, boiler-room, and coal-bunkers, and including foundations for engines and dynamos and boiler seatings and flues, at 8d. per foot, £5,430; five steel boilers, 28ft. long and 7ft. in diameter, for a working pressure of 150lb. per square inch, £2,125; steam main round engine and boiler rooms, with the necessary valves, separators, and drain pipes, £655; exhaust-main, floor plates, and frames, £280; pump injectors, feed-pipes, and connections, £382; blow-off pipes and connections, £65; lagging boilers and pipes

Digitized by Google

with non-conducting composition, £150; one 80-h.p. steam dynamo, £700; one 135-h.p. ditto, £1,075; three 360-h.p. ditto, £6,900; steam and exhaust connections, £195; main switchboard, £600; cables for connecting dynamos to switchboard, £350; meters, £1,650; house connections, £900; motor transformers, £3,200; mains (underground), £14,300; contingencies, £1,043—total, £40,000.

Leeds.—At the meeting of the City Council this week Mr. Hannam (chairman of the Highways Committee) moved a resolution to the effect that upon the Royal assent being given to the Leeds Corporation Tramways Bill the Highways Committee be authorised to accept the following tenders for works in connection with the proposed electrical tramway from Roundhay to Kirkstall:

J. Russell and Sons, for poles and brackets	£3,607	0	0
Greenwood and Batley, for underground conduits and conductors	4,553	1	3
Crompton and Co., for trolley wires and attachments	3,370	0	0
Greenwood and Batley, for electric motorcars	14,000	0	0
Chloride Electrical Storage Syndicate, for accumulators and switches	1,341	0	0
Greenwood and Batley, for steam-engines	3,507	0	0
Greenwood and Batley, for dynamos, etc.	3,200	0	0
Clayton, Son, and Co., for boilers, etc.	1,371	0	0
J. T. Wright, for generating station	5,815	0	0

and that the sum of £3,541 be granted to the committee for foundations for engines and boilers, accumulator stations, fixing poles, etc. Mr. Hannam mentioned that Messrs. Crompton and Co. had withdrawn their tender of £3,370 for trolley wires and attachments, having made a mistake. The Council had therefore no alternative but to consent to the withdrawal. The next tender above it was £5,620, and if that were accepted it would add £2,250 to the estimate. He took it that the Council had no power to dispose of the matter now. It would be dealt with by the committee in the usual course, and would be brought up at the next meeting. He moved the acceptance of the tenders named with the exception of that of Messrs. Crompton and Co. Mr. Henry stated that, with one or two exceptions, the committee were practically unanimous in favour of the Corporation erecting a generating station, instead of taking the electricity from a company. The Corporation, he urged, should take the entire scheme into its own hands, and not allow a company to supply the energy, and thereby increase the value of its plant and enormously increase the amount which the Corporation would have to pay when they bought the concern from the company. Mr. Smithson moved as an amendment: "That, in view of the offer of the House-to-House Electricity Company, Limited, to supply electricity at the rate of 1½d. per Board of Trade unit, the tenders for engines, boilers, and generating station be referred back to the Highways Committee for further consideration with a view to their coming to terms with the company." The amendment was lost, and the original resolution was carried by 44 votes to 8. Owing to the improvements which have been brought about in recent years, the cars will weigh some three tons less than those now running along Roundhay-road. The poles and brackets have been designed by Dr. Hopkinson, the Corporation's electrical engineer, and they will present a decidedly handsome appearance.

Southampton.—At the meeting of the Town Council, Mr. Lemon, in accordance with notice, proposed "That the Works Committee negotiate with the Southampton Tramway Company as to the purchase of the tramways in the borough, and report thereon to the Council." The Tramways Act, 1877, said if the Corporation should apply to Parliament the company should not oppose, but should assent thereto and do everything necessary to obtain the power; but they could not make application for the purchase of these tramways later than 21 years after the passing of the Act. It was therefore absolutely necessary, if the Corporation determined to purchase this undertaking, that they must do so before August 10, 1898, and it would be seen from the Act that it was necessary that the Council should go to Parliament for the purchase, and the terms of purchase should be determined by agreement under the Lands Clauses Consolidation Act. Assuming that they determined to purchase that day, it would be necessary to go to Parliament this year. They must give notice in November, and they would not get the Royal assent till about August, 1897, so that would only leave 12 months to make the necessary arrangements for the working of the tramways. If they postponed action till next year they could not go to Parliament until the following November, and the result would be they could not obtain their powers till August, 1898, which was the time when the Act expired, so that if they delayed for a year they would have no margin to come to an arrangement, and the result was that their powers might lapse. So it was absolutely necessary, if they determined to purchase, that they should go to Parliament in November next. He was not going to commit the Council to an opinion as to the best forms of purchase, but to show the two kinds of purchase adopted in other places. The first was to purchase the permanent way of the tramway only, and lease it to the existing tramway company at a rental, the company to do all repairs, the rent to be paid by the tramway company to be a percentage over and above the amount to be paid by the Corporation to repay the principal and the interest of the loan to be obtained, so that the Corporation would have a profit. That was the principle that had been adopted at Portsmouth. The second mode of acquiring was to go to Parliament, and, failing agreement, to go to arbitration under the Lands Clauses Consolidation Act; but the result would be that they would have to purchase the whole undertaking and work it themselves. He was not going to express an opinion as to the different modes of purchase, but would ask the Council to refer this question to the Works Committee, giving them power to negotiate with the tramway company with the view to purchase. There was an additional reason why they should take action now, and it was because the Corporation had to all intents and purposes purchased the electric light company and no doubt they would get the consent of the Local Government Board—and when the committee put up the standards for lighting the town they should put up such standards as would answer the purpose of putting overhead wires, so as to work the trams by electricity. All these things would have to be considered, so as not to have to do things twice over. He wished members of the Council had gone to Hamburg to see the beautiful way the trams there were worked by electricity. He and others rode round the city and knew how beautifully they worked, and if the Council decided and came to terms to purchase and let the tramways to the company, they could come to terms with the company that they should charge so much per unit for the electric current. The result would be an advantage to the town in every way. If they granted the power to the committee to negotiate it would depend upon what terms they could come to, and if they did not purchase there would be an end of the matter. He did not know the views of the tramway company, but wanted to make enquiries. Senior Bailiff Walton seconded the proposition, stating that the question of the actual terms would be a matter for the committee to consider and report to the Council upon. He believed it would be a step in the right direction whether they leased or kept the tramways in their own hands, but, above all things, the permanent way should be in the hands of the Corporation to carry out the necessary repairs. The proposition was carried unanimously.

Birmingham.—The Public Works Committee have issued their report with respect to the application from Mr. R. Harding Milward, acting on behalf of Messrs William Mackenzie, of Toronto, and James Ross, of Montreal, the president and vice-president respectively of the Toronto and Montreal Street Railway Companies, for the consent of the Corporation to an assignment to them and a company to be formed by them of the leases now held by the Birmingham Central Tramways Company from the Corporation, to the subsequent surrender of such leases, and to the granting to the new company of a new lease or leases of the tramways for a fresh term of 21 years. The total length of line is 27 miles 34.7 chains, and the certified cost is £141,597. 1s 11d. The deposits with the Corporation amount to £68,580. 2s. 3d. The rent for the first 14 years of current leases is £5,663 17s., and for the last seven years £7,079. 17s. The annual sinking fund payment is £4,061. 8s. In addition to the rental, the company pay the actual cost of repairing the tramways, as certified by the city surveyors. In reporting their conclusions on the whole subject, the committee say: "(1) That they have not sufficient experience of the working of tramways by municipalities to guide them as to the probability of the Corporation desiring to take the tramways into their own hands at the expiration of the existing leases; (2) that the experiments being made in methods of traction, autocars, etc., render it desirable that for the present the tramways should continue to be worked by lessees, under such covenants for ensuring cheap and quick transit, and the safety, comfort, and convenience of the public as may be thought necessary; (3) that the Corporation would not be justified in rejecting the immediate and prospective advantages which they and the public would derive from the acceptance of the present offer. The principal advantages to be derived from complying with the request of Messrs. Mackenzie and Ross upon the conditions which your committee have provisionally arranged are: (1) the immediate abolition of steam traction and the substitution of overhead or underground electric or other improved system of traction to be approved by the Corporation, with smaller and more sightly cars, and a quicker and improved service; (2) the introduction of ½d. fares for short distances, and the reduction of fares for long distances; (3) a reduction of the working hours of the men; (4) an immediate increased rental to the Corporation. The profit of the Corporation upon the existing leases is estimated during the remaining portion of the first 14 years of the leases, after paying capital charges, at ½ per cent. per annum on the cost of construction, or about £700 per annum, and during the last seven years of the leases at 1 per cent., or about £1,400 per annum. Under the proposed terms the Corporation would at once receive £5,000 per annum, and a proportionately larger sum if any new lines are constructed, all the capital charges being borne by the lessees. It must not be assumed that the committee are opposed to the principle of municipalisation. They gave full consideration to this aspect of the question, but inasmuch as the present leases do not expire till 10½ and 15 years hence respectively, present municipalisation could only be effected by the Corporation purchasing the existing leases, and expending a very large capital sum in addition for reconstruction, in a similar manner to that proposed by the syndicate. This expenditure your committee could not recommend to the Council, nor, in their opinion, would the Council accept such a responsibility. The alternative then remained of leaving the existing leases in the hands of the present company until their expiration. The adoption of this course offers the prospect of a comparatively limited improvement in the present services and no reduction of fares or of working hours to the men. Your committee believe that by the acceptance of the offer of Messrs. Mackenzie and Ross upon the conditions which have been provisionally agreed, the Corporation and the public will derive all the advantages which they could reasonably anticipate from the working of the tramways by the Corporation, while they will run none of the risks which are

Digitized by Google

inevitably associated with such an undertaking. By adopting the scheme now recommended by the committee the use of steam will be at once abolished, the tramways will be reconstructed without increasing the Corporation debt, a reduction of fares will be secured, a reduction of the working hours of the men will be obtained, and a substantial annual contribution will be made in relief of the rates. These advantages will be at once secured, at the cost of deferring the possibility of the municipalisation of these lines for a period of 10 years. The balance of advantage to the city seems to the committee clearly to lie in accepting the scheme now proposed."

PROVISIONAL PATENTS, 1896.

JUNE 22.

13723. Improvements in and in connection with incandescence electric lamps. Gustav Germer and Friedrich Arno Hüller, 89, Chancery-lane, London. (Complete specification.)

13729. Improved process for telegraphing with Morse apparatus. Luigi Cerebotani and Max Bernstein, proprietor of the firm of Joh. Friedr. Wallmann and Co, 111, Hatton-garden, London. (Complete specification.)

13730. Improved solenoid for electric arc lamps. Moriz Baumer, 111, Hatton-garden, London. (Complete specification.)

13767. Improvements in dynamo-electric generators, motors, and transformers. Eugenio Cantano 45, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents, etc, Act, 1883, Sec. 103, February 11, 1896, being date of application in Italy.) (Complete specification.)

13775. Improvements in polyphase electric motors. Henry Pieper, Fils, 47, Lincoln's-inn-fields, London.

JUNE 23.

13814. Improvements in electric tramways. James Enright, 202, Holland-road, Kensington, London.

13824. A standard of electromotive force or potential difference. Walter Hibbert and Tyson Sewell, 14, Goldhurst-terrace East, South Hampstead, London.

13847. Improvements in and relating to electro-mechanically operated gas-lighters and the like. James Tarbotton Armstrong and Axel Orling, 64, Aldersgate-street, London.

13889. Improvements in and relating to electrical distributors. Louis Kling Oppenheimer, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

13891. Improvements relating to incandescent electric lamps. Cornelis Alewijnse and Roothaan Alewijnse and Co., 322, High Holborn, London.

JUNE 24.

14005. Apparatus for automatically closing and opening by electrical agency the barriers of railway level crossings. Christiaem Cornelius van der Valk, 28, Southampton-buildings, Chancery lane, London. (Complete specification.)

14014. An improved electric cooking and frying or roasting apparatus. George Cecil Dymond, of the firm of W. P. Thompson and Co., 6, Lord-street, Liverpool. (The Chemisch-Elektrische Fabrik "Prometheus" Gesellschaft mit beschrankter Haftung, Germany.) (Complete specification.)

14015. Improved electric heating devices. George Cecil Dymond, of the firm of W. P. Thompson and Co., 6, Lord-street, Liverpool. (The Chemisch-Elektrische Fabrik "Prometheus" Gesellschaft mit beschrankter Haftung, Germany) (Complete specification.)

14020. Improvements in electrically-propelled velocipedes. Clovis Pierre Francis Clerc and Adolphe Georges Pingault, 45, Southampton-buildings, Chancery-lane, London.

JUNE 25

14064. Central battery telephone exchanger system. Daniel Sinclair and William Aitken, 62, St. Vincent-street, Glasgow.

14092. Improvements in electric motors especially applicable to the propulsion of velocipedes and motorcars. Clovis Pierre Francis Clerc and Adolphe Georges Pingault, 45, Southampton buildings, Chancery-lane, London.

JUNE 26.

14157. An improved form of washer for use in connecting secondary battery lugs and other electrical conductors. John Somerville Highfield, 6, Ingestre-road, Stafford.

14187. A portable electric drill. Ernest Holmes and Siemens Bros. and Co., Limited, 28, Southampton-buildings, Chancery-lane, London. (Complete specification)

14197. Improvements in or relating to incandescent electric lamps. Cornelis Alewijnse and Roothaan Alewijnse and Co., 322, High Holborn, London.

14220. Improvements in electrically-heated radiators. William Brooke Sayers, 46, Lincoln's-inn-fields, London.

NOTES.

Obituary.—The death has been announced of Dr. Alexander Stoletoff at the age of 57. Dr. Stoletoff was professor of physics at the University of Moscow and the author of several contributions to the theory of electricity and electromagnetism.

Society of Engineers.—A visit was made by a party of the members of the Society of Engineers on Tuesday to the M. S. and L. Railway extension to London works (Rugby to Byfield section). Among those present were: Mr. W. Worby Beaumont, vice-president; Mr. A. T. Walmisley, past-president; Mr. George Burt, and Mr. Percy Griffith.

Canadian Electrical Association. — The sixth annual convention of the Canadian Electrical Association was opened at Toronto on June 17. The attendance was one of the largest in the history of the association. Mr. A. B. Smith, superintendent of the Great North-Western Telegraph Company, the president of the association, occupied the chair, and delivered the presidential address. The convention lasted three days. Next year it will meet at Niagara Falls.

New Aluminium Alloys.—Mr. Moissan has obtained quite a quantity of new alloys by projecting a mixture of the oxide of the alloying metal with powdered aluminium into a bath of liquid aluminium. Alloys of aluminium with nickel, molybdenum, tungsten, uranium, and titanium have been obtained in this way. An amount of heat is set free by the reaction, but this is probably only due to oxidation of the melted aluminium, and does not necessarily indicate that the alloys are chemical compounds.

Tramways in America.—The Chicago *Electrical Journal* says that one by one, and rapidly, the "cable roads in the large cities" are changing to electricity. But on the same page it is stated that the Nantasket Beach road has abandoned the overhead trolley in favour of the third rail. The opinion of our contemporary appears to be that "the overhead trolley will not do, and the third rail will not do except for elevated construction," but it thinks great things of an underground trolley system, "the so-called conduit."

Electrical Standardising Institution.—As a result of the recent scholarship examination the following awards have been made by the Board of Control of the Electrical Standardising, Testing, and Training Institution, Charing Cross-road, W.C.: to Mr. R. Pearson Russell, of the Royal Academy, Woolwich, a Maxwell scholarship of 50 guineas, tenable for two years; Mr. E. A. Thompson, of Dulwich College, an exhibition of 35 guineas, tenable for two years; and Mr. John Petrie, of Carlisle Grammar School, Mr. H. K. Rodwell, of Felsted School, and Mr. C. C. Hurford, of Epsom College, prizes of 20, 10, and 5 guineas respectively.

Parisian Novelties.—According to the *Revue Industrielle*, an electric boat has been constructed for the purpose of visiting and inspecting some of the large sewers. The boat is warped with a chain which it picks up as it goes along, according to a practice employed elsewhere in France, and the motive power is a Fulmen accumulator battery. Another journal announces that a number of the Paris policemen have been provided with electric "bullseyes." Whether this is done to get an extra powerful light or not is not stated. The tiny incandescent lamp for ticket collectors has been seen spasmodically in London omnibuses and on ticket platforms for some time.

Very Temporary Construction.—The *Times* correspondent with the Soudan expeditionary force, writing from Ferkeh on June 15, says: "At this end the Egyptian and black troops are constructing the railway formation at such a rate that the engineers surveying the line have difficulty in keeping ahead of them. The telegraph wire was brought here on the 10th, and will be at Suarda within a few days. For a great part of the way the non-insulated wire is merely laid on the sand, which in this dry country is an absolute non-conductor of electricity." It would be interesting to have added what is considered "good earth" for such a line—probably water.

Bankside Station.—It may be worth note that the current number of the *Revue Industrielle* begins with a description of the City of London Company's system, with illustrations and plans of the Bankside works. Mention is made of the parallel running that was done with the Wool Quay temporary station. To a foreigner, who would hardly be supposed to know the relations as to area and government of the "City" to the rest of London, the opening words of the article might easily prove misleading. They are: "The city of London is divided for public and private lighting into three districts, of which the most important, the eastern one, is worked" by the company above referred to.

Electric Lighthouses.—In reference to what has been said in previous notes with regard to the "penetrating" power of the Ushant lighthouse and the loss of the "Drummond Castle," it may be worth adding that it now appears, on information derived from the Inspector-General of the French Lighthouse Service, that at the time of the wreck both the Ushant light (electric) and the Ushant Stiff oil light (which is a 22,000-c.p. one) were equally invisible at a distance of three miles. The attempt to use the disaster to the "Drummond" as a means of reviving the controversy as to electric *versus* gas or oil lighting for lighthouses was therefore, as we pointed out the time, quite unwarranted by the probabilities or facts of the case.

Electric Traction.—The French Society of Civil Engineers have been lately much occupied with the question of the possible adaptation of electric traction to railways. The question has been examined from the point of view of obtaining a high speed in a paper read there by Mr. E. de Marchena, who appears to think that the necessary generating stations along the line might undertake other work, such as lighting and power distribution. In the discussion which followed, Mr. P. Villain thought that a trolley system would not do for high speeds, but Mr. de Marchena said it had been used successfully in America for speeds as high as 36 miles an hour. Other speakers suggested that the trolley was capable of modification.

Nijni-Novgorod Exhibition.—The exhibition at Nijni-Novgorod was opened last month. That town is decidedly beyond the range of most European visitors, and there have been so many exhibitions lately that this particular one in Eastern Russia is likely to be very much overlooked. Not because of its smallness—it seems to be big enough, since the area occupied exceeds 200 acres. So far as electricity is concerned, Siemens and Halske and some other German firms are exhibiting. Electrical railways and electrical lighting have been introduced throughout the fair (that there is a fair there is all that most people know of Nijni-Novgorod), and extended between the town and the exhibition. A small electrical tramway has also been laid down in the grounds of the latter. There are also exhibits of electro-bleaching.

Storm at Oxford.—A severe thunderstorm passed over the Midland Counties on Wednesday evening. A good deal of damage was done at Peterborough, where there was an agricultural show going on, and at Oxford the Ashmolean Museum was struck and the roof set on fire. It was half-past six, and there was no one in the building, which was locked up, but fortunately the

Digitized by Google

occurrence was noticed by some workmen, so that the fire was put out before any damage was done to the contents of the museum. Had the storm been a little later, the whole of the valuable contents of the library and picture galleries might have been destroyed. The building has four lightning conductors, but the discharge, instead of going to these, struck a gable, where a lead gutter and standpipe provided a good conductor to earth.

Personal.—The governing body of the Northern Polytechnic (London) has appointed as head of the department of electricity and electrical engineering Mr. V. A. Mundella, B.A. (Cambridge), B.Sc. (Durham), late Pemberton Fellow of the University of Durham. Mr. Mundella for the last five years has been one of the lecturers on physics and electrical engineering in the Durham College of Science, and has had considerable experience in connection with the erection and management of electrical installations. As head of the mechanical engineering department, the selection of the governing body is Mr. Alfred Garratt, of University College, Bristol, and as first assistant in the chemical department Mr. Thomas Ewan, B.Sc. (Vict.), Ph.D. (Munich). Since 1894 Dr. Ewan has been demonstrator and assistant lecturer in chemistry at the Yorkshire College.

University of London.—The Bill appointing a statutory commission to deal with the proposals for making the London University a teaching as well as an examining university, has been introduced in the Lords at last. But its introducer, the Duke of Devonshire, in moving the first reading, made use of the ominous words that he could not form any opinion whether the Bill could pass the other House this session, but he trusted it might at all events be passed by their lordships, and that an opportunity would be afforded for ascertaining the real character of any opposition that might be offered to the proposed change in the constitution of the university. If anything really is to be done—and most people are at least agreed that the present state of affairs is not satisfactory—there seems no particular reason why the Bill should not have been introduced at a much earlier period of the session.

Telephone Troubles.—A week or two ago we acknowledged the receipt from Oskar Leiner, of Leipzig, of a little book by Mr. Arthur Wilke on the "Mutual Influence of Telephone Lines" (Ueber die gegenseitigen Beeinflussungen der Fernsprechleitungen) according to Müller's theory. Müller's theory appears to be that cross-talking and all other telephone troubles arise from deficient insulation, and the use of the wrong sort of insulators. A great deal of space is therefore devoted to possible leakages between insulators on a pole line. The criticisms and objections to the theory that have appeared in the *Elektrotechnische Zeitschrift* and elsewhere are also given and replied to. The purpose of the book may be gathered from its concluding sentence: "But if Müller's theory is proved, the efficacy of Müller's method of prevention is a necessary consequence of that theory, and this theoretical efficacy is confirmed by the experiments described"—but we doubt the fact.

The Civil Pension List.—We are pleased to see in the list of new pensions recently laid on the table of the House of Commons the names of Mrs. T. H. Huxley and Mr. Oliver Heaviside. It is needless to refer to the claim the widow of Prof. Huxley has on the nation, and we are only too pleased to see the value of his life work thus acknowledged. The other recipient, although not equally illustrious, has devoted years of his life to unremunerative physical and mathematical research. Although Mr. Heaviside in most of his writings is unintelligible to the average reader, there is no doubt that he has done much to develop a new system of mathematical treatment which is highly appreciated by those who do understand it. The leaders in all new crusades of this kind which have not a direct application to the pocket of the people are apt to be sneered at by the practical man, and we are therefore exceedingly glad that Mr. Heaviside's arduous labours have been duly recognised.

German Prices for Current.—There is given in tabular form in the *Elektrotechnische Zeitschrift* particulars of the tariff for current at 36 towns. These are mostly in Germany, but Vienna, Copenhagen, Stockholm, and Christiania appear in the list. The figures are obtained from the Association of Delegates of Electricity Works, and relate to the year 1894-95. The usual price for lighting purposes appears to be 8pf. per hectowatt-hour, which is equivalent to something like 9½d. per unit; but heavy rebates are allowed in almost every case, depending on the quantity taken. The way in which these are calculated, however, differs so much that it is hardly possible to summarise them. A brief description of the system of supply is also given, from which it appears that more than three-quarters of the stations are continuous-current ones. It is also worth note that in a very large number of cases the municipality own both the gas and electricity works.

Electric Train-Lighting.—It is stated that the National Electric Car-Lighting Company, of New York, have so far interested the Pennsylvania Railroad Company in their method of railway-carriage lighting as to have got a practical test made by the railroad company on their line. The mechanism and power employed to produce 14 c.p. to 16 c.p. electric lights in railroad trains "is located and produced entirely on the truck of the car. The power is derived from the revolution of the car axles. Storage batteries, which are charged for five hours, but can run for 12, are also placed on the truck." Thus far, 4,000 miles have been covered by trains with this system of lighting, and it is stated on behalf of the National Electric Car-Lighting Company that "the system is coming up to the entire expectations of all parties concerned." If the Americans would use electric lighting and steam heating for their railroad cars, we should hear no more of those terrible fires which are the frequent sequel of a railway accident in the States.

Acetylene Motors.—A paper read by Mr. Ravel before the French Société technique de l'Industrie du Gaz at their meeting at Clermont-Ferrand last month is reproduced in the *Revu Industrielle.* Mr. Ravel has been going into the matter experimentally, and does not appear to think that the new illuminant is going to be any good for motor purposes. If a large proportion of acetylene is used in the working gas mixture the explosion is too violent for convenient use, while if the acetylene is diluted to avoid this the heating power is not what it might be. Mr. Ravel says, "Perhaps this gas will find its application in rotary engines or turbines, but on that path, thorny enough in itself, there are practical difficulties of the first order to be encountered." Why anybody should choose for a motor what is eminently an illuminating gas is not very clear. Moreover, acetylene has to clear itself of the suspicion, whether ill-founded or not, that when under pressure it may explode of itself. Mr. Ravel does not seem to have been quite happy himself on this point when in the course of his experiments he found his generator getting hot.

Water Power.—Commenting on Mr. A. Steiger's paper before the Institution of Electrical Engineers on the utilisation of water power, the New York *Electrical Engineer* says that the popular impression regarding the economy of water power is in very few cases actually

Digitized by Google

realised in practice, or at least the economy is not what it would appear to be considering the energy is supplied free of charge. "It is almost impossible to make any general comparison between the cost of steam power supplied from coal and water power, although this is easily done in the case of any particular plant, but it is well known to engineers that where coal is reasonably cheap and the water power available needs considerable development, the former power is usually the more economical. Where natural conditions, on the other hand, are favourable, water power may offer great economy, but it is not by any means safe to assume this as a general rule." From this it would appear that the ideas on the subject expressed by most of the speakers when the paper was discussed hold good even under the much more widely varying conditions of the North American continent.

Vanadium Carbide.—If Mr. Moissan continues his investigations as to the reduction in the electric furnace of those elements not easily obtainable in the metallic state by ordinary means, we shall soon know precisely the behaviour of all the refractory and rare elements towards carbon. At present there seems to be something like a regular gradation according to Mendeleieff's law. As to vanadium, which occupies an important position in the series, Mr. Moissan says that "vanadium pentoxide, reduced in the electric furnace, gives a metal which always contains an appreciable amount of carbon. If the time of heating is as short as possible, a metal containing only 5 per cent. of carbon can be obtained. By prolonging the time of heating the percentage of carbon is increased to 18·5 per cent., indicating the formation of the carbide V C." This carbide is not attacked by water at the ordinary temperature. Vanadium will form alloys with iron, copper, and aluminium, but not with silver. When all the facts have been ascertained and tabulated, they will probably throw some light on the determining causes of the different properties of various samples of cast iron and steel.

High Temperatures.—There are three ways by which high temperatures may be measured. The first uses an air thermometer of refractory material; the second depends on the change in the resistance of a platinum wire with change in temperature; and the third is based on the employment of a thermo-couple of relatively infusible metals. According to Messrs. Holborn and W. Wien, in a paper published in *Wiedemann's Annalen*, the air-thermometer method was valueless until recently, as suitable vessels could not be made. But now these are produced from refractory clays, and permit of measurements up to 1,500deg. C. (2,732deg. F.). The results are, however, vitiated by the effects of capillarity in the interior of the vessel. The resistance method has also its disadvantages. At high temperatures the resistance generally increases, but the temperature coefficient is irregular. The presence of free hydrogen also affects the resistance. The third or thermopile method is favoured by the authors, who prefer a circuit of platinum and an alloy of platinum with 10 per cent. of rhodium. Temperatures up to 1,600deg. C. (2,912deg. F.) can be measured by it, and it is remarkably constant under various conditions.

Fencing.—The inventor of the new electric "Umpire" is Mr. Muirhead Little, a gentleman who is also known in the surgical world. In spite of its name, the invention is not for use in the cricket field but belongs to the school of arms, and its object is to overcome the difficulty of judging hits in a fencing bout. The end is attained by covering the front of each jacket with fine copper or brass wire gauze and connecting this with the adversary's foil through a circuit containing an electric bell and battery. When a hit is made the circuit is closed and the bell rings. A special arrangement in each foil-handle provides that only a direct point produces a ring. Two entirely electrically distinct circuits are used, one for each fencer, and the arrangements for producing contact are such that flicks, or blows, or grazes produce no result. The bells being of different tones and placed on opposite sides of the room, there is no difficulty in deciding who has scored a hit, or in cases of almost simultaneous hits who delivered the point first. By a simple arrangement the wires passing from the batteries to the combatants' collars are kept well out of the way however sudden may be their movements of advance or retreat. The apparatus has been tried by persons of authority in the fencing world, and there is said to be a complete absence of any restraint on the movements when using it. In spite, however, of a small number of earnest followers fencing is more or less of an exotic in this country. In this matter France sets the fashion, and the use of Mr. Little's invention will have to run the gauntlet of the Parisian schools, where a gibe about fighting at the end of a wire like a marionette on a string might be fatal to the best invention—particularly if it is not of French origin.

Direct-Current Power Transmission. — The electric lighting system of Brescia presents some peculiarities. To begin with, a continuous current at a high voltage is adopted for power transmission instead of an alternating one, and the dynamos are in series according to a practice that has been adopted in other places in Italy. The installation has formed the subject of a descriptive article in *L'Elettricità*, from which it appears that the generating station is at Calvagese, the motive power being derived from the Chiese. There are three 100-h.p. turbines and one of 200 h.p. Each of these is direct coupled to its dynamo. The dynamos are continuous current, and are run in series, and as the smaller machines are wound for 1,400 volts and the large one for 2,700 volts, it will be seen that something not far short of 6,900 volts (continuous) are transmitted over the line. The latter is 22 kilometres (17½ miles) long, and there is a drop of 700 volts. At Brescia the current is converted for purposes of public and private lighting by rotary transformers, of which there are at present six. The public lighting is by arc lamps in series. There are two sets of these, so as to allow about half to be extinguished at midnight. For the private lighting a three-wire system of distribution is adopted. Two batteries of 72 accumulator cells each are used in connection with the three-wire distribution system. The tariff for private lighting is about 6¾d. per kilowatt-hour, but the Government and municipal taxes bring this up to nearer 8d. Motors are provided for in the tariff, and, if used in the daytime only, are granted a reduced rate, but there are no details as to how many of them are in use or likely to be. The electrical part of the work has been done by the Compagnia dell' Industria Elettrica, of Genoa, and the works have been in operation since November last.

The Principles of Price.—Mr. Farnsworth, writing in the New York *Electrical Engineer* on the proper way of charging for electric lighting service, criticises as crude and inaccurate the methods in general use. All operating expenses, he argues, may be divided into three classes, based on the manner in which they could be proportioned among the customers. The first class contains items which should be shared equally by each customer irrespective of size, such as office expenses, meter readings, repairs, salaries, and wages. The second class is made up of expenses which should be divided among the customers in proportion to the size of their equipment, and includes interest, deprecia-

Digitized by Google

tion, energy wasted in transformer cores, and extra labour during heavy loads; and the third class includes coal, oil, waste, ashes, loss in lines, machinery, repairs, and all operating expenses which are a function of the load. Each consumer should pay his proper share of each of the three classes of items, in addition to a certain profit for the company. The first and second classes should form a base-rate, to which is added the charge for current in the third item. All of this would be very nice if everyone was passionately attached to intricate book-keeping and picking out. But even those people who have a fondness for tabulating items have been known to be glad to get others to do the arithmetical work for them, and something very much more rough and ready is necessary for the average householder. Moreover, Mr. Farnsworth's classification would hardly go uncriticised. Why, for instance, should a customer with 10 lamps pay the same share of the "wages, salaries, and repairs" as one with a hundred lamps. Moreover, if you have laid mains for a big customer it is surely good business to get hold of the small customers on the way, even, if taken alone, their service would not have been remunerative.

The Telephone Service.—Letters continue to be published by the *Financial Times* with a view of showing what business men think of the telephone service. The following from "Bishopsgate" is a new complaint: "My companies have recently removed into offices in a large new building here. I have had the telephone for years, and gave orders for it to be removed to the new address. Months have passed, and I find the Telephone Company refuse to reinstate the telephone here because the landlords will not consent to give them carte blanche to erect on the roof of their building a huge structure for the general supply of the company's subscribers. The company evidently rely on their monopoly and the pressure the tenants can put on their landlords to have their own way. Is this business, or fair dealing, with subscribers who have actually paid their rent?" The *Financial News* has also taken up the subject. A correspondent writes: "I have had occasion lately to telephone through to my office from Brighton about 20 times, invariably before 11 a.m., and have never been put through under 15 minutes, and in most cases I have had to wait 25 and 35 minutes before being able to communicate with the office. Then, again, I have what is known as a pass-key, with a number to it, by which I can go to any public call-office, and by quoting the number get through at a reduced price, and yet when I go to the post office they say they know nothing about any pass-key or arrangements, and they want to make one pay the full price. Now, this, to my mind, is very ridiculous, because in the case of Brighton the post office and the telephone head office are in the same street, exactly opposite each other." Another correspondent complains that he can never get on to Kensington from the City under from 20 to 25 minutes, and has been told on more than one occasion that the number required (his own branch office) is not in existence. Further details follow which seem to show that all is not for the best at the best of all possible switchboards.

Carbon-Consuming Batteries.—It will be remembered that some time ago Dr. Coehn obtained what he believed to be a true solution of carbon in hot sulphuric acid, and proceeded to investigate the question whether a carbon-consuming cell could not be obtained in this manner. Dr. Coehn used lead peroxide on the other plate, but the results obtained have been subjected to serious criticism. To some of these criticisms Dr. Coehn has replied in the *Zeitschrift für Electrochemie.* Part of this is concerned in what really happens when an element passes into solution, and has only an inferential bearing on the practical question. Prof. Mendelejeff is quoted as stating that with a weak current through a liquid compound of chlorine and carbon powdered diamond is deposited on the negative electrode, but it is thought that he referred to the work of Despretz, who obtained a diamond powder on a platinum electrode by passing a weak current for two months through acidulated water. He also obtained green crystals on the positive pole by a weak current for six months through an alcoholic solution of a compound of chlorine and carbon, while on the negative pole there was a brown warty substance having the same hardness as diamond. It is also stated that traces of carbon are sometimes contained in the deposited metals in an electrolytic bath. All this, however, only shows what a very long way Dr. Coehn is at present off a practical solution of the problem. With reference to the Jacques hot soda cell, little further has been heard of it except that a company has been or is to be formed to exploit the invention. The American criticisms of it run on the obvious lines, and do not appear to be based on any closer acquaintance with the battery than the descriptions that have appeared from time to time. Of course the first question to determine is whether it is merely necessary to get the soda to a high temperature in order to secure the desired reaction, or whether heat is continuously absorbed from the furnace. The arrangement as it at present stands is obviously capable of improvement should the first supposition turn out correct.

Electrolytic Dissociation.—The *Journal* of the Chemical Society contains two abstracts from the *Zeitschrift für Physikalischer Chemie* which have some bearing on the theory of electrolysis. The first gives the results obtained by Mr. Georg Bredig on the subject of the kathion velocity in the case of the amines. These are closely analogous to those given by Höfker for the mean free path in these compounds in the gaseous state, the latter constant being obtained from measurements of the thermal conductivity of the gases. Both constants decrease with diminishing differences as the weight of the alkyl increases, and in metameric amines are greater the greater the number of alkyl groups united to the nitrogen. The author finds also that the thermal conductivity may be expressed as a linear function of the ion velocity, the observed and calculated numbers agreeing within the limits of experimental errors. The other abstract relates to the influence of electrolytic dissociation on molecular refraction. Messrs. Max Le Blanc and P. Rohland, in order to determine whether the hydrogen ion has a greater specific refraction than that of the combined atom, determined the difference between the molecular refractions of (1) weakly dissociated, (2) strongly dissociated acids and their sodium salts, which are in all cases strongly dissociated. In the case of formic, acetic, glycollic, propionic, butyric, glyceric, and lactic acids the difference in the molecular refractions varied between 3·08 and 3·72 (Gladstone), between 1·56 and 1·80 (Lorenz). For the more strongly dissociated acids, mono-, di-, and tri-chloracetic, nitric, and hydrochloric acids, the differences were 3·17 to 1·37, and 1·60 to 0·75, the number decreasing with dilution and dissociation, so that the hydrogen ion exerts a greater influence than the acid ion. The refraction of sulphuric and tartaric acids were found by Hallwachs to remain almost constant on dilution, a result probably due to the influence of the other ions. Experiments with bases were undertaken, but no similar conclusion regarding the hydroxyl ions could be established.

Motorcarts.—Motorcarts are at present much more talked about than seen, but that is probably inevitable until it is known what will be the final form of the Act to

Digitized by Google

legalise their use on ordinary roads, and whether it will get passed this session or not. Some information as to the progress of the movement in favour of the adoption of these vehicles was given by Sir David Salomons at the meeting of the Self-Propelled Traffic Association on Wednesday. Sir David said that these were early days in the movement, and they would not expect to hear that a great number of members had joined the association, but their success, nevertheless, had exceeded what they had anticipated. They were adopting the principle of having local secretaries to forward their interests in various parts of England, and one, at least, had been appointed in Mr. Shrapnel Smith, at Liverpool. A communication was sent to the French Finance Minister to ascertain what concessions he would make to them for the entry of these carriages into France, and for permitting their reimportation into this country without inconvenience to the users. Information had been sent throughout France to the various Custom House officers that every facility was to be offered to the users of these carriages. No remission could be made in the tax, but on exit the money would be returned without unnecessary formality. The carriage, however, was not to remain in France for more than 12 months. He was anxious to show that they had at heart the interests of the users of these carriages, to make travelling a convenience to them, as well as the commercial side of the question, in bringing purchasers and vendors together. He hoped that the Locomotives on Highway Bill would be passed directly; and that the railway companies would be induced in connection with the movement for horseless carriages to undertake the collection of goods for various stations along their lines. He was a director of the South-Eastern Railway Company, and his colleagues had permitted him to order a carriage in order that an experiment might be made in this direction, and if it answered, he trusted that they would see it extended throughout the country.

Municipal Lighting in Michigan.—It appears from the columns of our contemporary the *Western Electrician* that the State of Michigan is supposed to have taken the lead in municipal lighting in America. As this paper is clearly not in favour of such a policy, which has been so successful in England, it is interesting to note the facts it is able to bring forward in support of its view. The Mayor of Detroit—a Mr. Pingree by name—is credited with the initiation of the policy when stumping the State for "gubernatorial honour." He then told the people that corporations were robbing them. Against the tendency to municipalise the electric light undertaking as advised by the above-named gentleman, the editor quotes the experiences of the Michigan township Marquette. The local conditions at this place were most favourable, and the concession for the use of water power was obtained on most advantageous terms. After this we are informed "it was the old story of political manipulation. The plant was started out with a blare of trumpets, the people were told that they were saving money; the deception was successful for a time, then the true conditions of affairs became apparent, and the city was confronted with the proposition of putting in additional money with the hope of saving, in part at least, the money already invested." Other cities, according to our contemporary, have had similiar experience, and "it is only a question of time when every community in the country that is operating its lighting plant will become convinced that this socialistic feature of city government has proved a costly experiment, and has encouraged and supported a horde of political heelers who could not secure employment with any commercial company." From the above and other statements too numerous to quote verbatim, we gather that the failures in America of municipal undertakings are due to the corrupt practices of the governing bodies. The appointment of an incompetent man because he happens to have influence on the electric lighting committee is the surest way of demoralising the whole undertaking, as the influence of his friends tends to cover up the deficiencies as they arise. We can only trust that the English policy of choosing a capable man, and then trusting him with the whole of the organisation of his department, will always be upheld by our municipalities.

Italian Thunderstorms.—The Roman correspondent of the *Lancet* says that the thunderstorms that have recently visited many of the Italian provinces have done very serious damage to property and occasioned much loss of life. The Ligurian seaboard has suffered exceptionally. "Ball lightning has been witnessed several times, the most dangerous and destructive, fortunately the rarest, form which the 'thunderbolt' is known to assume. Providentially, however, it has this year numbered no victim in Italy. But the ordinary lightning-stroke has caused much loss of life, to say nothing of many grave lesions more or less permanent. Four fatalities are reported from the recent thunderstorm at Genoa, all instantaneous; and at Ventimiglia, in the sacristy of a church, where six priests were assembled, four were killed outright, and the two survivors are in a desperate condition. As a rule, lightning-stroke is most common in the open air, generally under the tree to which the victim has resorted for shelter, and this circumstance, even where only severe injury has been sustained, makes death more likely, as the measures for relieving shock and restoring the vital energies cannot be put in practice till too late. But this year the majority of fatalities from lightning have occurred in dwelling-houses. There is no doubt that for this greater frequency of thunderstorms, as for the more prolonged drought and such like meteorological visitations of latter years, the steady tree-felling, unbalanced by tree-planting, is directly responsible." This account is fully borne out by the reports which have from week to week appeared in *L'Elettricità*, that journal regularly giving a certain amount of space to the subject. It would be interesting to know what authority the *Lancet* correspondent has for considering ball lightning to be particularly fatal. One of the Italian cases happens to have been described in *L'Elettricità*. Two servants were in the room when the "fireball" entered. One ran out, but the other could not. When the ball "exploded" the latter is stated to have sustained a "burn," but was not seriously hurt. The phenomenon is so rare, and the observers are naturally so frightened, that very little is really known about it, and some have even doubted its real existence. Prof. Righi, of Bologna, is stated, by using condensers of great capacity and a large resistance in the circuit, to have succeeded in obtaining a discharge from a Holz machine which would seem to bear the same relation to ball lightning that the ordinary spark does to the "forked" flash. But this is about as far as experiment has gone in the matter, while the theory of the subject is an absolute blank. As to the question of the denudation of the forest land producing thunderstorms, the evidence is very conflicting. The nature of the forest, whether pine, oak, or beech, has probably a great deal to do with it. But obviously in a flat treeless country there will be more fatalities to men and animals than where there are trees or other elevated objects to take the discharge. Consequently a mere counting of accidents is beside the question. Even in classical times Italy was a bad place for thunderstorms.

THE 1896 MEETING OF THE VERBAND DEUTSCHER ELEKTROTECHNIKER IN BERLIN.

(BY OUR SPECIAL CORRESPONDENT.)

(Continued from page 8.)

The first item of the proceedings on Thursday, the 18th, was a short address from the president of the Verband, Prof. Slaby. This gentleman is to be congratulated on the swing which characterised the whole of the business meetings. The purely business matters had been well ventilated by the organ of the society (*Elektrotechnische Zeitschrift*) previously, and so only the vote of the members was required in most cases. In this way much valuable time was saved for the papers in the programme below.

The great difference between the procedure from that common in England lies in the fact that little or no discussion occurred after the reading of the papers. The tendency of the industry in Germany is for the work, and therefore the technical experience to be gathered together is in the hands of a few large firms. Each of these firms has its own expert in different technical branches of the business, and junior employés are hence debarred from giving their opinions. Much the same thing is sometimes found in England to a smaller extent, but our free-lances in discussions are more numerous. In fact, the discussions here can often justly claim to be more valuable to the profession than the papers which cause them. The arrangements at Berlin by which all the illustrations referred to in the papers were usually handed round to everyone present, is of great service when following the gist of the reading. The secretary's and treasurer's reports were both satisfactory, and show that the society is a power in the land, as can be gathered from my interview with Mr. Kapp. The prize for the best design for a non-interchangeable fuse for different currents was awarded to Mr. A. Rittershausen, of Amsterdam. The rules for given and uniform standards for copper to be used for conductors are as follows :

COPPER STANDARDS OF THE VERBAND DEUTSCHER ELEKTROTECHNIKER.

These were embodied in a committee's report on the subject and passed at the meeting at Berlin on June 18, 1896.

1. The specific resistance of conductivity copper shall be given as the resistance expressed in ohms* of a wire of one metre in length and one square millimetre in sectional area at 15deg. C.

2. The conductivity of copper is the reciprocal of the specific resistance set forth in Paragraph 1.

3. Copper of which the specific resistance is greater than 0·0175, or of which the conductivity is smaller than 57, is not to be considered as conductivity copper.

4. By standard copper of 100 per cent. conductivity shall be meant a copper of which the conductivity amounts to 60.

5. In estimating the specific resistance or the conductivity at other temperatures than 15deg. C., in all cases where the temperature coefficient is not separately determined one of 0·4 per cent. per degree C. shall be allowed.

* One ohm = 1·063 Siemens units.

PROGRAMME.

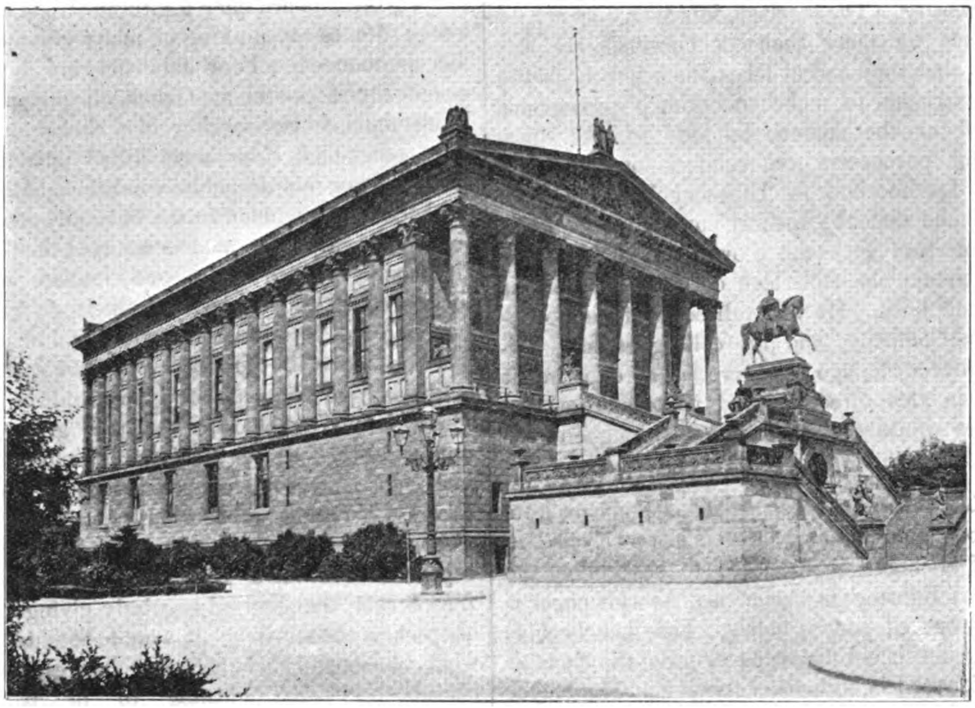
The following is the programme of the business meeting held on Thursday, June 18, at the Architektenhaus :

(1) Presidential address.

(2) Business communications, etc.—(*a*) secretary's report, treasurer's report and estimates, re-election of auditors ; (*b*) reports of committees—(1) on safety rules for electric installations (2) on copper standards, (3) on securing uniformity of contact surfaces and screws, announcement of the award in the non-interchangeable safety fuse competition.

(3) Appointment of new committees.

(4) Papers to be read : (*a*) Director Rathenau, of the Allgemeine Elektricitäts-Gesellschaft, on "The Transmission of Power Works at the Falls of the Rhine" ; (*b*) Director Sarasin on "The Electrical Installation at the Berlin Exhibition" ; (*c*) Dr. Ebeling on "The Magnetic Researches at the Reichsanstalt" ; (*d*) Mr. Bauch on "The Phenomena in the Armature of a Multiphase Motor."



The National Gallery, Berlin.

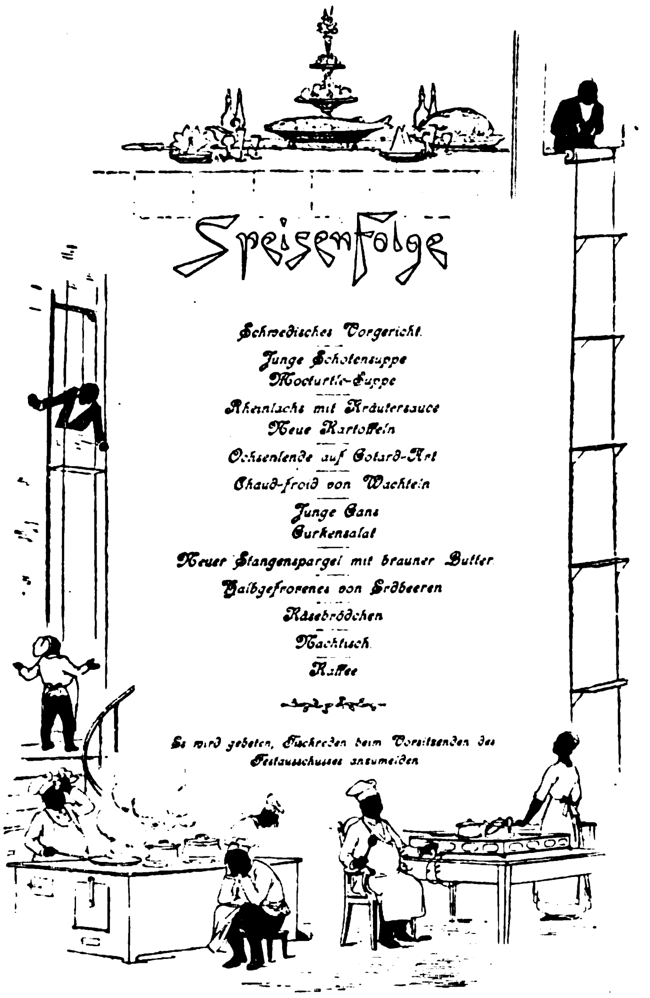
The business meeting was concluded fairly early so that members could get to the dinner at the Kaiserhof by five o'clock. The organisation of the whole of the Berlin meeting was excellent, but of all the events the palm must be given to the dinner arrangements. The menu was not, as is too often the case, the sole recipient of attention, but the general details of decoration and provisions for the comfort of the guests were most complete. The large dining saloon and ante-chamber of the Kaiserhof were chosen as being the best two rooms obtainable in Berlin. These were handed over to a noted firm of decorators about a week beforehand. Under the personal direction of the committee the decorations were then designed to be in keeping with the history of the electric profession. Names of noted men, suitably framed with electric lamps and surrounded by evergreens, were placed round the walls. Hanging festoons of lamps and evergreens were also largely used both in the dining-room and the ante-chamber. Some idea of the effect may be

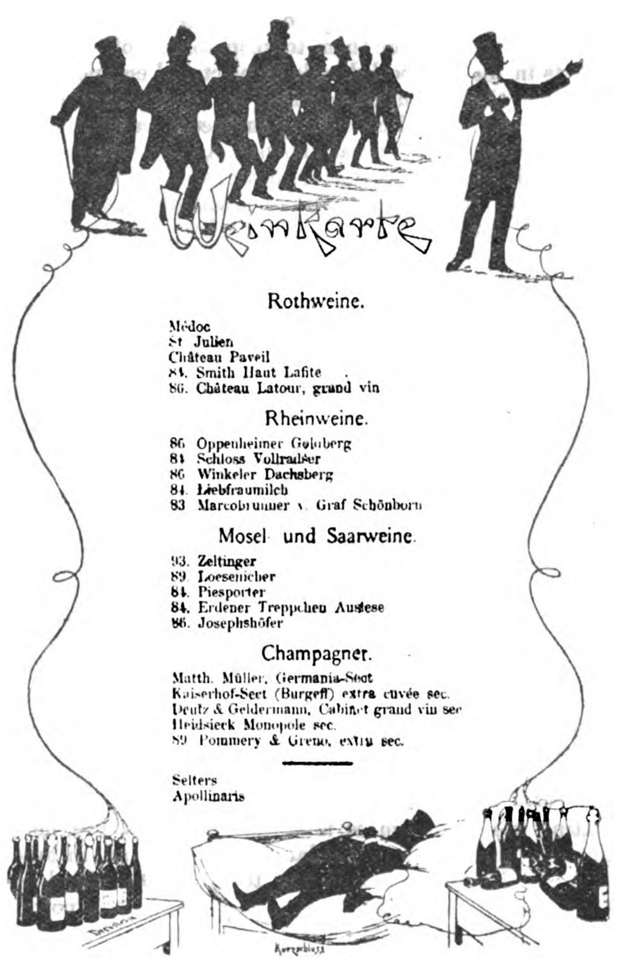
Digitized by Google

obtained from the statement that over 2,000 incandescent lamps were used in the two rooms; all these were installed specially for the occasion, so that the rooms were lighted in a totally different way to that usually seen by visitors at the hotel. The effect of the lamps, backed everywhere by green foliage, was most pleasing, and, although the rooms were brilliantly lighted, the distribution of light was so good that there was no glare.

Every available corner in the room was banked up with plants and flowers. In amongst the foliage electric fans were placed on pedestals of such a height that a current of air was made to pass just over the heads of the guests as they sat at table. The cooling effect of the fans was increased in some cases by placing blocks of ice near them, so that the air drawn into the fans passed over the ice. Vertical pillars of ice at intervals down the tables helped the cooling effect of the fans.

The floral decorations were throughout most profuse, both on the walls and on the tables. The banks of roses given a place of honour between the latter gentleman and the new president of the Verband, Mr. Stubben, of Cologne. The toasts were interspersed between the courses, and the pleasing custom of clinking glass on these occasions gave many of those present the opportunity of drinking wine with their noted visitor. The speeches were short and witty, so that in no part of the evening did the waiting appear irksome. After the menu, as lengthened out by the toasts, had been completed, coffee was served in the ante-chamber, where, amidst palms and large ferns, a number of picturesque nooks were arranged. This afforded an opportunity for many introductions, and also for the renewal of old acquaintances. Mr. and Mrs. Mark Robinson, who had been attending the Naval Architects' meeting at Berlin, were amongst those present, and agreed with me that the evening's entertainment could be copied with advantage by our English society. We also agreed to lay special stress on the additional pleasure afforded by the presence of ladies at





The Menu and Wine-Card of the Dinner of the Verband.

on the high table were specially attractive. As the ladies are always included in such functions in Germany, the guests harmonised with the surroundings, and the colours of the dresses helped to complete the brilliant scene. Each lady as she entered was presented with a handsome bouquet of roses, the colour of the flowers being appropriately selected. Except at the high table, the placing of the guests was left to their individual selection. I was especially fortunate both in the friends who kindly included me in their group and in the position which we occupied. The two partners of the noted publishing firm of Julius Springer and Co. were practically my hosts for the evening, and my enjoyment was due to their kind attention. The guest of the evening was the Viceroy of China (Li Hung Chang), in whose honour a number of Chinese flags were displayed. The Chinese royal standard, a gorgeous production in yellow and black, was hung behind the chair of the distinguished statesman. The son of the viceroy (Lord Li) was also present, and I was pleased to note that Mrs. Kapp was such functions. The band of the Second Regiment of the Guards played in an annexe to the ante-chamber. The two large rooms were connected by a series of lofty arches. The music, although always audible, was not too loud at any part of the large dining-room. One noticeable coincidence in the musical programme was that Li Hung Chang left the room while the "Mikado" was being played by the band.

The menu, with the music programme and wine card attached, gave the committee another opportunity of showing taste in small details. I give with this a reproduction on a smaller scale of the menu and wine card. The illustrations on them need no description, except, perhaps, to state for the benefit of some readers that the word under the reclining gentleman on the wine card means "short-circuit."

Interview with Mr. Gisbert Kapp on the Work of the Verband Deutscher Elektrotechniker.

I found Mr. Gisbert Kapp, the energetic secretary of the

Digitized by Google

Verband, most ready to give me introduction to the leading engineers in the society during the meetings. His time was, however, so taken up with the business in hand that an interview was impossible till the following week. A great deal of the work accomplished by the society can be gathered from the programme of the business meetings, but Mr. Kapp kindly consented to give me further details for the benefit of the *Electrical Engineer* readers.

The object for which the Verband was founded was to unite the whole of the electrical engineers in Germany for the common good of the industry and also for mutual protection. In carrying out these objects the society has also served as a protection to the public, and has had to considerably widen its original programme. Thus, it is now often called upon to give unbiassed reports on technical matters to Government departments and to municipal bodies. Mr. Kapp explained that the state of the consulting engineering profession in Germany was entirely different from that in England. The consulting engineers consist, firstly, of a few high-school professors, who are wholly unbiassed in their advice and who also have great scientific knowledge. Their arduous duties in teaching and in original research, however, take up so much of their time that it is hardly possible for them to keep abreast of the improvements in the practical details of electrical engineering.

After these gentlemen may be mentioned the small number of practical consulting engineers in Germany who, in experience and general knowledge, rank with our leading men in England. They have, however, added a contracting element to their business, now practically extinct in our country. An engineer of this class, when called in to prepare a scheme for electric lighting or power transmission, will not only advise as to the best system and the cost of installing it, but also guarantees that the work can be done for the figure named. If his plans are accepted, he then proceeds to carry out the work himself and to order the necessary machinery personally. This arrangement is apt to lead to the consulting engineer becoming more or less a contractor.

Mr. Kapp then explained to me the usual course adopted by a German town when they require an electric light installation. The town authorities fix the magnitude of the installation they require, and then invite several of the large firms to give them designs and estimates. The tenders sent in of course will differ widely both as regards the system of distribution and the type of plant to be used in the power station. Also, the cheapest tender may in the long run be the least advantageous to the town authorities, on account of the greatest cost of production entailed by its use. In such a case the Verband Deutscher Elektrotechniker is an independent authority to which such schemes may be submitted. Mr. Kapp is usually the adjudicator, but by the rules of the society his advice must only consist in stating which system is most advantageous, and he must not recommend any particular tender. As an instance of this, Mr. Kapp mentioned the town of Dortmund, where they required electric light, and also electric power for driving the cranes at the harbour. The schemes sent in in this case varied very largely. One firm proposed separate power stations, one for each purpose; others proposed three-phase and others direct currents. An independent engineer was therefore necessary to settle the difficulty. Again the advantage of being able to draw information from any member of the Verband gives Mr. Kapp in such cases great advantage in coming to a decision.

In certain great questions of national economy it has become the custom of the country's Ministers of State to consult the Verband. An instance of this occurred at Memel. Here the River Russ forms a delta of very rich soil, which is, however, under water for half the year, and hence useless. As the country round is a most valuable one to the Government for horse-breeding purposes, the inspecting engineer of the district was instructed to investigate the best means for draining this land. He found from experience in the neighbouring districts that the cost of working individual pumps by steam-engines was excessive, owing to the quantity of coal used. He then conceived the idea of using the very best modern steam-engines and of saving the labour expenses of attendance at individual stations by using electrical distribution of power. He submitted his scheme to the Government, who commanded Mr. Kapp to proceed to the spot and investigate the matter. In this case Mr. Kapp reported that the electric distribution of the power would save a considerable sum per annum. The system he advised was a three-phase one at 5,000 volts, and he also pointed out the great advantage of being able to let electric power to the farmers in the summer, when the pumps need not be worked. The electric light would also be of great service when storms damaged the main dyke in winter, as repairs then have to be carried out night and day.

The Verband is also largely concerned in providing for the public safety. It has drafted fire rules, which are universally accepted all over the country. These rules were most carefully drawn up by a committee consisting of representives from every electrical society in the empire, and hence are accepted by all. Over 5,000 copies of these rules have now been bought and circulated, and will tend to that uniformity of practice in installation work so much to be desired. The society has now before it some rules for regulating high-tension systems, and in the consideration thereof will derive great assistance from its Bavarian members, who have had large experience in high-tension work. As an example of the trust the public has in this society, Mr. Kapp told me that the Mayor of Essen, in whose town a 3,000-volt three-phase system was to be installed, asked the Verband to specify the conditions which must be fulfilled to insure the public safety.

MR. GISBERT KAPP, M.I.C.E., M.I.E.E.,
Secretary of the Verband Deutscher Elektrotechniker.

The question of a uniform standard for comparing the conductivity of copper for conductors has also been decided during the past year. The rules prescribed for this purpose I am able to give in full below.

Mr. Kapp then took up the question of the making of laws concerning the electric lighting industry. It seems that the German Government are contemplating the passing of a law making the calibration of electric light meters by an independent authority compulsory. They have asked the Verband to nominate experts to assist the Government to frame this law in a fair and equitable manner.

The last, but not the least, of the objects of the society is that of promoting intercourse both socially and professionally amongst its members. This is being done by the annual meeting which I have had the pleasure of attending. At it papers on subjects of scientific and commercial interest are read and discussed to the mutual advantage of rival firms. Also the social gatherings tend to bring the whole of the leading members of the profession together, and to tone down the discordant spirit engendered by keen business competition. The belief in the good effected by these annual meetings is shown by the generous way in which the Berlin gathering has been supplied with funds. The expenditure in this case has exceeded the income from the sale of the tickets by over £1,000, which

Digitized by Google

sum was largely provided for beforehand by the Berlin banks, who benefit largely by an increase in the prosperity of the industry. The leading electrical firms in Berlin also subscribed handsomely, and the Verband subscribed the rest. The co-operation in this way of rival interests cannot but have a powerful influence for the general welfare.

Interview with Mr. Frederick Drexler on the Recording of Alternate-Current Wave-Forms.

In an interval between the two portions of the programme on the Saturday I had a conversation with Mr. Drexler, who represents the Oerlikon Company at Vienna, about the method he has devised for recording the wave-forms on alternate current systems. Mr. Drexler's object has been to design an apparatus which shall be available for recording the shape of the waves on a commercial electric light system. He explained to me that most of the methods already devised take some considerable time to obtain the correct wave-form. As a rule individual points on the curve are obtained with accuracy, but by the time the points required to complete the wave have been observed the conditions are likely to have altered, unless precautions which can be only used in a laboratory are adopted. Hence, although these methods are extremely good for research work, they are hardly suitable for use on the mains of an electric light station.

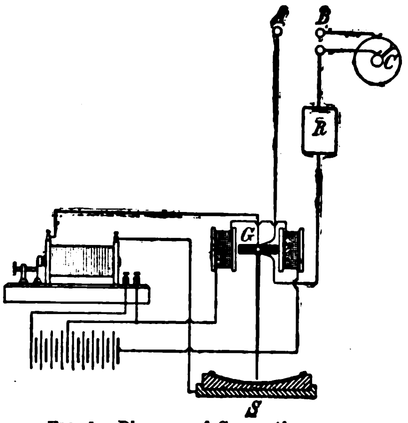


FIG. 1.—Diagram of Connections.

Mr. Drexler's scheme permits of the complete record of the wave-form being taken in under two seconds. The apparatus used is shown diagrammatically in Fig. 1. An electric motor is used, which may be either a direct-current one or a non-synchronous alternate-current motor. The speed of this motor must very nearly coincide with the speed corresponding to the frequency of the system, but it must not quite coincide. On the shaft of this motor is placed an insulated disc having one point of contact on its circumference. The connections between the alternate-current supply and the galvanometer is then completed at intervals by the two brushes shown in the diagram. One of these brushes rests on the spindle of the motor and the other on the insulated disc. The connection is thus made when the conducting point, C, on the disc passes under the brush. If the speed of the motor exactly coincides with that of the frequency of the system, the circuit would always be completed at the same point on the wave-curve.

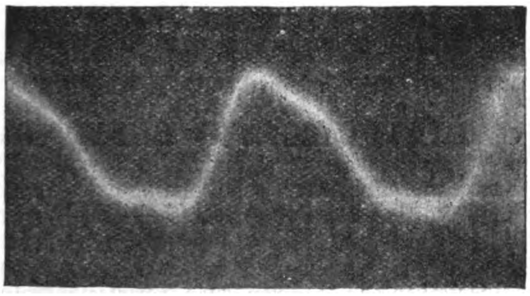

FIG. 2.

The rest of the circuit consists of an adjustable resistance and a Deprez galvanometer, G. The field of this galvanometer is excited by a small battery, and the moving coil is in circuit with the contact-maker described above. The needle, or pointer, of this galvanometer gives a deflection proportional to the voltage applied to it, which varies with the point on the wave at which the contact is made. The effect of the inertia of the moving parts of the galvanometer can be reduced to a minimum by making the difference between the speed of the motor and the natural period of the circuit small. The rate of change of the voltage is then small, and hence, as Mr. Drexler explained to me, the needle of the galvanometer can be relied on to give a correct value. The recording arrangement used by Mr. Drexler in obtaining the curves herewith is also shown diagrammatically in Fig. 1. A sensitised film on celluloid is fixed in a holder of radial cross-section, the radius being slightly more than that described by the end of the galvanometer pointer. The holder has a metallic backing, and a silent discharge from a Ruhmkorff coil is made to pass from the needle through the sensitised plate to this holder. The silver salts on the film are thus decomposed. The film is driven forward by clockwork, so that the discharge traces out on it the form of the alternate-current wave. The three illustrations, which I am able to give by the courtesy of the proprietors of the *Elektrotechnische Zeitschrift*, were all taken on the supply from the Vienna electric light station to Mr. Drexler's private house. They show how greatly the wave-form varies under different conditions of load, and the importance of using a method like the one described, in which the record is obtained in a few seconds. The motor used in the test was a small non-synchronous fan motor. Although a smaller difference in speed could be obtained if a direct-current motor is used, the alternate-current motor has the advantage of automatically following slight alteration in frequency. I understand that Mr. Drexler is arranging the apparatus in a portable form for conveniently testing the wave-forms at any point on the mains. In this case a slightly different form of recorder will be used, as with the present apparatus the test has to be carried out in a dark room. The present form of recorder gives a rather broad outline to the curve, but the breadth is exaggerated by the reproduction. Other methods of tracing the wave shape can, however, easily be devised.

RAILWAY BLOCK SIGNALLING.

BY J. PIGG.

(Continued from page 10.)

Roughly, instruments for block working may be placed in one of two divisions. In the first, the indicating apparatus is stable in either of the positions it can take up, the current is transient, and is only used to effect a *change* of position. In the other division, the indicating apparatus is stable in one position only, and change of position from the normal can only be *maintained* by a continuous current.

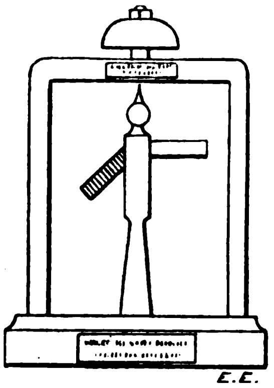

FIG. 3.—Walker's Block Indicator, One Wire.

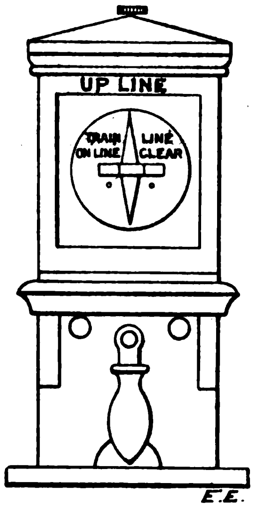

FIG. 4.—Single-Needle Block Indicator, Three Wires.

An example of instruments of the first division may be seen in the block instrument invented by the late C. V. Walker (Fig. 3), which was at one time in general use on the old Stockton and Darlington Railway, now a division of the North-Eastern Railway, and is still to a limited extent. This instrument was also in use on the South-Eastern Railway, of which Mr. Walker was at one time the electrical engineer. A further example of this class of instrument, but of different construction, is the one-wire needle instrument of Tyers (Fig. 5) now in use on the L. and N.W. Railway.

Examples of instruments of the second division are furnished by the single-needle three-wire block instruments in use on the North-Eastern, Great Northern, Midland, L. and N.W., and other railways (Fig. 4).

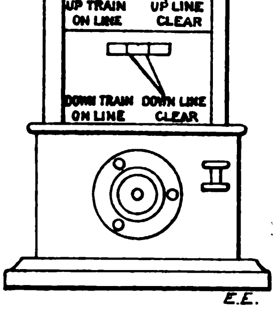

FIG. 5.—Tyer's Block Indicator, One Wire.

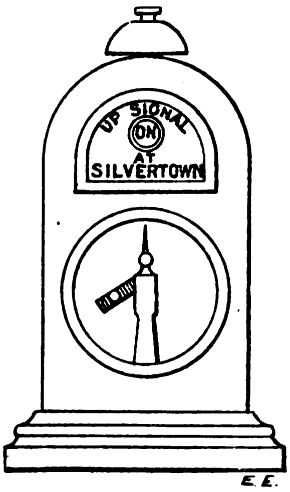

FIG. 6.—Preece's Block Indicator, One Wire.

Instruments of the first division indicate two conditions of the line only—viz., "Line clear" and "Line blocked," or "Train on line." Instruments of the second division indicate three conditions of the line—viz., "Line blocked" (the normal position), "Line clear," and "Train on line." The difference just shown may seem to be of minor consequence, but it is, in reality, of the first importance to the proper indication of the exact position of affairs at any stage of block working. "Line clear," with instruments of the first division, indicates that there is no train in the section of line to which the instrument refers. With instruments of the second division, however, it not only indicates that there is no train in the section, but also that the signalman at the receiving end *has given permission* for a train to be sent forward, and *has made* preparations for its arrival.

As an illustration of the difference in working with the different classes of instruments, the following extracts from the regulations setting forth the methods of working are given:

"Prior to the despatch of a train from A, the signalman there, provided he has received the 'Train out of section' signal for the previous train, and the block indicator is in its normal position, must call the attention of B, and having obtained it, must give the proper 'Is line clear' signal; if the line be clear at B, the signalman there *must acknowledge the signal by repeating it.* The signalman at A may then, if the line is clear, take off his signals for the train to leave A.

"On the train leaving A, the signalman there must send the 'Train entering section' signal to B, and the signalman at B must acknowledge the signal by placing the block indicator to 'Train on line.'"

"Prior to the despatch of a train . . . from A, the signalman there, provided he has received the 'Train out of section' signal for the previous train, and the block indicator be in its normal position, must call the attention of B, and, having obtained it, must give the proper 'Is line clear' signal; if the line be clear at B, the signalman there *must acknowledge the signal and peg the block indicator to the*

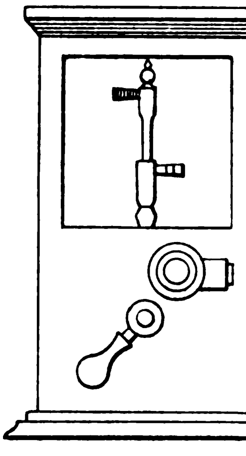

FIG. 7.—Hodgson's Block Indicator (Saxby and Farmer's Lock and Block), One Wire.

'Line clear position.' The signalman at A may then, if the line is clear, take off his signals for the train to leave A. On the train leaving A the signalman there must send the 'Train entering section' signal to B, and the signalman at B must acknowledge the signal and peg the block indicator to 'Train on line.'"

The first of these quotations represents the mode of working a single-wire system with instruments of the first division. In this case the signalman at the sending end has nothing to remind him that he has or has not obtained permission to send a train forward to the advance cabin, and the signalman at the receiving end has nothing to remind him that he has given or not given such permission. In both cases the signalmen have to rely on their memories or their booking for reminders of the "Is line clear" signals that have passed between them.

The second quotation is for a three-wire system, with indicating instruments of the second division. In this case the "Is line clear" signal and its acceptance by the signalman at the advance cabin is recorded at both ends of the section until the permission has been acted upon, and the "Line clear" indication is superseded by "Train on line."

With either class of instrument the line is considered "blocked" until permission is given by acknowledging, by repetition, the "Is line clear" bell signal, but the fundamental difference between the two modes of working is the ability, with instruments of the second division, to record the acceptance of the "Is line clear" signal, so that the

Digitized by Google

signalmen at both ends can, from the indications of their respective instruments, obtain reminders of the signals that have passed and the position of the line at any time. Obviously, the condition of a section cannot be the same after permission has been given to forward a train as before that permission was given, even if the train has not actually entered the section. The acceptance of the preliminary "Is line clear" signal indicates that the line is clear to the advance cabin, that previous trains are fully protected by signals, and that no operations involving the fouling of the line will be undertaken at the advance cabin until the train accepted is clear. Hence, it would appear that instruments of the first division fail to take cognisance of what is without doubt an important condition of the line. How important it is that the operations of the two signalmen, who must necessarily co-operate in the working of traffic, should be perfectly synchronised need not further be commented upon.

Generally, it may be said that instruments which require only one line wire for all the operations involved in double-line block working are those which use transient currents only, whether employed as train-distinguishing signals or as indicators, since the line may be required for the former signals whilst the instruments are indicating "Train on line" for one or other of the lines of rails for which it is used. Conversely, it may be said that instruments which require continuous currents for the maintenance of their

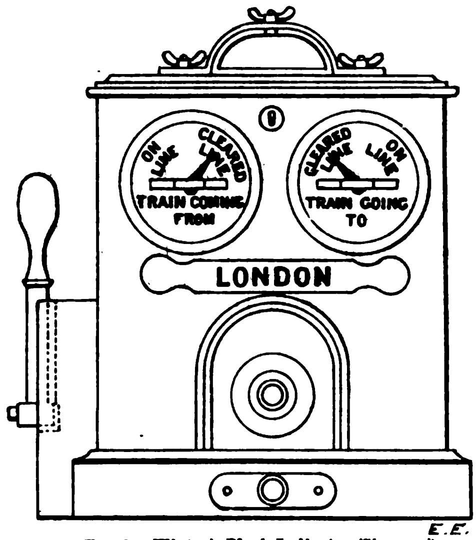

FIG. 8.—Winter's Block Indicator (Siemens').

indications are those which will require three wires, since the indicators must work independently of each other and of the bell signalling apparatus.

From what has been said it follows that the number of independent batteries required will be less for instruments of the first division than for those of the second division, since under actual conditions of work currents are not likely to be used in any one cabin in both directions simultaneously. Where transient currents are used only, the number of batteries required may be reduced to the number of operations that may be carried on simultaneously. With instruments using continuous currents for maintaining the necessary indications, the number of independent batteries required will necessarily be greater owing to the greater number of operations which may require to be carried on at the same time.

It would therefore appear that block instruments using transient currents, and requiring not only one line wire but a smaller number of independent batteries, would be preferable considered from an economical standpoint. Against this advantage it is urged that cutting down the line wire to one, and reducing the battery power to an absolute minimum, is an operation of the nature of putting too many eggs in one basket. If a fault occurs on the line wire, both lines of rails are affected, and must be worked at "Caution" until the defect is removed. If the telegraph lineman is not immediately available, the disorganisation of traffic may be considerable.

On the other hand, with instruments of the second division, a failure of one line wire affects that instrument and the line it represents alone, the other line being worked as usual. It by no means follows that the number of line faults on a three-wire block will be three times that on a one wire.

An important point in connection with the class of instrument most suitable for block working is the indication the apparatus will give when, through a defect, the instruments are not available for use. With instruments of the first division the indication will remain in the position it happened to occupy at the time the defect occurred. This may be either "Line clear" or "Line blocked," according to the condition of the line at the time. With instruments of the second division, where any indication other than "Line blocked" is only maintained by the use of a continuous current, a defect of the line wire or battery will at once cause the indicators to show "Line blocked."

When a defect arises in the block apparatus for any section, involving the suspension of block working, the ordinary space limit is replaced by a time limit, and every train which is sent through that section must be first brought to a stand and the officials in charge of the train advised of the breakdown and instructed to proceed cautiously. Practically, the section of the line where the failure exists is treated as if blocked on the *approach* of any train which may require to pass through that section. With instruments of the first division the indications of the faulty block instruments may, or may not, correspond with the theoretical condition of the line; with instruments of the second division, the defect ensures the indications being such as will correspond with the conditions under which the line is being worked. Instruments of this class may therefore be fairly considered as more reliable under the conditions cited than those of the first division, and the indicators have the further advantage of being self-testing to a large extent when in use.

LECTURE XXXII.

(Specially Contributed.)

Magnetos for Bell-Ringing.—Batteries may with advantage be replaced by magnetos whenever the signalling circuit has a high resistance. The latter cost little for maintenance or inspection. There are no troublesome fumes nor dangerous acids to work with, though the initial cost is greater. When batteries are used with high-resistance circuits, the current from the primary battery is often too feeble to work the apparatus, and a

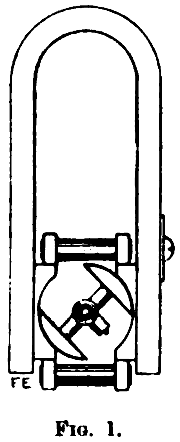

FIG. 1.

supplementary piece of apparatus—the relay—is brought into the circuit. This is merely a means to enable the current of the first battery to close the circuit of a second battery, and to enable the current from the second battery to actuate the required apparatus. The use of a magneto usually avoids the necessity for a relay. These several advantages have led to the almost universal adoption of magnetos for telephonic work, and it is in this connection I shall give a brief description of the apparatus. The particular apparatus

Digitized by Google

described is manufactured by the Western Electric Company. It is known as the bridging bell, and has been designed to permit of several instruments being connected in parallel on the same line. It is necessary to say this because other manufacturers modify the design. The armature of the magneto is of the Siemens shuttle-wound type, as shown in section (Fig. 1).

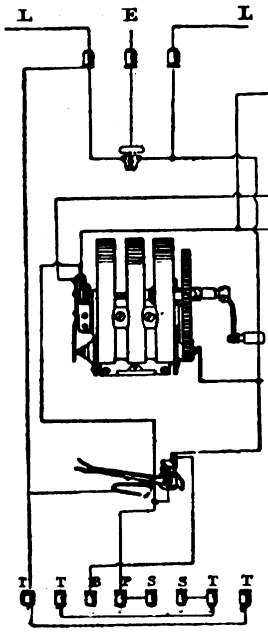

FIG. 2.

The field magnets are three strong permanent magnets of horseshoe type. The armature is revolved by means of a toothed wheel of large diameter engaging a toothed wheel of smaller diameter, as shown in Fig. 2. The magneto, or, as it is usually called, the generator, will ring its own bell through a resistance of 15,000 ohms. A little consideration will show that in an ordinary telephonic circuit there must be instruments—say, bells—at the receiving and at the sending ends, and the coils of both armatures would in the simplest form of circuit be in the circuit, in addition to the coils of the electromagnets attached to the bell. Thus, besides the line wire connections, we have the two armature coils and the two electromagnet coils, the whole giving a very high resistance. In

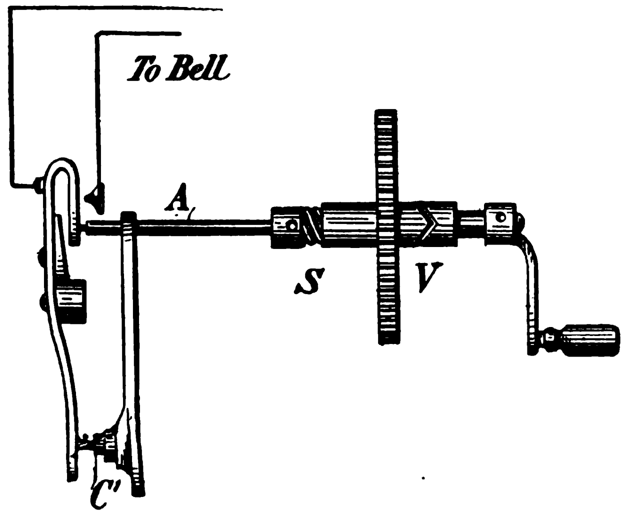

FIG. 2A.

order to decrease this line resistance, as we may call it, efforts have been successfully made to cut out the resistance of the armature coils when receiving, leaving in the line circuit the armature coils only of the sending instrument, and when sending to cut out the coils of the sender's bell. Very ingenious are the various automatic switching arrangements for this purpose. The switch used with the apparatus (Fig. 2) is known as the Chicago switch. Fig. 2A shows more clearly the action of this switch, C_1 showing end of armature spindle. The contacts are made of platinum to avoid oxidation, and are rubbing contacts for cleanliness, and have strong springs to ensure good contact. The driving spindle of the generator, by means of a V working in a slot at the right-hand side (Fig. 2), has a straight movement to the right when the handle is turned, and this motion actuates the automatic cut-out at the left of the generator. When the generator is at rest, the bell coils are in circuit to receive any signals from other stations while the armature coils are cut out, thus saving about 500 ohms—the resistance of the armature coils—in the working circuit. When the handle of the generator is turned, the armature is in direct connection with the line, and the instrument bell is short-circuited, saving a resistance of 1,000 ohms, which is the resistance of the bell coils. The external connections of magneto shown in the figure are: L L, lines; E, earth; A B, auxiliary bell, which is also of 1,000 ohms resistance; T T, receivers; B, one pole of transmitter battery, the other being connected direct to primary of induction coil; P, other end of primary

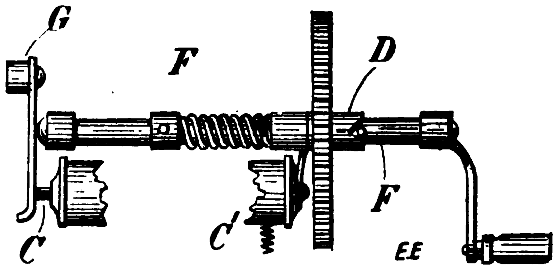

FIG. 3.

coil; S S, secondary winding of induction coil. This instrument will efficiently work up to 10 instruments in parallel. Fig. 3 shows an old form of cut-out. C C_1 show connections to armature, C to a contact-piece, C_1 to spindle, D is the notched hub of wheel; there is a pin gearing into the notch D, while F is a collar on the

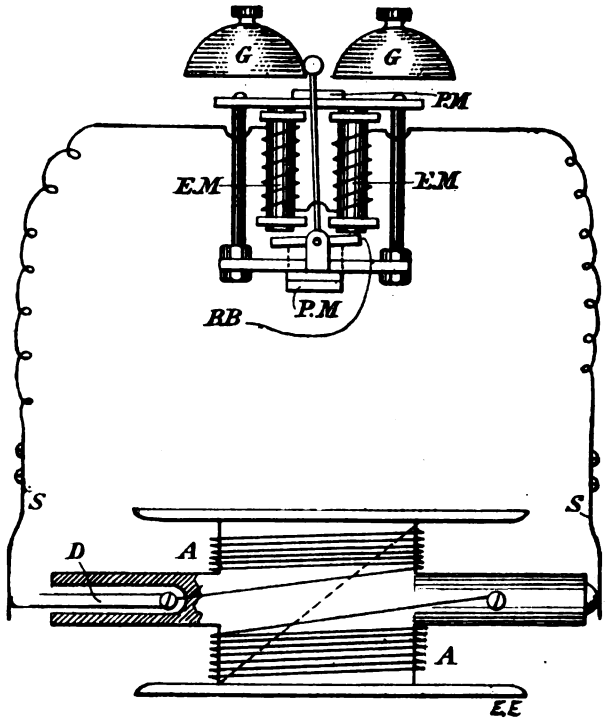

FIG. 4.

spindle holding one end of spring, as shown. This spring holds the pin against one end of slot, making a good contact between the spindle and spring G, short-circuiting the armature coil, which is connected to the spring G and the wheel. When the handle is turned the pin is moved forward to the other end of the slot, moving the spindle to the right hand, and as long as the handle is turned the spindle is held in that position, breaking the short-circuit, and putting the armature coil into the working

Digitized by Google

circuit. Fig. 4 is a rough sketch showing the connections between magneto armature and bell. Here A A represent armature coils; S S, spring contacts carrying current to line wire and return; E M, E M, the bell electromagnet; P M, P M, the ends of the bell permanent magnet; B B, the soft-iron armature; G G, the bell gongs. There are two gongs, because the current being alternate causes the attraction of first one and then the other half of the soft-iron armature, B B, and first one, then the other, of the gongs is struck. A permanent magnet, P M (Fig. 4), and shown in section (Fig. 5), is used in these bells, the lines of force acting

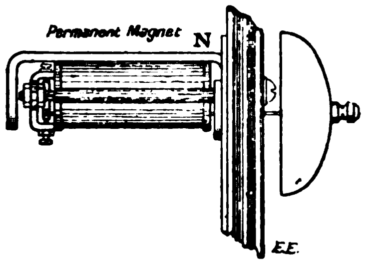

FIG. 5.

on the cores of the electromagnet, and so arranged that a bias is given to the soft-iron armature towards one pole of the electromagnet, and hence to the striker towards one of the gongs. The efficient action of the bell depends largely on the adjustment made by the use of this permanent magnet. As I have previously said, with the exception of their use in telephonic work for the bell signalling circuits, magnetos have practically gone out of use and given place to dynamos, and these we must now examine at some length.

JOHNSON AND STEELE AUTOMATIC POTENTIAL ARRESTER.

The instrument illustrated below (Fig. 1) is the invention of Mr. L. J. Steele. It is practically a lightning arrester, to be used for comparatively small potentials, such as are likely to be found when the shunt circuit of a dynamo is broken. The device consists of two carbon discs mounted side by side on a slate base. These discs are pressed towards each other by springs, but between them is interposed a strip of mica, which, not being so wide as the faces of the discs, leaves a small air-space between them. The air-gap thus secured can be regulated by varying the thickness of the mica, so that the potential at which the spark will pass between the two discs may have any predetermined value.

A safety fuse is placed in series with the arrester, as shown in Fig. 2, which, in case of a permanent circuit being established between the discs, will give way, and thus prevent short-circuiting the field coil, when the current is afterwards switched on again. The discs can be turned on their axes, so as to present towards each other fresh portions of their peripheries after a spark has passed.

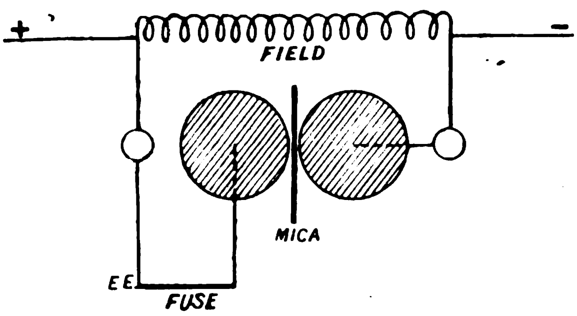

FIG. 2.—Connections for Potential Arrester.

Metal scrapers are also provided (Fig. 1) that bear against the edges of the discs, and clean them as the discs revolve.

The great use of this device is for preventing the rise of pressure on breaking the exciting circuit of dynamos and alternators from injuring the insulation of the field coils. A simple calculation will show how great this potential may be, and it is no uncommon occurrence for a shunt coil to be connected to the frame by the discharge. With the above device the spark-gap between the carbon plates takes the discharge, the connections used being those shown in Fig. 2. The spark at the disc persists till the field has died away. This, in some cases, takes some considerable time. Thus, when breaking the field circuit of large multipolar machines or alternators, the spark is seen to last as long as 20 to 30 seconds.

The apparatus is manufactured by Messrs. Johnson and Phillips, who have supplied a large number of sets, which have, we believe, given every satisfaction.

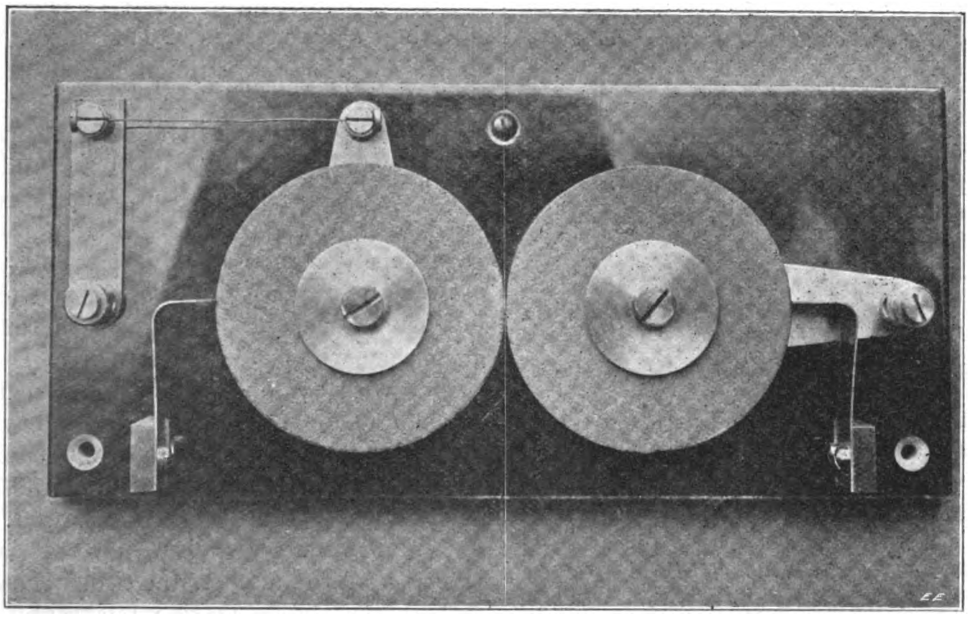

FIG. 1.—View of Johnson and Steele's Potential Arrester.

Royal Institution.—At a general monthly meeting of the members of the Royal Institution on the 6th inst., Sir James Crichton-Browne, M.D., LL.D., F.R.S., treasurer and vice-president, presiding, the Right Hon. Lord Windsor, Mr. Herbert Page, F.R.C.S., and Mr. Alfred Suart were elected members.

THIRTY YEARS OF CABLE WORK.

Sir John Pender is dead. Thirty years ago this very month England and America were on the tiptoe of expectation. Attempts had been previously made to connect these opposite Atlantic shores by means of a submarine cable. These experiments had been eminently successful failures. We use these words advisedly, because the failures taught the way to success; and it was in July, 1866, that the first Atlantic cable was laid that did not break down directly. Subsequent to the successful laying of the 1866 cable, the 1865 cable was picked up and repaired, since when the Old and the New Worlds have never ceased to be in telegraphic communication. Thirty years is not a long period in the pages of history, but during the past thirty years the world has been so connected by cable links that almost instant communication with the Antipodes has ceased to excite surprise. The veriest street *gamin* looks upon it as a matter of course, presenting nothing extraordinary to his mind, being merely an incident in daily life just as eating and drinking. In 1858 the first attempt was made to connect telegraphically Europe with America. The cable manufactured for this experiment had for conductor a copper strand consisting of seven wires (six around one) and weighing 107lb. per nautical mile, the insulation consisted of guttapercha laid on in three concentric coatings and weighing 261lb. per nautical mile, the whole being protected with eighteen strands of iron wire (each of these eighteen strands consisting of seven wires) laid spirally round the core with a padding of tarred hemp between the core and the protector. The weight of the cable in air was 20cwt. per knot, and in water 13·4cwt. The length of cable shipped was 2,174 knots. As we all know, the 1858 experiment ended in failure, and then came the tug-of-war. It was comparatively easy to obtain funds in the first place. Shorter cables were doing good work, and everybody hoped for success with the Atlantic cable. Cyrus Field took up the matter, and impressed his views upon business men in America and in England. It was an arduous task, but in the long run was destined to succeed. Here and there he met with enthusiasts who gave their support. Here and there he met with long-headed business men who could see money in the undertaking and who felt convinced that if a mile of cable could be made to work, so could ten, one hundred, or a thousand miles. And they were right. The late Sir John Pender was one of the business men who took up the matter, and from these early days in the history of submarine telegraphy to the time of his final illness he was a prominent figure in all that concerned cable work, and, with his friends, controlled a large part of the cable network of the world. But to go back. We have given a brief specification of the 1858 unsuccessful cable—we may therefore venture to give a similar account of the successful 1866 cable, which, again, was very similar to the 1865 cable, which in 1865 was lost and in 1866 was found and spliced. The conductor of the 1866 and 1865 cables was a copper strand of seven

Digitized by Google

wires, weighing 300lb. per knot, embedded in Chatterton's compound; the insulator was four coatings of guttapercha interlaid with four of Chatterton's compound. The protector of the 1866 cable differed somewhat from that of the 1865. It consisted of ten wires of homogeneous iron, each wire first galvanised and then bound with five strands of white Manilla yarn, the ten wires wound spirally round the core with an intermediate padding of saturated hemp. The weight of the cable in air was 31cwt. per knot, in water 14·75cwt. It had a breaking strain of 8 tons 2cwt., and would bear its own weight in twelve miles depth of water. The length shipped to lay the 1866 cable and splice the 1865 cable was 2,730 knots. It was on Sunday, July 1, 1866, that the "Great Eastern" left the Nore. The shore end was laid from the "William Corry," and on July 13 the "Great Eastern" began her work, and on the morning of the 27th sighted "Hearts Content." On the 28th the shore-end splice was finished, and the New World was in electric connection with the Old. The first message after testing was to Lord Stanley, the Foreign Secretary, and the Queen from Osborne sent a congratulatory message to President Johnson. On August 1 began what may be termed the real working life of the cable—that is, it was opened for the transmission of ordinary business messages. Just one more reference to the 1865 cable. After considerable trouble and anxiety it was grappled, and on Sunday, September 2, 1866, the end was on board, and the tests showed conduction and insulation all right. The new piece was spliced to the submerged cable, and the "Great Eastern" headed once more for Newfoundland, which was duly reached on September 8, a splice made with the shore end, and two cables at work. As we have said, the late Sir John Pender took an active part in all the financial and business proceedings in connection with this work, and devoted the last thirty years of his life to the development of submarine telegraphy. It needs but a few thoughtful minutes to realise what submarine telegraphy has done for the world. It has in a measure annihilated time and space. It has made commercial transactions easier, and one of its most far-reaching properties has been to practically double the value of capital. Many financiers and statisticians talk learnedly about the appreciation of gold, but they seldom discuss the causes which have led to the appreciation, not the least of which has been the extraordinary development of submarine telegraphy.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ELECTRIC DRIVING POWER.

[For some years we have contended that electrical manufacturing firms ought to do a very large business in arranging motors for printing offices. We are glad to see some correspondence on this subject in one of the trade papers devoted to the printing industry, the *British and Colonial Printer and Stationer*, and no doubt a little concerted enterprise between supply stations and manufacturers ought to enable a good footing to be established in this direction. We give the correspondence herewith.—Ed. *E. E.*]

Sir,—I read with much interest your remarks on the application of electricity to the driving of printing machinery. Many years ago I came to the conclusion that to drive from shafting was a great mistake. Against the advice of the makers of a new rotary web-printing machine I had a direct-acting engine made for it. Driving direct in that case convinced me that it was the right thing, and I have since had all our machines driven by separate engines. The result is that they can be worked to much better advantage, and with a great deal less waste. I have now had several electric motors introduced. One drives a small flat machine, and as the machine is only used at intervals for a few hours a day, I find electricity in its case very handy, and not very expensive. For steadiness electricity beats steam and gas, and there is no trouble whatever in starting or stopping at any moment, as the power is always at command. I have electric motors driving an installation of 10 Linotype machines, and find that although the cost may be a little more there is full compensation in being able to get the machines to work at any moment in case of emergency. The great drawback to the general introduction of electricity is the expense of turning out already existing plant which does the work, although in a more clumsy way. For anyone going in for extension or new premises and plant it would be, in my opinion, sheer foolishness not to adopt the electric motor.—Yours, etc., Scotus.

Edinburgh, June 27th, 1896.

Sir,—I have read your "London Letter" in your issue of the 25th inst., on "A New Adaptation of the Electric Motor," with much interest, and with a view to further ventilating the subject have pleasure in giving you particulars of our installation.

The question as to the best means of transmitting power to machinery placed in various but adjoining buildings arose when we (Bemrose and Sons, Limited) decided to build an extensive addition to our works, comprising some 14 large rooms in all, and after thoroughly investigating the matter, we decided on motors as being the most suitable; economy, convenience, cleanliness, and, we expect, durability, being amongst the advantages.

The result of this decision being that we ordered a complete installation of two dynamos of about 100 h.p. each—already having one of about 40 h.p.—and some eight to ten motors as a start. We have now the first motor actually at work—driving four printing machines (two quad demys and two double royals)—and we are exceedingly pleased with the result. After careful consideration we decided to group our machines, of four or six to a motor, and this is where our system differs from that suggested in your article—in the latter case you certainly do away with some friction on shafting and belts, especially when all the machines in the group are not working, but the saving is infinitesimal, as I think it will be found advisable, even if not absolutely necessary, to have each motor connected by a countershaft and belts (even if driving a single machine), as even low-speed motors are much too fast for direct coupling; and it should be borne in mind that the slower the motor's speed, the larger and more expensive it becomes, and consequently more difficult for convenient direct attachment. Now, on the group principle there is the same saving of power, as the motor only consumes the actual amount of E.M.F. required to do the work placed upon it, and this is proportionate to the number and size of machines actually running; further, we were advised that a greater efficiency is obtained from, say, a 6-h.p. to 10-h.p. motor than from a 1-h.p. to 2-h.p. one, and there is less proportionate expense in the wiring, switches, etc., apart from the saving in the initial cost of the motors.

We expect to derive considerable advantage, seeing that it is so handy to place motors either in the basement or fourth or intermediate floors, and that future extensions in machinery can be dealt with (providing arrangements are made on main switchboards, etc.) irrespective of existing shafting, motors, etc. Our installation will include a special

Digitized by Google

motor for driving a goods lift, and two for driving ventilating fans; the dynamos are so arranged that one or two can be driving the machinery, whilst the third is lighting some 1,000 to 1,200 16-c.p. lamps, besides arc lamps for photographic studio purposes.

We are not yet in a position to make any tests as to relative cost of driving—in fact, it will be very difficult to arrive at, seeing that the same engine drives the old portion of our works by shafting as well as the generators. Nor have we yet been able to test the relative steadiness of the driving, but as the speed of the motors can be adjusted by the resistance switch, we have good reason to believe that we shall have greater facilities as to regulation of speed (which can be purposely altered to suit the work in hand) than with shafting.

I venture to think that by the time we have completed our installation that we shall have given the question a thoroughly practical test such as you suggest, and I shall have much pleasure in showing the same to you.—I am, Sir, yours, etc., W. WRIGHT BEMROSE.

Midland-place Printing Works, Derby, June 27, 1896.

TRANSFORMER SUB-STATIONS AT READING.

The transformer sub-stations fitted up at Reading by Messrs. Paterson and Cooper are good examples of the most recent practice in this direction. When deciding upon the arrangement of these stations, the Reading Company decided that they should be erected above ground, instead of being underground chambers. There are at present two stations, the one in Friar-street being erected specially, and having the whole of the apparatus contained in one room on the ground floor. For the other station in West-street a small cottage has been utilised, the transformers being placed in watertight cases in the cellar, and the switchboards, etc., in the room above on the ground floor, the upper floor being cut away and fitted with skylights.

graph of one of the high-tension boards complete, with the front slate panels removed. Fig. 3 shows in section the construction of the board. There are five switches on the board, one receiving the full amount of 60 amperes from the high-tension mains, and the remaining four carrying 15 amperes each for the transformers. Each switch is double-pole, and for each pole provision is made for a short-circuiting plug. An ampere-meter is placed at the top of the board, and is provided with a short-circuiting plug in

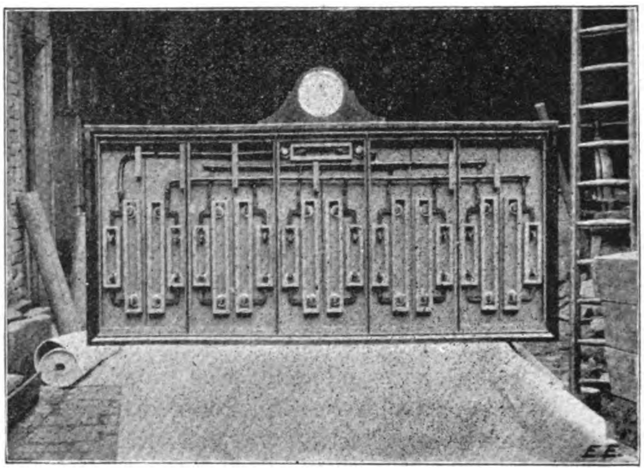

FIG. 2.—High-Tension Board, with Front Panels Removed.

case it is desired to disconnect it. The whole of the current-carrying metalwork is mounted on porcelain insulators fixed to the back slate. The board is framed in teak, and the front closed with enamelled slate panels, having slots through which the switch blades pass. Thus there is absolutely no exposed metalwork at the front of the board, while at the back the only pieces of metal coming through are the terminals, and these are boxed over to prevent accidental contacts. Each switch consists of a pair of knife blades, which slide

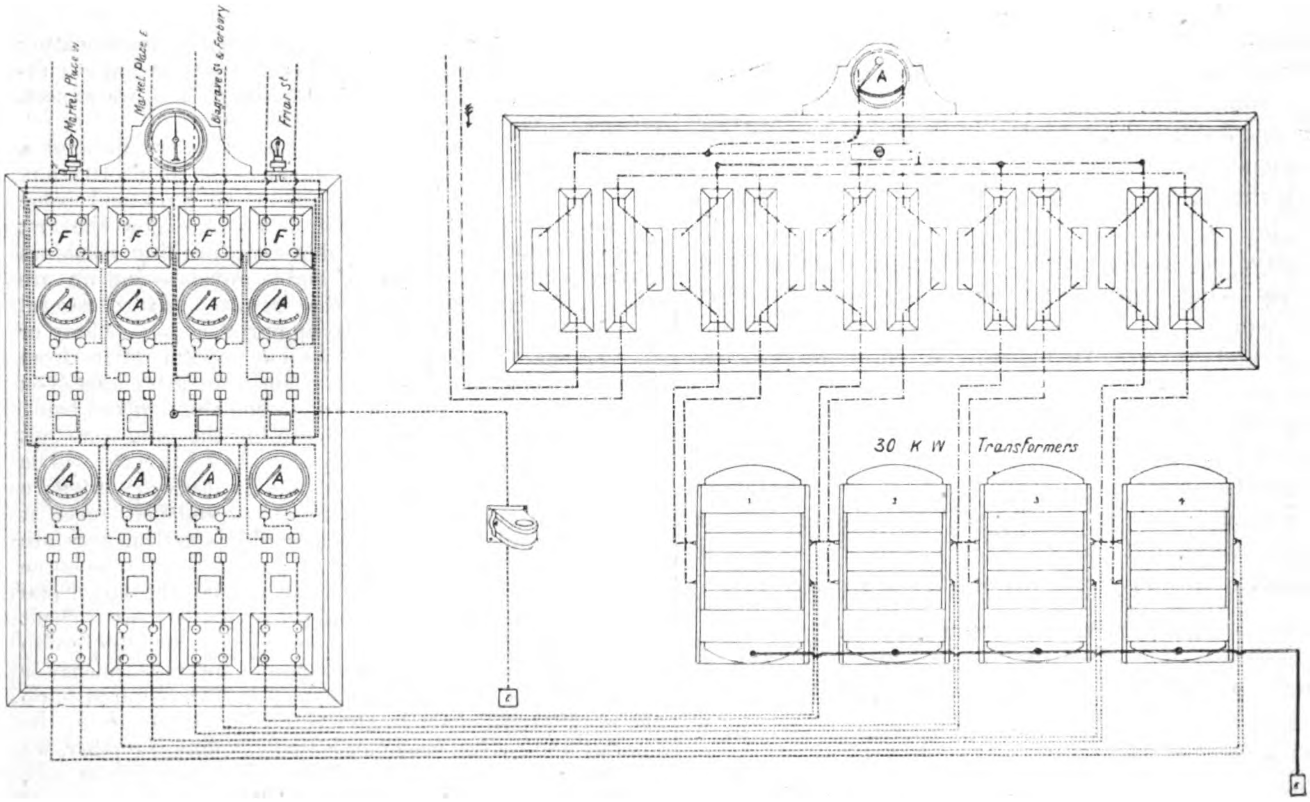

FIG. 1.—Diagrammatical Arrangement of Connections.

Fig. 1 shows diagrammatically the arrangement of connections adopted, which is similar in both stations. The high-tension connections are made with Silvertown cables, Class C, 2,500 megohms per mile, and the low-tension connections with Callender's standard vulcanised cables, 0·4 square inch area solid cored. Fig. 2 is from a photo-

into spring contacts on the board, mounted on a piece of slate, which is again mounted on a polished teak bar with ebonite handle. The blades are connected together by fine wires so that a combined switch and fuse is obtained. Slate slips standing perpendicularly to the board are placed between the poles, so that each pole of each switch is

Digitized by Google

confined in a separate compartment of slate. This is no doubt one of the safest forms of high-tension switchboard which has yet been devised.

The switches on the low-tension boards are Messrs. Paterson and Cooper's D.P. hatchet type. The amperemeters are a new design of gravity instrument, suitable for direct or alternating currents. For any frequency from 40 to 100 they are practically correct without recalibration, while when calibrated for direct currents, the error, if placed on an alternating circuit of 100 periods, does not exceed

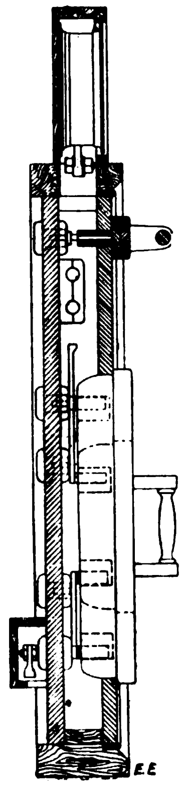

FIG. 3.—Section of High-Tension Board.

2 per cent. The double-pole fuses are protected by hinged cases with glass fronts, so that should a fuse blow when the attendant is near there is no fear of his being struck by the pieces of molten metal. Both the high and low tension boards are mounted in polished teak frames, and are placed about 18in. from the walls of the stations, doors being fitted at the ends of the boards to give access to the back connections.

The arrangements described are the joint design of Mr. F. F. Yeatman, engineer to the Reading Supply Company, and Mr. C. W. Hill, manager to Messrs. Paterson and Cooper.

AWARD OF THE EVENING EXHIBITIONS.

The examination papers for the award of the evening exhibitions in science and technology were published in the June number of the *London Technical Education Gazette.* We gathered that there were 88 of these exhibitions awarded this year. The examiners' report is most interesting, and we find that these exhibitions are of the value of £5 per annum, and are tenable for two years. They correspond generally with the evening art exhibitions, and are held under very similar conditions. The payment is made to each exhibitioner in four quarterly instalments, and is intended to cover the amount of his class fees and travelling expenses incurred in attending evening classes. Not more than 100 were offered for competition in April last, and for these 285 candidates sent in their names, of whom 47 failed to present themselves for the examination, which was conducted simultaneously at the People's Palace, Regent-street Polytechnic, the South-West London Polytechnic, Battersea Polytechnic, the Borough Polytechnic, and Woolwich Polytechnic. Of the candidates 33 submitted works of various kinds, and 50 submitted drawings generally relating to building construction, machine construction, or practical geometry. Among the works submitted there were a number of very good examples of lead bossing, and there were some other specimens of actual pieces of work, but there were too many examples of unworkmanlike work such as one expects to see exhibited by amateurs at industrial exhibitions. There were a few good examples of building construction carried out necessarily on a small scale, but useful as models for teaching purposes, but there were also examples of very serious waste of time in the construction of models of no conceivable use except as illustrating the patience and perseverance of the workers.

Of the drawings submitted there were several sheets of rough sketches apparently made in classes from lecture diagrams, and useful in their way as showing the nature of the class teaching in some of the technical institutes and classes. There were also some well-finished drawings of a practical character, but there were many serious examples of time and opportunity wasted in the mere copying of "pictures," the copyists, in some cases, obviously having no idea of the constructional details of the mechanism they were representing, while in many cases the chief feature of the work was the high and varied colouring. One candidate who entered for machine construction, but gained only 7 per cent. of the possible marks in the paper on that subject, submitted a sectional drawing in pencil of a locomotive on the North London Railway. The drawing had occupied between 200 and 300 hours, and was full of the most carefully-executed and minute details. Had it been submitted by a lithographic or wood-engraver's draughtsman it would have deserved credit for the accuracy of its technique, but as the work of an engineer's apprentice it is an example of serious waste of time. Of the drawings of engines there were two very similar in general character and both neatly finished in water-colour, but of widely different educational value. One represented a 40-h.p. horizontal engine of about 100 years ago, full of elaborate architectural decoration, carried out in cast iron, and apparently copied from some published lithograph. The other was also a drawing of a horizontal factory engine, but an engine which had been recently erected in Woolwich Arsenal and was provided with Proell trip gear, but the chief feature of the drawing was that it had been executed from dimensions taken by the candidate himself on the actual engine. There can be no comparison made between the educational value of these pieces of work.

In analysing the results of the examination for evening exhibitions in science and technology, and comparing them with the results of last year, it is interesting to note an increase in the number competing, and also in the number of exhibitions awarded. A much larger proportion of the successful candidates previously attended classes in polytechnics or other institutions aided by the Board, the proportion being 84 per cent. as against 76·6 per cent. last year, whereas the number obtaining exhibitions from continuation schools is much less, being 6·8 per cent. as against 14·3 per cent. The number submitting specimens of practical work is also much greater this year than last. The majority of the successful candidates consist of men engaged in engineering, building, carpentering, and plumbing trades. The class of students attracted by these exhibitions is exactly the class for whom they were specially designed by the Board.

Of the 88 successful candidates 73 have attended classes at polytechnics—viz., at Battersea 23, at the People's Palace 22, at Woolwich 10, at Regent-street 8, at the South-West London 4, at the Borough 2, at the Goldsmiths' Institute 2, at the Birkbeck Institution 1, and at the City of London College 1.

The following was the paper set for this examination in electricity and magnetism and electrical engineering. The candidates were not expected to answer more than eight questions:

1. What is meant by a magnetic field of unit strength? Explain fully the meaning of the statement that the magnetic induction in the armature core of a dynamo is 12,000 C.G.S. units, and point out the advantage of keeping this induction as low as possible.

2. Describe a good form of tangent galvanometer. What is the "constant" of a galvanometer, and how would you determine it?

Digitized by Google

3. Mention the principal methods available for the measurement of an electric current of a few amperes and describe fully the manner in which you would measure a current by means of a calorimeter.

4. Describe the construction of some form of ampere-meter or voltmeter suitable for an ordinary switchboard.

5. A country house is to be lighted by means of storage cells charged by a dynamo, the battery-room being in the immediate proximity of the engine-room. Make a sketch of a suitable switchboard containing all the instruments, switches, and accessories which you consider desirable for the purpose, showing all the connections, but omitting the details of the instruments.

6. What is meant by the characteristic of a dynamo? Sketch the characteristics of a pure shunt dynamo and of a series dynamo. What class of dynamo would you select for the purpose mentioned in the last question, and why?

7. A building has been wired with 20 independent circuits proceeding from a distributing double-pole fuse-board. You are required to test the circuits in order to ascertain whether they satisfy insurance regulations. What instruments would you employ, and how would you proceed?

8. A length of 110 yards of "concentric" cable has developed a fault between the two conductors. How would you proceed to ascertain the precise position of the fault, both ends of the cable being accessible in the test-room?

9. Describe some form of arc lamp suitable for alternating current. You have to arrange two 25-ampere arc lamps on an alternating circuit in which the current is supplied at 100 volts. What arrangements would you make?

10. Describe the construction, including the winding, of some good form of armature for a continuous-current dynamo.

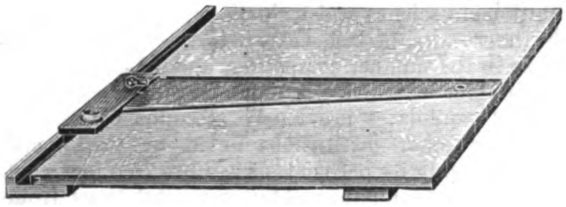
11. A current of 1,000 amperes is carried through a mile of copper conductor of one square inch sectional area. If the fall of potential be one volt for every 40 yards, how many horse-power will be wasted in heating the conductor?

What saving of power would be effected if the same energy were transmitted through the cable by means of half the current at double the pressure?

12. Describe Lord Kelvin's milliampere balance.

THE STANLEY-HOWARD COMBINED DRAWING-BOARD AND TEE-SQUARE.

We were shown this improvement recently, and think it should find favour with draughtsmen. The form of the apparatus, which is patented, is seen in the illustration. The object of the invention is to provide a tee-square which can be easily



and truly clamped to the board at any point. To enable this to be done the end frame is made of an L section, so that a groove is left at the end of the drawing-board, in which the tee-square slides. This groove is not used as a guide, but the edge of the drawing-board determines the position of the tee-square in the usual way. The head of the square has projecting through it a small bolt with a lever on its upper end and a cam at the other. When the lever is turned the cam engages on the side of the L frame, and forces the true surface of the square against the turned surface of the drawing-board. A little extra pressure on the lever then secures the square in position, so that the draughtsman can work on the extreme end of the blade without holding the square. This will be found to be of great assistance when fine work with the set square has to be done, as it permits the draughtsman to use both hands. The construction of the clamping device is such that all the pressure of the metallic part of the cam only affects the frame and not the trued surfaces. The frame also protects the adjusted edge of the board from mechanical injury. Another handy detail in the square is that of allowing the blade a slight swivel when required. So in putting back old drawing on to the board the square can be set to the drawing, instead of the old practice of adjusting the drawing to suit the square.

This adjustable square will be found of great service when working at the extreme lower edge of the board. We understand that these sets are to be obtained from Messrs. Stanley and Co., Great Turnstile, at reasonable prices.

THE CONVERSION OF THERMOMETER READINGS.

BY A. H. ALLEN.

It is frequently necessary to convert readings of temperatures which have been observed on the Centigrade scale into the corresponding values on the Fahrenheit scale, and *vice versâ*. For this purpose tables have been compiled, but these usually advance by steps of one degree, and therefore involve calculation in the case of fractional values.

To convert from °C. to °F., therefore, it is usual to multiply by $\frac{9}{5}$ and add 32, and to convert from °F. to °C. subtract 32 and multiply by $\frac{5}{9}$.

An easier method by which the operation may be performed mentally, in less time than it takes to get a sheet of paper and write down the figures, and which is perfectly accurate, is given below.

(i.) To convert °C. into °F.:

Since $\frac{9}{5} = 1{\cdot}8 = 2 - {\cdot}2$, multiply by 2, from the product subtract the same figures *moved one place to the right*, and add 32. Thus, to convert 73° C. into °F.:

	73
Multiply by 2	2
	146
Repeat figures one place to right	14·6
Subtract...	131·4
Add 32	32
	163·4

Hence 73° C. = 163°·4 F.

(ii.) To convert °F. into °C.:

$$\tfrac{5}{9} = {\cdot}55555 \;.\;.\;.\;.\;.$$
$$= {\cdot}5 + {\cdot}05 + {\cdot}005 + \;.\;.\;.\;.$$
$$= \tfrac{1}{2} + \tfrac{1}{20} + \tfrac{1}{200} + \;.\;.\;.\;.$$

Therefore, subtract 32, divide by 2, and to the quotient add the same figures twice or thrice, *moved one place to the right each time*. Thus, to convert 80° F. into °C.:

	80
Subtract 32..	32
Divide by 2..	2)48
	24
Repeat figures one place to right............	2·4
Repeat this..	·24
	26·64

Hence, 80° F. = $26{\cdot}\dot{6}$° C.

The result in this case is always a recurring decimal, from the nature of the multiplier—*i.e.*, $\cdot\dot{5}$; and therefore the process must be carried far enough to indicate the correct value of the last figure.

Both of these processes can easily be done mentally, as will be found on trial, and with far less trouble than is involved in finding the tables or working out by the ordinary method.

REFUSE DESTRUCTION AT DEWSBURY.

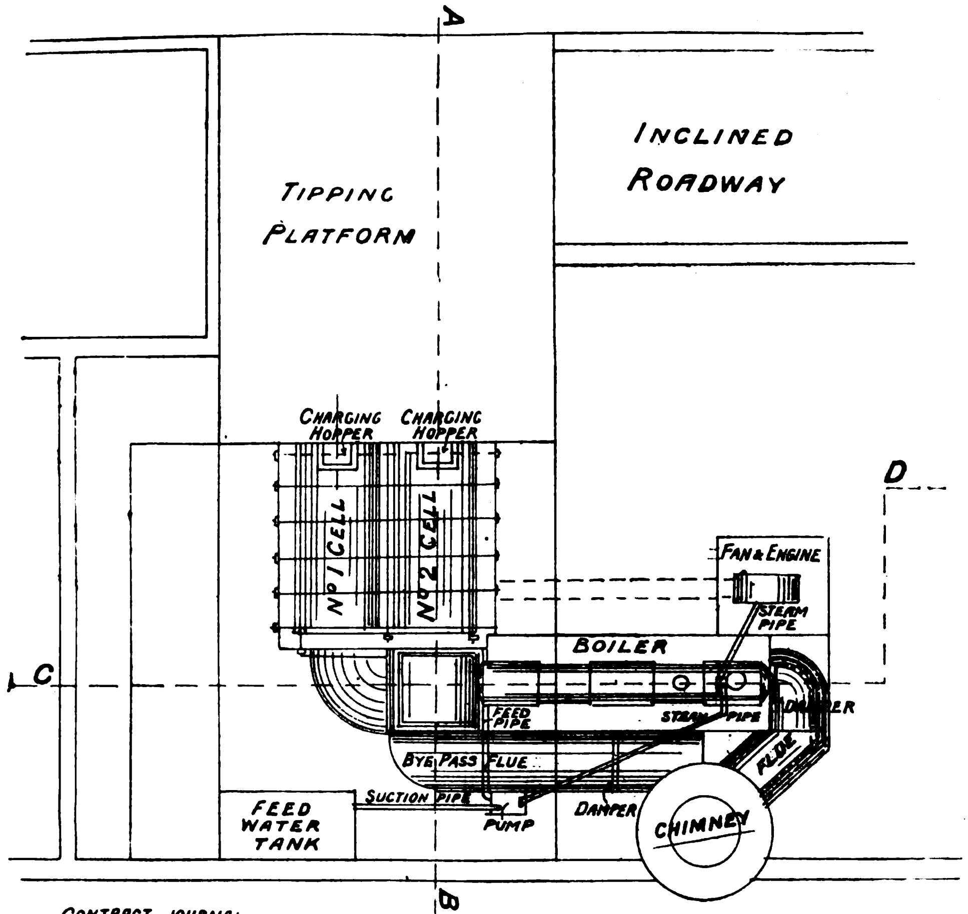
A short time ago a new refuse destructor on the Beaman and Deas system was started at Dewsbury. The illustrations we give herewith will save a lengthy description. The destructor furnaces are built in pairs, and each has an inclined hearth leading from a tipping platform 8ft. 9in. in height to a horizontal fire-grate. Beyond the grate there is a fire-bridge, and beyond this bridge a screen of perforated brickwork, the space between the bridge and the screen forming what is known as the combustion chamber, which is common to both furnaces. A reverberatory arch stretches over the combustion chamber, fire-grate, and hearth, from front to back. The ashpit is hermetically sealed and forced draught is let into it by means of a fan. In order to utilise the heat generated, a water-tube boiler of the Babcock and Wilcox type is erected behind each pair of furnaces. The fumes from the charge lying upon the hearth pass through

Digitized by Google

the fire directly over the fire-bars. The fire-bridge is hollow, and perforated at the back. The perforations communicate by a passage with the outer air, and a strong draught is created, the air in its course being heated, and giving, on its escape into the combustion chamber through the perforations of the bridge, a supply of heated oxygen, which meets any fumes passing over the bridge, and thus ensures their perfect combustion. The action is, in fact, similar to that of a Bunsen burner, so familiar to our readers.

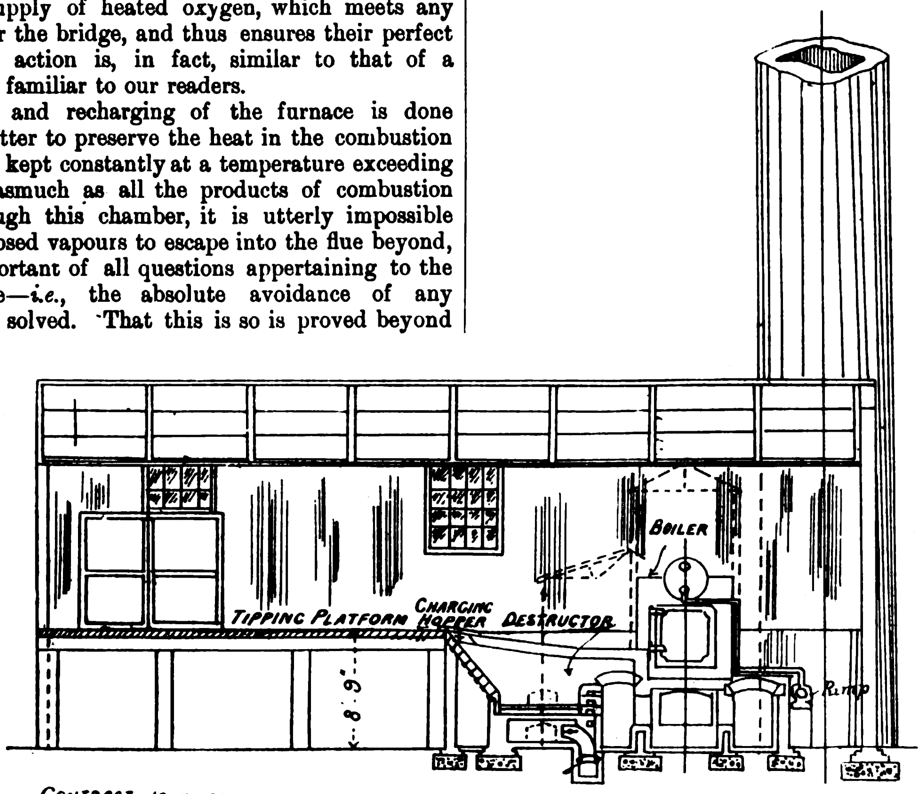
The clinkering and recharging of the furnace is done alternately, the better to preserve the heat in the combustion chamber, which is kept constantly at a temperature exceeding 2,000deg. F. Inasmuch as all the products of combustion have to pass through this chamber, it is utterly impossible for any undecomposed vapours to escape into the flue beyond, and the most important of all questions appertaining to the disposal of refuse—*i.e.*, the absolute avoidance of any nuisance—is thus solved. That this is so is proved beyond doubt by repeated analyses of the gases as they pass to the chimney shaft.

It might be expected that the great heat generated would destroy the firebrick lining of the furnaces, but this is not the case. The siliceous particles given off by the burning refuse attach themselves to the roof of the furnace and the surrounding brickwork in a stalactytic form, and thus provide a complete protection, consisting of a material which is a non-conductor of heat. Indirectly, therefore, the high temperature is the means of preserving the brickwork.



PLAN

Dewsbury Refuse Destructor.



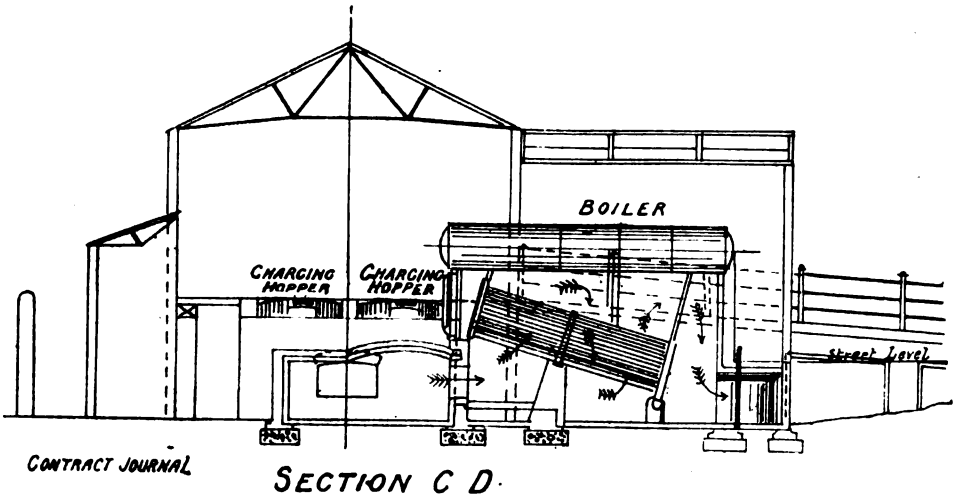
SECTION A.B.

Dewsbury Refuse Destructor.

Digitized by Google

Messrs. Bennett and Druce, electrical engineers, of Preston, have recently made a test with a two-cell destructor and a Babcock and Wilcox boiler at Warrington. The refuse used as fuel for this test contained 48 per cent. of moisture and only 30 per cent. of combustible material. Nevertheless sufficient steam was raised to develop 200 i.h.p. per hour.

This destructor has been proved capable of burning, when worked to its full capacity, 24 tons of unscreened town's refuse per cell per day of 24 hours. Where, however, the best steam results are desired it is not always advisable to force the consumption. The incombustible residuum has been found to average from 15 per cent according to the nature of the refuse, and forms a very hard clinker, which is of value for road foundations, making mortar, and other purposes. Mixed with cement, and subjected to hydraulic pressure, it forms valuable pavement flags, equal if not superior to the best Yorkshire stone.



Dewsbury Refuse Destructor.

PHYSICAL SOCIETY.

At the ordinary meeting on June 26, Captain Abney, president, in the chair,

Mr. F. Bedell read a paper on **"Admittance and Impedance."** The author discussed the application of the method of "vector diagrams" to the solution of questions connected with alternating currents. He showed how, by a consideration of the loci of the different lines on such a diagram, many problems which require for an analytical solution a long investigation may be simply and expeditiously solved.

Mr. Blakesley asked the author what was his test of resonance. Was it that the primary current and E.M.F. were exactly in the same or in opposite phase? The term resonance was an acoustical one, and he did not see why it should be applied to one particular case in the electrical problem.

Mr. Inwards asked what degree of accuracy the author had obtained.

The **Author**, in reply, said if the applied E.M.F. and the current were brought into phase by means of a condenser in the secondary, then he called that a case of resonance. The agreement between the experimental and theoretical results was generally within from 1 to 3 per cent.

Prof. S. P. Thompson read a paper on **"The Properties of a Body having a Negative Resistance."** The author, after showing the consequences which would follow according to the laws of Joule and Ohm if the existence of a body having a negative resistance were postulated, went on to show how the observations described by Messrs. Frith and Rodgers in a paper read at a recent meeting of the society only proved that that part of the resistance of an arc which is not constant is a positive resistance that varies inversely as the current. Since it varies inversely as the current, the term $\frac{dR}{dC}$ will be negative, and so will the quantity $C\frac{dC}{dR}$, which is what they had tabulated as a negative resistance. That the resistance of the arc itself should vary inversely as the current was natural, for it might be regarded as a column of vapour, the cross-section of which is proportional to the current, and therefore increasing in its conductance in direct proportion to the current. There was no need even to suppose any (distributive) adjuvant E.M.F., which would be the other alternative to the suggestion they had made.

Mr. Swinburne asked if the numbers on which Messrs. Frith and Rodgers based their arguments were obtained by taking successive readings of a voltmeter.

Prof. Ayrton said that what they maintained was that if the arc acted as if it had a back E.M.F. and a resistance, then the resistance was a negative quantity. In ordinary cases it was not known what really constituted a resistance, but it was simply said that a circuit in which electrical energy is being dissipated at a rate proportional to the square of the current has resistance. If the loss is proportional to the first power of the current, then it was said there existed a back E.M.F. Was it impossible to imagine a circuit in which a loss of electrical energy occurred proportional to the current and a return of energy to the circuit proportional to the square of the current? In a curve showing the relation between V and C, if a tangent was drawn at any point it was not the tangent of the inclination of this tangent which Messrs. Frith and Rodgers had called the resistance; it was another quantity, which they called the electrical $\frac{dV}{dC}$. In conclusion, the author seemed to have based his paper on three misconceptions—(1) that it had been claimed that a negative resistance could exist alone; (2) that the curves given by Messrs. Frith and Rodgers showed that the ordinates were inversely proportional to the current; (3) that what was measured was the geometrical $\frac{dV}{dC}$.

Mr. Frith said that in a paper by Mr. Rodgers and himself they had defined the resistance of the arc as the ratio $\frac{dV}{dC}$, where by $\frac{dV}{dC}$ they meant, not what was ordinarily understood by this expression, but the value of the ratio obtained by superposing an alternating current on a direct current arc. In order to show that in cases analogous with that of the arc, but in which the true resistance could be verified, the electrical $\frac{dV}{dC}$ obtained by superimposing an alternating current gave correct results for the resistance, some experiments had been carried out. In one case an incandescent lamp was placed in series with some 50 ampere secondary cells and a current sent through against the E.M.F. of the cells. The value obtained for the electrical $\frac{dV}{dC}$ agreed very well with the value of the resistance obtained by dividing the P.D. between the terminals of the lamp by the current. At very low frequencies for the superimposed alternating current it was evident that the electrical oscillations could travel along the steady value curve and this was clearly the meaning of the critical frequency observed with cored carbons—namely, that under the critical frequency the superimposed alternating current travelled on the steady value curve, and over that frequency along the line joining the point on the curve and the instantaneous origin. Mr. Frith exhibited a mechanical model of the arc which he has devised. This model consists of two rods of carbon dipping in two mercury cups, which are traversed by the current. The current also passes through a solenoid, which attracts an iron core attached to the carbon rods and draws them down into the mercury, thus reducing the resistance of the instrument. Hence it can be arranged so that the P.D. between the terminals decreases as the current increases. With this model it was found that for superimposed oscillating currents of such a frequency that the moving parts are not able to follow the changes in the current, the oscillations of the current and of P.D. are in phase, and the electrical $\frac{dV}{dC}$ gives the resistance of the apparatus for various currents.

Mr. Carter asked the author how on his vapour column theory he explained the difference in the behaviour of solid and cored carbons.

Mr. Enright asked why it was absurd to suppose that a negative resistance could exist. Prof. Ayrton and Mr. Frith had made in their definitions certain restrictions; it ought, however, not to be necessary to make any such restrictions.

Mr. Blakesley asked whether, since the title of the paper by Messrs. Frith and Rodgers was the "*True* Resistance of the Arc," it was to be inferred, as the results given were negative, that a negative ohmic resistance existed in the arc. Prof. Thompson's

Digitized by Google

paper appeared to him (Mr. Blakesley) to be rather a mathematical than a physical paper.

Prof. Rucker said that the discussion showed that considerable confusion existed, and that the introduction of the term negative resistance only tended to fog matters. It was entirely wrong to argue that because you have a quantity with a positive value, therefore a negative value must also be possible. As an example, take the case of mass. If you defined as a positive mass that which was attracted to the earth, and then found that cork when immersed in water was repelled from the earth, would you therefore say that cork had a negative mass? Was not "negative resistance" a term for which some equivalent could be found which would not lead to confusion?

Mr. Hovenden made some remarks on his experiments

The **Author**, in his reply said that he did not dispute the accuracy of the results obtained by Messrs. Frith and Rodgers, but it was the interpretation which they had given of their results to which he objected. Mr. Frith now made a new reservation—namely, that the results depended on the particular way in which the increment of C and the decrement of V were made. He supposed that, if the experiment was made in a particular way, a new slope was obtained which was proportional to what was called the true resistance, and hence got a new definition of the quantity $\frac{dV}{dC}$. He (the speaker) endorsed the views of Prof. Ayrton as to the interest of the model exhibited, but the question was, Is there anything in the arc which acts as a source of energy to the circuit, either as a negative resistance or as an adjuvant E.M.F.? Mr. Frith's experiments did not give any hint as to the point where the negative resistance occurred, and the absence of any such energy-giving portion of the arc was rendered probable by the fact that the arc itself was hotter than the crater. In reply to Mr. Carter, the anomalies which occur with cored carbons were so great as to prevent any argument being based on their behaviour.

The **Chairman** (Captain Abney) said that the mere fact that the quantity $\frac{dV}{dC}$ had been defined in two distinct ways showed that the definitions would have to be modified in some way.

MANCHESTER ELECTRICITY ACCOUNTS.

The following is the report of the electric light department to the City Council for the year ended March 31, 1896, together with the revenue account, the general balance-sheet, and statement of electricity generated, sold, etc.:

Your committee have pleasure in submitting to the City Council the abstract of accounts for the year ended March 31, 1896, and also in reporting the following particulars as to the year's working. The number of consumers at the close of the year was 1,148, being an increase of 407 as compared with the previous year. The number of lamps connected was—incandescent 89,294 (of 8 c p.), arc 806, as compared with 60,632 and 385 respectively. There were also 47 motors at work representing 54½ h.p., being an advance on the previous year of 30 motors, equal to 38½ h.p. The total length of mains laid was 113 miles 742 yards. The total quantity of current accounted for was 1 801,429 units, or 93·49 per cent. of the quantity produced. As will be seen from the accounts, the financial results of the year have been good. The net profit, after defraying all charges for cost of production, etc., provision for renewals, sinking fund, and interest on loans, amounts to £11,138. 10s.

Revenue Account.

The amount derived from sales of current, which works out to 4·97d. per unit accounted for, was		£37,369 4 4
The meter rents received amount to		883 8 3
Making a total income of		£38,252 12 7
The expenditure was	£14,211 5 2	
To which is added amount transferred to renewals account	3,491 14 9	
		17,702 19 11
Showing a gross profit of		£20,549 12 8
Out of this sum the following requirements had to be met:		
Interest on mortgage debt, etc	5,149 4 6	
Sinking fund	4,261 18 2	
		9,411 2 8
Leaving a surplus or net profit for the year of		£11,138 10 0

This surplus, together with the balance of £5,499. 8s. 8d. brought from last year's account, making a total of £16,637. 18s. 8d., has been appropriated as follows:

Paid to city fund in aid of rates	£6,963 14 9
Placed to contingent fund	8,521 3 11
Carried to next year's account	1,153 0 0
	£16,637 18 8

The financial position of the undertaking at March 31, 1896, is as follows:

Total capital expenditure	£251,689 12 9
Amount of capital redeemed to date by action of sinking fund	£9,186 4 0
Balance at credit of renewals account	£7,491 14 9
Balance at credit of contingent fund	8,521 3 11
Balance at credit of net revenue account	1,153 0 0
	£17,165 18 8

The following additions have been made to the plant at the works, Dickenson-street, during the year—viz: five Lancashire boilers, with mechanical stokers; six compound condensing engines (five vertical and one horizontal) of 400 i.h.p. each; six dynamos, each of 240-unit capacity. The extension to the boiler-house is finished, also the new economiser house and feed-water tank together with the two new economisers. The battery station, Hunt's Bank, is completed, and is now ready to be charged; two new transformer sub-stations have been completed, one at Ardwick-green, the other at All Saints, and the transformers have been fixed in the latter station. The extensions of mains referred to in last year's report have been completed, and the committee are now in a position to supply current to consumers in the following streets—viz., Oxford-street, Stretford-road, London-road, Downing street, Port-street, Sackville-street, Chorlton street, Minshull-street, Swan-street, Whitworth-street, Shudehill, Withy-grove, Fennel-street, and Hunt's Bank. The demand for the supply of electricity has been and continues to be so great that further extensions of mains are imperatively necessary, and it has been decided to lay them in the following streets—viz., Great Ducie street and Bury New-road, Miller-street and Great Ancoats-street, Corporation-street, Lower Mosley street, Ardwick-green, Grosvenor street, Upper Brook-street, Great Jackson street and Upper Jackson-street, and also in the district of Victoria Park which will be supplied with current at 200 volts on the three-wire system. The provisional order authorising the above extensions of mains, and also extending the area of supply to the whole city, has been sanctioned by the Board of Trade, and is now awaiting the approval of Parliament. In accordance with resolution of the City Council, application has been made to the Local Government Board for permission to borrow the further sum of £100 000 to carry out the foregoing extensions, which are expected to be partly available for the ensuing winter.

GENERAL BALANCE-SHEET.

Liabilities.	£ s. d.

LEGAL INTELLIGENCE.

ENGINEER AND COMMITTEEMAN.

On Friday last in the Queen's Bench Division the action of Medhurst *v.* Kyffin begun the previous day before Mr. Justice Kennedy and a special jury was concluded.

Sir E. Clarke, Q.C., Mr. C. W. Mathews, and Mr Hugh Fraser appeared for the plaintiff; Mr. Cock, Q.C., Mr. Eldridge, and Mr. George Blaiklock for the defendant.

The plaintiff in this case, Mr. F. H. Medhurst, electrical engineer, of 13, Victoria-street, Westminster, sued Mr. J. B. Kyffin, of Oval House, 461, Hackney-road, who is a member of the Electric Lighting Committee of the parish of Hackney, for damages for slander, the allegation being that the defendant had spoken to Mr. G. Raper, another member of the Electric Lighting Committee of the parish of Hackney, the following words: "I say, have you heard the scandals that are going about in reference to the Electric Lighting Committee? I hear that Medhurst has given Sheehan £50. . . . Yes, I understand he has given him a £50 note." The plaintiff also complained that the defendant upon subsequent occasions repeated the slander. The Mr. Sheehan referred to was the chairman of the committee which had reported in favour of plaintiff's scheme. It was pleaded in defence that the statement was made by the defendant as a member of the Electric Lighting Committee of the parish of Hackney and in pursuance of his duty as such member, and the words were spoken *bonâ fide* and without malice, and were therefore privileged.

For the plaintiff, **Sir E. Clarke** said Mr. Medhurst was engaged in 1895 by the Hackney Vestry to advise upon electric lighting. The committee visited a number of the principal towns to obtain information, and the defendant took his son with him. The son wanted to become an electrical engineer, and defendant asked the plaintiff to take him into his office. The plaintiff refused, and that seemed to be the motive for the slander. The defendant being asked for the name of his informant in the matter, on some occasions said it was Mr. Pressland, a former employé of the plaintiff's, and at other times that it was not. The Electric Lighting Committee reported in favour of the plaintiff's scheme of electric lighting, but the matter had now been postponed, and the plaintiff had suffered a serious loss.

Evidence was called to prove the plaintiff's case, and **Mr. Cock**, for the defence, urged that the occasions upon which the statements were made were privileged. The defendant was only acting in accordance with his duty, and was only anxious that the scandal should be investigated, and had merely spoken confidentially to a fellow-member of a public body. It was the duty of every public man to enquire into any charges of corruption.

Mr. Kyffin, the defendant, was called in support of this, and denied having been actuated by any ill-feeling whatever towards the plaintiff.

Mr. Justice Kennedy, in summing up, said that he should hold that the occasions upon which the statements were made were privileged, and the question for the jury was whether, therefore, there was any such malice on the part of the defendant as to take it out of the privilege. Although no special damage had been shown, a slander upon a professional man was no doubt a serious matter.

The jury found a verdict for the plaintiff, with £400 damages.

COMPANIES' MEETINGS AND REPORTS.

INDIA RUBBER AND TELEGRAPH WORKS COMPANY.

The half-yearly meeting of the shareholders of the India Rubber, Gutta Percha, and Telegraph Works Company, Limited, was held on Tuesday at Cannon-street Hotel, E.C., Mr. Matthew Gray (managing director) presiding.

In moving the payment of an interim dividend of 2½ per cent., or 5s. a share, free of income tax, the **Chairman** said the amount of business transacted during the last six months had been about 10 per cent. greater than in any previous half-year. This was a matter for congratulation, but the additional business had not been so profitable as they could have wished, because the raw material had increased in price something between 10 and 15 per cent. There was also great competition, so that it was not easy to secure great profits on orders, but taking all things into consideration there was every reason to be satisfied with the result, and they might reasonably expect that the increase of business would continue. With reference to submarine cable work, they had had a number of cables to lay at Cuba, and very little time to do it in. But they had managed to do it, and the Cuba Company were well satisfied. Since then they had had an order of considerable magnitude from the German and English Governments. The laying of this English and German cable was a somewhat difficult piece of work owing to the shallowness of the water in some parts of the line taken.

Mr. S. W. Silver seconded the resolution.

Mr. Grant asked if the Company was likely to be involved in litigation with one of the cycle-tyre companies.

The **Chairman** said that they were advised that certain of their patents had been infringed and had taken action in the matter, but the case was not likely to come on at present. In reply to a further question, he added that, so far as he knew, their opponents had not proposed a reasonable compromise.

Mr. Lamont asked if there were any truth in a rumour that the Company had lost money by speculations in rubber, and made money by speculations in tyre companies.

The **Chairman**, in reply, said the Company had not been speculating in rubber, and, therefore, had neither made nor lost money as a consequence, and the rest of the question was understood to be also answered negatively.

The resolution was put and carried, and the meeting was then made special to consider the following resolutions: "That articles of association 101, 102, and 103 be struck out and the following articles substituted: (101) At the ordinary meeting in every year the directors shall lay before the Company a profit and loss account and a balance-sheet containing a summary of the property and liabilities of the Company made up to a date not more than three months before the meeting. (102) Every such balance-sheet shall be accompanied by a report of the directors as to the state and condition of the Company and as to the amount which they recommend to be paid out of the profits by way of dividend or bonus to the members, and the amount (if any) which they propose to carry to the reserve fund, and the account, report, and balance-sheet shall be signed by a director and countersigned by the secretary. That in article of association 104, after the word 'such,' the words 'report, account, and' be inserted. That article of association 112 be struck out and the following article substituted: (112) A firm of chartered accountants may be appointed auditors, and any casual vacancy occurring in the office of auditor shall be filled up by the directors by nominating a chartered accountant or a firm of chartered accountants to be auditor or auditors until the next general meeting. That article of association 116 be struck out, and that there be added at the end of Article 114 'and to report to the Company in general meeting thereon.'" It was explained that the main alteration was at the request of the auditor, Mr. J. F. Clarke the wording of the original article being inconvenient and old-fashioned. Mr. Clarke was not present, and a very large amount of conversation followed. It was suggested that the articles to be altered as well as the proposed new ones should be printed and circulated among the shareholders, and **Mr. Cochrane** proposed and **Mr. Lamont** seconded an adjournment of a month to allow this to be done. This was not seriously opposed by the Board, but much discussion ensued as to the date, as it was considered inconvenient to hold a meeting in August or September. Ultimately the 21st inst. was fixed for the date, and the meeting was, with one dissentient, adjourned to then.

CONSOLIDATED TELEPHONE CONSTRUCTION AND MANUFACTURING COMPANY.

The directors, in their report for the year ended March 31 last, state that the accounts nominally represent one year's trading; in reality, owing to the suspension necessary in removing the works and offices, a period of about nine months only is covered. The total receipts for the year on revenue account amount to £6,614, including £3,209 received in respect of the Edison Gower-Bell Telephone Company of Europe, Limited, Belgian lawsuit, and £1,750 transferred from revenue suspense account, being dividend declared payable on July 1, 1896, by the Edison Gower-Bell Telephone Company of Europe, Limited. Deducting the usual expenses, amounting to £1,991, this will leave a balance of £4,622, against which the directors have decided to write off various items, amounting in all to £1,821, and to reserve the sum of £1,025 against loans. This will leave a net sum available of £3,023, out of which the directors propose to pay a dividend of £1. 10s. per cent., carrying a balance forward of £1,393. The competition in the manufacturing business continues very keen. The lease of the factory and offices at Farringdon-road having expired at Christmas last, the directors, after much search in the Midlands, decided upon the purchase of some works (freehold) at Coventry at an advantageous price. There is a considerable area of ground capable of being built upon in the event of extension of manufacturing business. The saving in labour, fuel, rent, and taxes promises to be favourable, and though the boom in the bicycle trade has somewhat interfered with expectations under the first item, matters are satisfactorily settling down. Offices, etc., in London, have also been obtained upon satisfactory terms, and the directors propose that the subsidiary companies shall be asked to remove to the same building as soon as convenient. The lawsuit in Belgium carried on by the Edison Gower-Bell Telephone Company of Europe has had a satisfactory termination as regards certain of the infringing companies, and a large sum of money has been paid in respect of damages. Further vigorous action has been commenced against the other infringing companies. The subsidiary company, the Anglo-Portuguese Telephone Company, continues to show satisfactory progress.

The fifteenth annual meeting was held yesterday (Thursday) at Winchester House, the Chairman of the Company (Mr. C. L. W. FitzGerald) presiding.

The **Chairman**, in moving the adoption of the report, said he could not disguise from them that this year their profit on trading had really reached its lowest limits. This was caused, he thought, by three things. First and most important of all was the decrease in the sale value, and that meant, as he had told them year by year, that their wages kept up while the sale value of the things they had to sell kept on decreasing. That was caused by the very severe competition that there was in the telephone world. Another serious cause of the decrease was the fact of their having moved the factory from London to Coventry, which put them to very great inconvenience in turning out the orders. They had been very busy for the last three months and were now, so that he hoped that if this improvement continued that they would have a better balance-sheet to show next year. Two shareholders had written suggesting that the Company ought to go into liquidation, but this question was fully discussed at the last meeting, when they decided to move to Coventry. He proposed that a dividend of 1½ per cent. should be declared.

This was seconded.

A long discussion took place on the balance-sheet, several shareholders pointing out the absurdity of a capital of £112,000 earning a profit of only £127, while the directors' fees, salaries, office expenses, and other fees and expenses amounted to over £1,800.

The **Chairman**, however, replied that they moved to Coventry because they were not doing well in London, and therefore, taking everything into consideration, they did not expect a large profit. As he had said, things had shown signs of improvement, and he hoped they would be in a much better condition at the next annual meeting.

The resolution was carried unanimously, and the other business was purely formal.

ELECTRIC POWER STORAGE COMPANY, LIMITED.

Directors: John Irving Courtenay, Esq. (chairman and managing director); Sir Daniel Cooper, Bart., G.C.M.G.; Frederick Green, Esq.; James Pender, Esq., M.P. Manager: Frank King, M.I E.E. Secretary: J. W. Barnard.

Report of the directors to be presented to the shareholders at the seventh ordinary general meeting to be held on July 16, at the offices of the Company, 4, Great Winchester-street, E.C., at 2.30 p.m.:

The net profit for the year is £4,416. 5s. 3d, which, with a balance of £170. 18s. 2d. from last year, amounts to £4,587. 3s. 5d, out of which the directors recommend the payment of a dividend of 5 per cent. on the ordinary share capital, which will absorb £4,243. 3s. 10d., leaving £343 19s. 7d. to be carried forward. Provision has been made for the maintenance of buildings plant, tools, etc., at a cost of £2,272. 16s. 8d. The quantity of the Company's manufactures sold during the past year shows a satisfactory increase. The Company has acquired, after long and exhaustive experiment, the patents for the United Kingdom and an interest in certain foreign patents covering a new storage cell, in which considerable reduction in weight and space is obtained without increase of cost. The retiring director is Sir Daniel Cooper, Bart., G.C.M.G., who offers himself for re-election. The auditors, Messrs. James Meston and Co., chartered accountants, also offer themselves for re-election.

UNITED RIVER PLATE TELEPHONE COMPANY, LIMITED.

The report of the directors of this Company for the year ending March 31 last states that the receipts and expenses have been taken at the actual sterling value each month, thus obviating the necessity for the item loss on exchange, which has appeared in the accounts in past years. The gross receipts in sterling for the year in the River Plate were £48,744, as against £36,673 for the year before, and the working expenses in the River Plate £24 967, as against £17,558, leaving a profit, after the deduction of debenture interest and all London charges, of £14,505 as against £9,902, to which has to be added £4,619 brought forward from the previous year, making a total of £19,124. Out of this sum the directors propose to transfer £3,000 to depreciation and renewal fund, and recommend that a dividend of 4 per cent. (free of income tax) be paid upon the ordinary share capital of the Company, and that the balance o £4,524 be carried forward. The capital outlay was £2,682, as against £2,662 last year. There is every prospect that the improvement in the business of the Company will continue. The shareholders' meeting is fixed for next Tuesday at Winchester House.

Crewe.—The Corporation invite schemes and tenders (*a*) for erection of a refuse furnace and boiler upon land adjoining the site of their isolation hospital; (*b*) supply and erection of an engine and dynamo, laying of electric lighting mains, and placing a complete electric lighting installation in the hospital buildings; (*c*) supply of accumulators, sufficient for the electric lighting installation. Particulars of instructions may be obtained from Mr. Fredk. Cooke, town clerk, Municipal Offices, Earle-street, Crewe, to whom sealed tenders should be sent before 10 a.m. on 14th inst.

CONTRACTS FOR ELECTRICAL SUPPLIES

CONTRACTS OPEN.

Bucharest.—Tenders will be received up to August 8 by the Roumanian Government (Department of Posts and Telegraphs) for the electric lighting of the new Posts and Telegraph building at Bucharest.

Spandau.—Tenders are wanted at the Royal Small-Arms Factory for 900 incandescent electric lamps by July 17. Particulars are obtainable for 75pfg. (9d.) from Die Königl. Direktion der Gewehrfabrik (Geschäftszimmer No. 21), Spandau.

Amsterdam.—Tenders will be received up to 21st inst. by the Engineering Department, Plantage Lijnbaansgracht, Amsterdam, for work in connection with the establishment of telegraphic and telephonic lines. The amount is slightly under £2,000.

Rheinbach (Germany).—Tenders are wanted by the Municipal Authorities of Rheinbach for various machinery for the waterworks and electric light supply, including boilers, engines, a dynamo, and storage battery. The date for tendering is 15th inst.

Simla (India).—The Municipality is inviting tenders for lighting by electric light for a term of years the principal thoroughfares and buildings belonging to the Municipality. Tenders must be submitted by September 1 next. Should any proposal be accepted, the Municipality will afford the successful tenderer all facilities to extend the system of lighting to private houses.

Cologne.—Tenders are required by the Municipal Authorities for the construction and working of electric tramways in the city of Cologne to an aggregate length of 20·3 kilometres (12½ miles). Specifications, plans, and particulars are obtainable for 10 marks (10s.) from der Registrateur B, des Oberbürgermeisteramt, Köln, Germany, and tenders must be in by November 6.

Madras.—Tenders are invited for the lighting by electricity of Government House, Madras, including the banqueting-hall and aide-de-camps' bungalow, and also for the lighting of Government House, Guindy, including the military secretary's bungalow. For particulars application must be made to the consulting architect to the Government, Chepank, Madras. Tenders will be opened on November 11, 1896.

London, W.—Tenders are required for the supply of (1) coal to the electric lighting station, South Ealing; and (2) coal and coke to the other depôt of the Urban District Council. Printed forms of tender, conditions of contract, etc,, and any further particulars can be obtained on application to Mr. C. Jones, C.E., surveyor to the Council, between 10 and 4. Tenders, in envelopes provided, to be delivered by 4 p.m. on 16th inst.

Lisbon.—The Royal Portuguese Railway Company want tenders by July 22 for the supply of 10,000 porcelain insulators with galvanised iron supports, 200 sheets of asbestos (1 metre square by 2 millimetres thick), and about 2½ tons of galvanised iron wire. The tenders are to be addressed to the Chief of the Stores Department at Santa Apolonia Station, Lisbon and particulars can also be obtained at Paris, Rue de Châteaudun 28.

Voghera (Italy).—In view of the expiration of their contract with the local gas company in 1898, the municipal authorities of Voghera are desirous of receiving during the present year propositions for the lighting of the town either by the electric light or a mixed system of gas and electricity. The population is 16,000. Application should be made to L'Administrazione Comunale, Voghera, who will give all particulars necessary.

Battersea (London).—The St. Mary's Vestry will receive tenders up to July 14 for a complete installation of the electric light for the town hall and municipal buildings. Specifications and conditions can be obtained from Mr. R. Hammond, Ormond House, Great Trinity-lane, E C., after a deposit of two guineas has been made with the Vestry Clerk, at the Vestry Offices, Lavender-hill, S.W. Clauses for the payment of trades union wages will be embodied in the contract.

Mexico.—The municipal authorities of the city of Mexico are prepared to receive proposals for the street lighting by incandescent lamps for a period of eight years. Tenders should be sent in by August 31. The Secretary of State for Foreign Affairs has received from the British Consul at Mexico a pamphlet issued by the Municipal Council of the city containing particulars as to the tenders, and this may be seen on application to the Commercial Department of the Foreign Office between the hours of 11 and 6.

London.—The Vestry of St. Pancras invite tenders for the supply of Welsh and other steam coal for use at the Regent's Park and the King's-road central stations for 12 months from August 1. Delivery to be made as required; average about 100 tons per week. Copies of the specification, conditions of contract, and form of tender to be obtained upon application at the electricity department offices, 57, Pratt-street, N.W., on payment of a deposit of 5s. Tenders to be sent to Mr. C. H. F. Barrett, vestry clerk, Vestry Hall, Pancras-road, endorsed "Tender for Coal," by 12 noon on 16th inst.

Bedford.—Tenders are invited by the Urban Sanitary Authority for supply of steam coal to the electricity works, for one year ending July 23, 1897. The coal to be one of the following kinds: Annesley hard coal, Pilsley ditto, Linby ditto, or from some other approved colliery. Sealed tenders, endorsed "Tenders for Coal," to be sent to Mr. T. S. Porter, clerk, Town Hall, Bedford, by 14th inst., with samples of the coal proposed to be supplied. Every tender must be in a printed form, a copy of which may be obtained at the clerk's office. The person whose tender is accepted will be required to furnish the colliery certificate.

San Juan (Puerto Rico).—H.M. Secretary of State for Foreign Affairs has received from H.M. ambassador at Madrid a copy of a Spanish Royal Order which has appeared in the *Gazette* inviting tenders for the construction and working of a telephone system in San Juan de Puerto Rico. A deposit of 800dol. must accompany each tender. which will be considered on August 10. The copy of the Royal Order may be seen on application to the Commercial Department of the Foreign Office between the hours of 11 and 6.

Hull.—Tenders are required by the Electric Lighting Committee for the supply of best South Yorkshire hard steam doubled-screened nuts for 12 months ending June 31, 1897, in accordance with the conditions set forth in the form of tender, which may be obtained at the Electric Lighting Offices, Dagger-lane. The contractor will have to enter into the usual form of contract required by the Corporation. Tenders, endorsed "Double-Screened Nuts for Electric Lighting Station," to be sent, under seal, to the chairman of the Electric Lighting Committee, Town Hall, by noon on 30th inst. Mr A. S. Barnard, borough electrical engineer, Electric Lighting Station, Dagger-lane.

Edinburgh. Tenders are invited for the works in proposed additions and alterations to the central electric lighting station at Torphichen street, consisting of foundations and settings for engines, boilers, etc, new upper flat over boiler-house, and other relative works, for the Magistrates and Council. Plans, specifications, and general conditions of contract may be seen at the office of the Burgh Engineer, 1, Parliament-square, from whom schedules of quantities and forms of tender may be obtained on deposit of £1. 1s., which will be returned on receipt of a bona fide tender. Sealed tenders, endorsed "Tender. "Additions and Alterations, Central Electric Lighting Station Edinburgh," to be lodged with the burgh engineer by 10 a.m. on 13th inst.

Wallasey.—For condensing apparatus and steam and exhaust pipes in connection with their electric light installation, tenders are invited by the Wallasey Urban District Council. Drawings may be seen, and copy of the specification obtained, on application to the engineer, Mr. J. H. Crowther, at the Gas and Waterworks, Great Float, near Birkenhead, on payment of £2. 2s., to be returned on receipt of a bona fide tender. Sealed tenders, on the form provided, addressed to the chairman of the Gas and Water Committee, and endorsed "Tender for Condensing Apparatus, etc.," to be delivered at the office of Mr. W. Danger, clerk to the Council, Public Offices, Egremont, Cheshire, by 4 p.m. on July 16 The contractor will be required to enter into a bond, with approved sureties, for the due performance of the contract.

Army Contracts.—The Secretary of State for War gives notice that tenders for specific quantities of the following articles will probably be invited from time to time during the next twelve months — namely: submarine mining electrical instruments, telegraph cable and wire, etc. Manufacturers who may wish to be applied to when tenders are required should address the Director of Army Contracts, War Office, Pall-mall, S.W., by letter, stating the particular articles which they manufacture, and the names of at least two well-known firms or public bodies who have purchased from them, and are in a position to certify as to the quality of their productions. Applications unaccompanied by references will not be noticed. Firms whose names are already on the War Office list need not apply, as forms for tendering will be sent to them in due course.

Egremont (Cheshire).—Tenders are invited by the Wallasey Urban District Council for the erection of an additional six-celled Fryer's patent refuse destructor, with Boulnois and Brodie's patent charging apparatus, Jones's fume cremator, steam-engine, and mortar mills, together with additional roofing buildings and electric lighting in connection with the existing refuse destructor works at Gorsey-lane, Poulton. Plans may be seen and specifications and forms of tender obtained on payment of £2. 2s, which will be returned on receipt of a bona fide tender, at the offices of the engineer and surveyor, Mr. Arthur Salmon, A.M.I.C.E. Separate sealed tenders, addressed to the chairman of the Health Committee, and endorsed "Destructor Contract D, E, F, or G," as the case may be, to be left at the office of Mr. W. Danger, clerk, Public Offices, Egremont, by 5 p m. on 20th inst. The contractor will be required to enter into a bond, with approved sureties, for the performance of contract, which contract and bond will be prepared at the expense of the contractor.

Kingston (Jamaica).—The Colonial Government invite electric tramway contractors willing to undertake the establishment and working of a system of rapid transit to send in applications for the grant of a license by the Governor in Privy Council under the Tramways Law, 1895. In all applications the principal questions to which attention should be directed are the following: (*a*) the amount of capital which the applicants are prepared to subscribe; (*b*) the system which it is proposed to establish; (*c*) the mileage of lines to be laid; (*d*) the fares to be charged; (*e*) the frequency of the service; (*f*) the length of the license required by applicants; (*g*) the guarantee which the applicants offer for the satisfactory performance on their part of any obligations devolving on them. Plans of the city of Kingston and part of the parish of St. Andrew, showing the routes on which the present tramway lines are laid, and copies of the law under which licenses are granted and of the rules made thereunder by the Governor in Privy Council, may be seen at the office of the Crown Agents for the Colonies, Downing-street, London, S.W. All applications must be delivered not later than July 31, 1896, in a sealed packet, marked on the outside "Application for Tramway License," to the clerk of the Privy Council, Kingston, Jamaica. Kingston has its principal means of transit at present supplied by the Jamaica Street Car Company by horse tramcars, the entire length of lines laid being about

Digitized by Google

12 miles. The concession granted by the Legislature of the island to the Jamaica Street Car Company will shortly expire.

RESULTS OF TENDERS.

Bristol.—The Docks Committee have accepted the tender of Messrs. King, Mendham, and Co., of Bristol, for the electric lighting of the chill-rooms at the foreign animals wharf, Cumberland Basin.

Wakefield.—The West Riding County Council have accepted Messrs. Harding and Turton's tender for wiring in connection with the electric lighting of the county hall. The amount was £1,527. 10s.

Paisley.—The Corporation have accepted the tender of the Brush Electrical Engineering Company, Limited, to wire the George A. Clark Town Hall for the sum of £844, and also to supply an engine for the installation at a cost of £565.

Brussels. - For the materials and work in connection with the installation of the electric light at the Malines locomotive works the successful tenderers were the Compagnie internationale de l'electricité, Liège, at 7,403fr. There were nine tenders. No English firm tendered.

Rochdale.—For the electric lighting plant required at the free public library, consisting of gas-engine, dynamo, wiring, and fittings, for the Free Library Committee (Mr. S. S. Platt, A.M.I.C.E., borough surveyor), the tender of Messrs. Fletcher, Hirst, and Co , Burnley, was accepted.

Paris.—At the Postal and Telegraphic Department of the French Government, on June 25, contracts were awarded for 125 metric tons of galvanised-iron wire (three millimetres) to the Société de Commentry-Fourchambault, at 229·40fr.; and for 3,000 iron cross-pieces, with accessories, to the Forges de Franche Comté, Besançon, at 11,640fr. The contract for a million screws was not awarded, the lowest tender being 28,750fr., nor were the two other contracts for accessories.

London, N.W.—The following tenders were received by the Vestry of St. John, Hampstead, for the extension of the electric lighting station in the parish stoneyard, Lithos-road, Finchley-road, N.W. :

A. J. Chessum and Sons, Crown Works, Haggerston (accepted)	£7,499
J. Simpson and Son, 48, Paddington-street W.	7,551
Scharien and Co., Trafalgar square, Chelsea	7,583
R A. Yerbury and Sons, Birchington-road, Kilburn	7,600
R. Ballard, Limited, Child's Hill, N.W.	8 995

Leeds.—The City Council received the following tenders for an electrical installation sufficient for the working, by the overhead system of haulage, a double track of tramway seven miles long :

J. Russell and Sons, poles and brackets	£3,607	0	0
Greenwood and Batley, underground conduits and conductors	4,553	1	3
Crompton and Co., trolley wires and attachments (withdrawn)	3 370	0	0
Greenwood and Batley, electric motorcars	14,000	0	0
Chloride Electrical Storage Syndicate, accumulators and switches	1,341	0	0
Greenwood and Batley, steam-engines	3,507	0	0
Greenwood and Batley, dynamos, etc.	3,200	0	0
Clayton, Son, and Co., boilers, etc.	1,371	0	0
J. T. Wright, generating station	5,815	0	0

BUSINESS NOTES.

Direct Spanish Telegraph Company.—For the month of June the receipts were £1,960.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,855.

Boston (Lincs.).—The Town Council are considering the advisability of erecting an electric light installation for the town and the dock.

Rangoon (India).—The new Government House is lighted by electricity. The Jubilee Hall is also to be lighted by the same means.

Globe Telegraph and Trust Company.—The directors recommend a dividend of 3s. 9d. per share, leaving about £1 000 to be carried forward.

Peterborough.—The Local Government Board have refused to sanction the loan by the Town Council of £20,000 for electric lighting purposes.

Birkenhead.—It was stated at the last meeting of the Town Council that the electric light would be ready for consumers, it was hoped, in August.

Derry.—The Lighting Committee of the Corporation have decided to shift the electric lamps in the Diamond nearer to the School of Art, at a cost of £7. 10s.

Richmond (Yorks).—It is stated that the Castle Mill is to be used for electric lighting The question is before a select committee for consideration.

Wrexham.—The Town Council have decided to apply to the Board of Trade for a provisional order for the purpose of supplying electric light for the borough.

West India and Panama Telegraph Company.—For the two weeks ended June 30 the receipts were £2,382, as against £1,863 for the corresponding period of 1895.

Great Northern Telegraph Company.—For the month of April the receipts were £25,600

Oldham.—The Town Council have decided to make application to borrow a further sum of £10,000 in connection with the proposed extension of the electric lighting scheme.

British Incandescent Electric Lamp Company, Limited.—This Company has been formed, with a capital of £10,000, to carry on business as electrical engineers and electricians.

City and South London Railway.—The returns for the week ended July 5 were £881, compared with £915 for the corresponding period of last year, being a decrease of £34.

Belfast.—A largely-attended meeting of Belfast telegraphists, presided over by Mr. T. J. Wilson, has been held at the Artisans' Hall. The object of the meeting was with regard to their rate of wage.

Antimony-Gold and Complex Ores Extraction Company.—This Company has been formed, with a capital of £350,000 in £1 shares, and the present issue is 50,000, at premium of 10s. per share.

Hull.—The proposal of the Finance Committee to spend £40,000 on an additional electric lighting undertaking will, it is understood, come up as first business at the next meeting of the Town Council.

Helensburgh—At a meeting of the Police Commission it was agreed, on the recommendation of the special committee, to abandon the scheme for lighting the burgh by electricity, as the cost was too great.

Chamounix.—The Municipal Council have just voted a sum of 100,000f. with the object of introducing the electric light. It is expected that this part of Mont Blanc will receive the new illuminant next summer.

Brighton.—The Brighton and Rottingdean Electric Tramroad Act has received the Royal assent. Clifton Cricket Club and the Electric Cricket Club met in Preston Park last Saturday, and the former won by 87 runs.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending July 5 amounted to £1,286, as compared with £1,250 in the corresponding week of the previous year, being an increase of £36.

Electricity in Mining.—The British Arsenic Mines, Limited, the Anglo-Mexican Colonisation and Trading Company, Limited, and the Barrow Salt Company, Limited, take power to construct electric works and to supply electricity.

Stafford.—At the meeting of the Town Council the Gas and Electricity Committee recommended that the electric cables should be extended along Martin-street to Eastgate-street, at a cost not exceeding £35. The report was adopted.

Bristol Tramways and Carriage Company, Limited.—The traffic returns for the week ending July 4 were £2,403. 6s., compared with £1,912. 8s. 1d. for the corresponding period of last year, being an increase of £490. 17s. 11d.

Earl's Court.—The latest addition to this resort of interest is a two-storeyed tower, which has a large electric reflecting lamp on the summit which will throw a 4,000,000-c.p. light, and will be visible at almost any point in the 12 mile radius.

Preston Electric Company, Limited.—This Company has been formed, with a capital of £3,000, to acquire the business of electrical and mechanical engineers, etc , as now carried on by G. W. Preston, and to develop and extend the same.

South Manchester Electric Supply Company, Limited.—This Company has been registered, with a capital of £5,000 in £1 shares, to carry on at Withington and elsewhere in the neighbourhood of Manchester the business of an electric supply company.

Lewisham.—The Blackheath and Greenwich District Electric Light Company have given notice of their intention to apply to the Board of Trade for a provisional order authorising the company to supply electricity for public or private purposes in the parish of Lewisham.

Simla. - *Indian Engineering* says that the electric light in this place has proved successful Still, it is doubtful whether it will be introduced throughout Simla. It will be an expensive undertaking, and people look apprehensively on changes that may increase the taxation.

Standard Dynamo and Motor Manufacturing Company, Limited.—This Company has been started, with a capital of £2 000, to acquire the business of electrical engineers, etc., as now and hitherto carried on by Thomas Preece and Co., at Bradford, Yorkshire, and to develop and extend the same.

Liverpool.—Liverpool has entered upon the experiment, which it has had in view for some years, of taking over its electric supply from the company which heretofore has had the franchise and privileges. The price the city pays is £400,000, and, according to Sir Frederick Bramwell, no better installation is to be found in the kingdom.

W. T. Henley's Telegraph Works.—The directors of W. T. Henley's Telegraph Works Company, Limited, have declared an interim dividend on the ordinary shares for the half-year ending June 30, at the rate of 6 per cent. per annum, free of income tax, and upon the preference shares at the rate of 7 per cent. per annum, less income tax, both payable on September 1.

New German Cable Company.—A new company has been formed at Cologne under the title of the "Deutsche Seetelegraphen-Gesellschaft" (the German Submarine Cable Company). The primary object of the Company is to lay a cable between Germany and Spain, and eventually to extend it to the United

Digitized by Google

States. The present share capital amounts to 3,560,000 marks (£178,000).

East Grinstead Electric Lighting Company, Limited.—This Company has been registered, with a capital of £15,000, to carry on the business of an electric light company in the parishes of East Grinstead, Forest Row, and North Sussex, and in the parish of Longfield, Surrey. Registered office: Place Land Offices, London road, East Grinstead.

Edinburgh.—The National Telephone Company have removed their South Side exchange to 1A, Hill-place to obtain superior accommodation. A new switchboard has been introduced on the multiple system, which is fitted for 600 subscribers. A new testboard has also been introduced, and in a third room is erected a series of translaters, by which a message is carried from the local to the trunk wires.

Wimbledon.—At the meeting of the Urban District Council the Road Committee reported that they had received notice from the County of London Brush Electric Lighting Company, Limited, of their intention to apply for a provisional order as to lighting Wimbledon by electricity. The Clerk stated that the company would not be able to apply for powers until July in next year, and the Council could apply at the same time.

Chelmsford.—Messrs. Crompton and Co. Limited, have just completed the arrangements for their new premises on a very convenient site, nine acres in extent, about half a mile from the old works. Large contracts for the necessary ironwork and the erection of the buildings were let immediately on obtaining possession of the land, and the Great Eastern Railway at once commenced work on the necessary sidings.

Morley.—The town clerk reported at the meeting of the Town Council that June 24 was the last day for depositing objections to the Corporation's application for the granting of a license for carrying out an electric lighting scheme, but that no objections had been deposited. Compliance with the Electric Lighting Act and the proving of plans was completed, so that everything was now ready for the scheme being proceeded with.

Cheltenham.—At a meeting of the Town Council the scheme for an electric tramway to Cleeve-hill, some three miles out of the town, was explained by the chairman of the Streets Committee. Alderman Norman moved that the matter be referred back to the committee, the suggested route being unsuitable, in his opinion. This was agreed to. The discussion showed the promoters that the Corporation viewed the proposal with favour.

Calcutta.—Messrs. Kilburn and Co., of Calcutta, have applied to the local Government for permission, under the Electric Lighting Act of 1895, to supply electric light and power to Calcutta. It is understood that Messrs. Kilburn and Co. have come to an arrangement with the Calcutta Tramways Company to supply the motive power to work their cars with electricity. The system adopted will be the low-tension continuous-current system.

Warrington.—Notice having been received from the County of London and Brush Provincial Electric Lighting Company, Limited, of their intention to apply to the Board of Trade for a provisional order to supply electrical energy for public or private purposes within the area of the borough, the General Purposes Committee of the Town Council have resolved that the town clerk give notice to the Board of Trade objecting to such notice and to the issue of a provisional order.

Dublin.—At a meeting of the Judicial Committee of the Privy Council an application was heard on behalf of the Belfast Street Tramways Company for an Order in Council authorising the construction and maintenance by the Belfast Street Tramways Company of certain additional lines outside the city boundary, and for the purpose of doubling their existing lines on the Falls-road, Ormeau-road, Shore-road, and Lisburn-road. The order was sanctioned, subject to some alterations.

Aberdeen.—The county of Fife wishes Aberdeen to co-operate with them in endeavouring to get arrangements made for the use of the telephone system on such terms that the annual cost would place that system within the reach of all the counties. The County Council have decided to remit the communication to their delegates appointed to attend the meetings of the County Councils Association, with power to them to take such steps as they might think best in the interests of the county.

Merthyr.—The Bill confirming a provisional order granted by the Board of Trade to J. C. Howell, Limited, for the production and supply of electricity in respect of the urban district of Merthyr Tydfil has been before the examiner of the House of Lords for proof of compliance with the Standing Orders. The examiner found that there had been a non-compliance in respect of the lateness of certain notices, and the matter will come before the Standing Orders Committee in due course.

St. James's and Pall Mall Company.—The directors of the St. James's and Pall Mall Electric Light Company, Limited, have declared the following interim dividends for the half-year ending June 30: at the rate of 7 per cent. per annum on the preference shares, and at the rate of 5 per cent. per annum on the ordinary shares. The sale of electricity for the quarter ending June 24, representing the supply at 6d. per unit, amounted to £10,657 as against £8,598 at the same rate for the corresponding period of 1895.

Bilbao.—In Consul Smith's report on the trade of Bilbao, after remarking on the openings for business in electrical machinery and work in Spain, that official says: "If electrical plant manufacturers write and ask me for lists of firms to which they may send their price-lists, which are made out in English, I shall reply that a list of firms will be found in the *Libro de Bilbao*, published by Lavranga y Lejarcegui, calle de Ledesma 22, Bilbao." A shorter way of putting it would be to say, "Look in the directory." Consul Smith further recommends the sending out of travellers.

Bury.—At the meeting of the Town Council, a long report was read from the surveyor as to the tramways. It was stated that a sub-committee had come to the conclusion that there could be no objection to the overhead tramway system as in use at Bristol, and as proposed by the Bury and Rochdale Tramway Company; but that, in face of the expenditure in altering the mode of traction, obtaining special powers, etc., the sub-committee considered the present an inopportune time to discuss the terms for acquiring the tramways and leasing the company power to work them.

Salford.—At the meeting of the Town Council, Councillor Thompson asked the chairman of the Gas Committee if he could not see his way to propose the lighting of the public streets with the electric light instead of gas. In this way the shopkeepers would have an opportunity of getting the electric light cheaper than at present. Councillor Holland said he could not see his way to promise anything of the sort. If the shopkeepers would purchase the cheap electric light it would enable the committee to make further extensions, but he thought it was wiser to earn the working expenses first.

Wandsworth.—On Saturday last the men employed by the Brush Company on their Wandsworth contract had an excursion to Bognor. They left London Bridge by the 8 o'clock train. Dinner was served at the Beach Hotel, Mr. G. A. Cowles presiding in the unavoidable absence of Mr. P. J. Pringle, resident engineer, and several other members of the staff were present. At the conclusion of dinner a vote of thanks was heartily accorded the Brush Company and others for their donations. During the afternoon a large party went for a drive to Chichester and back, and a most enjoyable day was spent.

Metropolitan Asylums Board.—At the meeting of this Board the North-Western Hospital Committee reported that they had had under consideration the question of lighting by electricity the new building about to be erected for the staff, and had consulted Prof. Ayrton (the electrical engineer who superintended the installation of the electric light in the new administrative block, pavilions, etc.) upon the subject. Prof. Ayrton had agreed to prepare a specification and to supervise the carrying out of the work at fees of 10 and 35 guineas respectively. They therefore recommended that Prof. Ayrton be employed on these terms, and this was agreed to.

Fulham.—The Electric Lighting and Dust Destructor Committee of the Vestry have considered the report of Mr. F. H. Medhurst on refuse destructors and electric lighting, and recommend that a deputation be appointed consisting of the chairman, vice-chairman, and four members of the committee, with Mr. Medhurst (the electrical engineer), the medical officer of health, and the surveyor, to visit the towns of Leeds, Warrington, Oldham, Brighton, Bedford, and Portsmouth for the purpose of seeing the destructors in operation and inspecting the electricity supply works. In the meantime the surveyor is to make applications for particulars of the works in progress at the towns proposed to be visited.

Birmingham.—The City Council have decided by 33 votes to 23 to accept the offer of Messrs. Mackenzie and Ross, of Montreal, to take a lease for 21 years of the system of tramways at present worked by the Central Tramway Company, whose rights the syndicate have provisionally agreed to acquire. They are to pay an annual rent to the Corporation of £5 000, to substitute an improved form of traction, probably electrical, in place of the present steam traction, to concede ½d. fares, and to shorten the hours of the tramway employés. The leases of the present company expire in 11 years and the opponents of the syndicate advocate that at the end of that time the tramways should be taken over by the Corporation.

Paisley.—At a meeting of the Town Council it was reported by the Electric Lighting Committee that they had agreed to accept the offer of the Brush Electrical Engineering Company, Limited, to wire the George A. Clark Town Hall for the sum of £844. The work is to be done to the satisfaction of Dr. Bottomley or such other consulting electrical engineer as may during the period allowed for the completion of the work be appointed by the Town Council to superintend the same, as also to the satisfaction of any resident engineer who may be appointed by the Council. It was also reported that at a further meeting the committee had agreed to accept the tender of the Brush Company to supply an engine for the installation at a cost of £565.

Telephone Directory.—In consequence of the National Telephone Company's trunk wires having been transferred to the Government and the large development of the exchange system which is anticipated, the directors of the company have issued a telephone directory which contains the names, numbers, professions or trades, and addresses of all the company's subscribers throughout the United Kingdom. The directory is arranged in a most convenient form, and will be of very great convenience to all users of telephones. A complete index to towns is given, and also to all public call offices, and for the purpose of expediting messages in London the name of the exchange is given in addition to the subscriber's number. Specially-prepared cases for binding and hanging up can be obtained.

Appointments Vacant.—A chief electrical engineer is required for the English electricity works in Madrid. He must have had the management of similar works (alternating-current system), and be able to show first-class record. Commencing salary £500 per annum, with bonus on net profits, guaranteed to be not less than

Digitized by Google

£130. Apply, in confidence, to the consulting engineer of the company, Mr. Robert Hammond, Ormond House, Great Trinity-lane, London, E.C., on or before 11th inst.—The Town Council of Salford require a mathematical lecturer, who must be qualified to assist in the physical and electrical engineering departments Salary £180 per annum. They also require an assistant lecturer and demonstrator in chemistry. Salary £70 per annum. Particulars of duties and forms of application may be obtained up to the 11th inst. from the secretary at the Royal Technical Institute.

The Metropolitan Electric Supply Company.—The directors have, in consequence of the large subscription, decided to receive no more applications for new shares except from existing shareholders of the Company. An issue was announced of 12,500 ordinary shares of £10 each at the price of £12 per share. The proceeds arising from the present issue will be expended on extensions of mains, on additions to machinery and plant, and on the formation of transformer sub-stations, whereby, it is stated, a considerable economy in working costs will be obtained. Further issues of the present capital will be made from time to time to keep pace with the development of the Company's business. It is stated that the gross revenue for the first quarter of the present year shows an increase of upwards of 23 per cent. over that for the corresponding quarter of 1895. The list closes at or before 4 p.m. to-day (Friday).

Wakefield.—The General Purposes Committee of the West Riding County Council have had under consideration the question of the electric light for the new county offices, and have had a special report prepared by Mr. Sidney à Court, London, upon the subject. The Wakefield Corporation will shortly be in a position to supply the electric light, but Mr. à Court is of opinion that very considerable economy, besides other advantages, would be secured by the County Council itself supplying electricity, and the committee will recommend the Council to lay down plant for generating electricity by steam, in combination with the heating system. The estimates are as follows: provision of plant for generating electricity by steam, in combination with the heating system, at an estimated cost of £995 for plant and £850 for storage battery; the wiring of the place in insulated iron tubes £1,450, instead of in wood casing for £800, as already provided in the estimates; and the providing of inter-telephonic communication, £270 The Council have adopted Mr. à Court's recommendations.

Torquay.—A public meeting of the burgesses has been held, convened by the mayor (Mr. Alderman Bovey) in response to a requisition signed by a number of the ratepayers and property owners of the borough, in view of the Local Government Board enquiry to be held to-day (Friday) consequent upon the application of the Town Council for sanction to borrow £22,300 for an installation of the electric light in the town. It was decided that in view of the existing indebtedness of the borough and of the inevitable further heavy expenditure the proposed installation of the electric light by the Town Council is premature, and should be deferred for the present. It was also resolved that an influential deputation be appointed to lay the above resolution before the Town Council, and also to bring it to the notice of the Local Government Board inspector at the enquiry. The resolution of the burgesses' meeting was brought before the Town Council, but it was decided not to discuss the matter, and the resolution was referred to the Electric Lighting Committee. The Ilford Electric Lighting Company have given notice of their intention to apply to Parliament for a provisional order for lighting the town with electricity.

River Plate Electric Light and Traction Company.—The River Plate Trust, Loan, and Agency Company are authorised by the River Plate Electric Light and Traction Company, Limited, to receive subscriptions for an issue by the latter company, at the price of 97½, of £125,000 5 per cent. debenture stock (part of an amount of £150,000 like stock authorised), redeemable by the company at six months' notice at 107½ interest being payable half-yearly. The prospectus points out that the stock will form a first charge on the whole of the Company's assets, the River Plate Trust and Agency being trustees for the debenture holders. It is stated that the Company's electric lighting stations are already in operation in the cities of the La Plata and Rosario and a station is in course of construction at Tucuman city. The additional capital is for the purpose of erecting a station in Buenos Ayres, the requisite authorisation having been obtained. The Company's authorised share capital is £300,000, in equal proportions of 6 per cent preference and ordinary £5 shares It is stated that the Company's revenues have increased, and it is estimated that the net results of the four stations will not fall short of £24,000. The list closes to-day (Friday)

Crewe.—At the meeting of the Town Council the sub-committee appointed to arrange details concerning the isolation hospital presented the following report, which was confirmed by the Council: "The sub-committee have had under consideration a proposal to place upon the hospital site, adjoining the laundry block, a boiler and furnaces of sufficient dimensions to supply steam for the laundry and the disinfector, and to drive an engine and dynamo for electric lighting purposes, the furnaces to be of a type constructed to burn unscreened ashpit refuse, of which 10 tons daily are available within half a mile of the site. Definite tenders for such a boiler and furnaces have been before the committee, and information has been obtained as to the cost of electric lighting plant, from which it appears that the cost of the boiler and furnaces would be £400, and the electric lighting plant and installation £418, making a total of £818. The power available for the furnaces would be sufficient to supply electric lighting to a small area surrounding the site, which there seems at present some difficulty in lighting with gas. The committee are satisfied from enquiries made, and from actual inspection of the plant elsewhere, that the proposals made can be carried out without entailing any nuisance or discomfort upon the occupants of the buildings adjoining."

Glasgow.—The report of the Tramway Sub-Committee contains the following estimate by Mr. Clark of the cost of the test route between Kelvinside and Dennistoun: "The route from Kelvinside to Dennistoun measures 4½ miles of double track. The power-house, generating plant, feeders, and motorcars would be practically the same whether the conversion were to an overhead or conduit system. In either case I estimate the cost of these, based upon a two minutes' service, would approximately be: power-house, exclusive of ground, £6,000; generating plant, £16,250; feeders for 4½ miles double track, at £1,668 per mile, £7,089; 45 new motorcars, at £550 each, £24,750—total, £54,089. For a test of the overhead system I take it that where the rails do not require renewal the existing track would remain undisturbed, excepting for the bonding of the rails; and for the overhead construction there would be iron tubular poles to carry the cross span wires where there are no buildings, and that where there are buildings the cross span wires would be fixed to them by ornamental rosettes, as at Hamburg, Milan, Coventry, and other towns. In that case I estimate the cost of overhead construction and rail bonding would be: 4½ miles double track at £1,212. 7s. per mile, £5,902 10s.; about two miles of the track would require relaying with new rails, and the stones redressed and relaid with requisite proportion of new stones, for this add, say, two miles at £4,706 per mile, £9,412—total for 4½ miles, £15,314. 10s."

Ealing.—Colonel W. M. Ducat, R.E, has held an enquiry concerning the District Council's application to the Local Government Board for permission to borrow £23,200 for electric lighting purposes. The Clerk (Mr. W Ruston) explained that a year or two ago the Local Government Board sanctioned a loan of £25,000 for electric lighting purposes, and in March last year sanctioned another loan of £7,000 for the same purpose. The original scheme was for the public lighting of the main roads, and for the supply of 5,000 private 8 c p. lamps. It was estimated that that number would be sufficient for the first three years, but so great had been the demand that at the present time—only 21 months after the works were opened—6,474 private lamps had already been connected, and the applications totalled to 9,000 lamps. In these circumstances, the Council had been compelled to make various extensions beyond the compulsory area, and it had been found economical to use electric light instead of gas in the streets through which the mains had been taken. He had, therefore, to ask the sanction of the Local Government Board to new electric lighting loans of £9,000, £6,000, £2,200, and £6,000, which would raise the total sum borrowed to £55,000. The Council asked that the repayment of the loans should extend over 30 years, or as long as the Board would grant In answer to the Inspector, the Clerk stated that the total amount actually expended, or for which the Council was liable, was £42,000. Replying to a further question Mr. Harris, consulting electrical engineer, said that the revenue of the Council from electric lighting from April 1, 1895, to March 31 last was £3,000. It was practically certain that this year the revenue would be £1,000 more.

Salisbury.—At the meeting of the Town Council the Town Clerk informed the meeting that he had received a copy of correspondence which had passed between the promoters of this company and the Board of Trade, and a request from the latter authority that the Council would transmit to the Board of Trade any observations they wished to make thereon. It appeared that the Board of Trade had written to the secretary of the Salisbury Electric Light and Supply Company, in a letter dated the 3rd ult., intimating, in reference to the Salisbury Electric Lighting Order, 1895, that as the undertakers had failed to comply with the provisions of Section 7 of that order it devolved upon the Board to consider whether they should not revoke the order. To this Mr. W. H. Gramshaw wrote, in reply, stating that the delay had arisen from several unfortunate circumstances which he had explained in a personal interview. He added: "We have, however, now made arrangements for carrying out the works. The contract will be for £14,000, of which the contractors take £7,000 in debentures. I can undertake the placing of £3,000 leaving a comparatively small sum to be subscribed. Under the circumstances we hope the Board of Trade will not proceed to revoke the order, but will give us such extension as they may think fit. We should suggest that the fulfilment of the obligations under Section 7 should be extended for a period of three months from the 1st June, 1896." In a further letter the Board of Trade replied that, subject to the concurrence of the local authority, whom they proposed to consult, they were prepared to defer the consideration of the question of the revocation of the order for a period of three months from the 1st inst. The Town Clerk said the Board of Trade wished to know whether the Council assented to the postponement of the question until September 1. The meeting gave its unanimous concurrence to the proposal.

Manchester.—Mr. Rienzi Walton, Local Government Board inspector, has held an enquiry into an application by the Corporation for power to borrow £100,000 for purposes of electric lighting. Mr. Alderman Higginbottom, chairman of the Electric Light Sub-Committee of the Gas Committee, stated that the electric works were originally laid down by Dr. John Hopkinson, and the system in use was the five-wire direct-current continuous under the Westinghouse patents All the later extensions had been carried out by the present resident engineer, Mr. Wordingham. The total money borrowed up to date was £250,000, and the whole of it had been expended in the construction of various works and machinery

Digitized by Google

and mains, in accordance with the details given at former enquiries. The demand for the electric current had been so great and was continuing at such a great rate that it was absolutely necessary to increase the plant and mains to meet the further demand. In 1893 the number of consumers was 82, and in June, 1896, it had increased to 1,216 The number of lamps in 1893 was 8,000, and in June, 1896, it had reached 109,636. About 7,100 lamps were still waiting connection, which would bring up the total to 116,700 lamps Even with the proposed extensions the capacity of the electric station was only equal to 136,000 lamps, so that only 19,300 lamps had to be added in order to exhaust the capacity of the present works. The Board of Trade had just given their consent to the area of supply being extended to the whole area of the city of Manchester, a distance of 7¼ miles from north to south, and of five miles from east to west, or an area of 20¼ square miles. It was quite evident that at an early date large extensions, or else a new station upon another site, would have to be begun to cope with the ever-growing demand for electric current for lighting, motive, and other purposes. The works from a financial point of view, had been a great success. Mr. C. H. Wordingham, chief electrical engineer to the Corporation, also gave evidence.

PROVISIONAL PATENTS, 1896.

JUNE 29.

14317. Improvements in electric tramways. James Enright, 202, Holland-road, Kensington, London.

14331. Improvements in and connected with electric tramways or railways. Andrew George Adamson, 154 St. Vincent-street, Glasgow.

14332. Improvements in apparatus for the use of electric light, gas, or oil for photographic, illuminating, and other purposes. Andrew George Adamson, 154, St. Vincent-street, Glasgow.

14367. An improvement in electro-deposition of metals and metallic alloys. Charles Arthur Hales, 19, Canonbury-villas, Canonbury, London.

14370. Improvements in electric arc lamps. Alfred Klotz, 18, Buckingham street, Strand, London

14376. Improvements in master clocks for operating or controlling circuits of electrical dials and similar instruments. George Bennett Bowell, 322, High Holborn, London.

14393. Improvements in anodes for electrolytic purposes. Peter Jensen, 77, Chancery-lane, London. (Henrik Christian Fredrik Störmer, Norway.)

14397. Improvements in electric arc lamps. Frederik Vilhelm Andersen, 40, Chancery-lane, London.

JUNE 30.

14442. Improvements in and relating to telegraphy. Samuel Van Buren Essick, 55, Chancery-lane, London. (Complete specification.)

14462. Improvements in or relating to systems of electrical distribution. Alfred Julius Boult, 111, Hatton-garden, London. (Gordon John Scott and William Smith Janney, United States.) (Complete specification.)

14463. Improvements in telegraphic alphabets. Samuel Van Buren Essick, 40, Chancery lane London. (Complete specification.)

14464. Improvements in telegraphy. Samuel Van Buren Essick, 40, Chancery-lane, London. (Complete specification.)

14500. An improved call counter suitable for telephone exchanges. Franz Stock, 18, Buckingham-street, Strand, London. (Complete specification.)

JULY 1.

14551. Securing so-called "caps" or "collars" to the necks of incandescent electric lamp globes. Francis Harrison and Isaac Probert, 25, Union-road, Clapham, London.

14554. A buoy that can be sunk or raised electrically from a distance. Siemens Bros. and Co., Limited, 28, Southampton-buildings, Chancery-lane, London. (Siemens and Halske, Germany.)

14555. Improvements in the process and apparatus for the papering of iron sheets for electrical and magnetical apparatus. Siemens Bros. and Co., Limited, 28, Southampton-buildings, Chancery-lane, London. (Siemens and Halske, Germany)

14584. Improvement in or connected with the arrangement and attachments of electrolytic anodes. Pierre Eugène Secrétan, 6, Lord-street, Liverpool.

JULY 2.

14613. Improvements in telephonic transmitters. Alexander Marr, 70, Market-street, Manchester.

14639. Improvements in apparatus for the production of electricity from the waste heat of gas, steam, or other heat engines. Herbert John Dowsing, 24, Budge row, London.

14641. Improvements in electric gas lighters. Gustav Byng, 73, St. Stephen's-road, Upton Park, London.

14642. Improvements in and connected with electric bells, gongs, and the like. Max Byng and Francis George Bell, 73, St. Stephen's-road, Upton Park, London.

JULY 3.

14766. Improvements in or relating to sockets or holders for incandescent electric lamps, and the attachment of lamps thereto. Eduard Worringen, of the Firm Constantia Incandescent Lamp Manufactory, 111, Hatton-garden, London.

JULY 4.

14846. Improvements in conducting contacts with carbon or other non-metallic electrodes. Siemens Bros. and Co., Limited, and Dr. Eugen Obach, 28, Southampton buildings, Chancery-lane, London (Complete specification.)

14848. Improvements in or connected with electric induction coils and transformers. Alfred Apps, 433, Strand, London.

14872. Improvements in telephone exchanges. Salomon Berditschewsky-Apostoloff, 53, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

NOTES.

Obituary.—The death is announced at Bonn of Prof. Friedrich August Kekule, the chemist, at the age of 67.

Lord Kelvin.—The London *Gazette* contains the official announcement that the Queen has conferred the Knight Grand Cross of the Royal Victorian Order on Baron Kelvin.

Gas Tramcars.—They are going to try gas-motor tramcars at Blackpool, and the opening show took place last Saturday. As they have already an electric tramway there on the conduit system, it will be interesting to compare results.

Tramways Institute.—The annual dinner of the Tramways Institute of Great Britain and Ireland is to be held at the Holborn Restaurant on Friday, July 31. The Right Hon. C. T. Ritchie, President of the Board of Trade, is to be one of the guests.

Telephones in Spain.—The series of articles against the interurban telephones continues in *El Telegrafista Español.* The main trouble appears to be that the interurban telephones take away custom from the Government telegraphs, and hence profit from the State. The Spanish public, however, do not appear to be equally indignant with the companies for stretching their concessions when it results in a cheap and convenient service.

Lightning.—It is stated that during last week's storm an ash tree on the common at Elmham, in Norfolk, was struck by lightning and the trunk split right through the whole way down. The base of the tree was rotten and was set on fire. The "Reeve of the Common"—a mediæval kind of a name to linger in a Norfolk parish—had the tree cut down. A curious point is that the foliage of the tree is said to have appeared quite unhurt.

Thief Detecting.—They are up to date at the Roman Catholic church at Folkestone, and put electric alarm bells in connection with the alms-boxes. A gentleman named Charles Smith, who wished to take the distribution of the alms into his own hands, was promptly caught last week in this way, and the local Bench gave him two months'. The report adds that he wore a false beard, though how that should assist him in robbing alms-boxes does not appear.

German Electro-Chemical Society.—The annual meeting of the Deutsche Elektrochemische Gesellschaft took place at the end of last month at Stuttgart. Prince Hermann of Saxe-Weimar-Eisenach was at several of the sittings. About a hundred members of the society attended. Among subjects discussed were the Kellner process, electrolytic dissociation, measurements (including the measurement of very high resistances), and the Röntgen radiations.

Coast Telephones.—It is stated that the Government intend to at once push on the completion of the coast telephonic communication in the Bristol Channel, and engineers are now engaged in setting out the last route of wires from Ilfracombe to Lynton. The system has been found most useful, especially during heavy gales and notifying ships in distress, while the connected coastguard will have the whole of the look-out stations in the Bristol Channel under their command.

Tramways and Street Cleaning.—Mr. A. J. Reynolds, a New Englander who has emigrated to Canada, has invented an arrangement for street cleaning to be worked in connection with electric tramways. The idea is to sweep the streets cross-wise, leaving the sweepings on the tram tracks. Mr. Reynolds's sweeping car then comes along, picks them up with rotating brushes, boxes them, and carries them off. It is stated that the Montreal Street Railway Company intend to give the plan a trial.

Presentation.—Last Friday evening a very interesting meeting was held in Ediswan-buildings of the sales staff of the Edison and Swan Company, when Mr. C. M. Downie presented a handsome marble clock to Mr. A. H. Hunt, of the company, on the occasion of his marriage with Miss Agnes Chapman. Mr. Downie, in a short speech, complimented Mr. Hunt upon his past services, and expressed the hope that in his future matrimonial state he would be as successful as he had been in his business capacity.

Spain.—According to the *Revista Tecnológico-Industrial*, electric lighting is making steady progress in Spain. Among a list of new installations it may be noted that at Ecija, Cieza, and Carbellino, water powers are to be utilised. Eight other places are mentioned as having work either in progress or just completed, with a view to electric lighting. At Nájera, in Logroño, it is proposed to put down an electric tramway between the town and the railway station at Cenicero, as well as to light various villages on the route.

Electricity in the Nursery.—A note in *L'Elettricità* says that a Frenchman has discovered a new use for electricity, and has invented an arrangement by which the cries of a baby are received in a microphone placed in the cradle over the infant's head, and by some intermediate mechanism not described start the current in a circuit containing an electric bell. The mother or nurse can thus be summoned from any distance. Unless we are mistaken, our Milan contemporary described something of the same sort at much greater length nearly nine months ago.

Personal.—Mr. Vesey Brown, the electrical engineer for Sunderland, has decided to accept a similar appointment offered him by the Lincoln Corporation. At the last meeting of the Sunderland Corporation a motion increasing Mr. Brown's salary by £90 at once, and promising a further increase of £50 at the expiration of the year provided he would enter into a three years' engagement, was passed. Mr. Brown, however, has decided to go south. Though he will be required in Lincoln almost immediately, he will superintend the electrical extensions about to be carried out in Sunderland. Mr. Brown is a nephew of Lord Kelvin.

A Chicago Accident.—According to the *Western Electrician*, a couple of firemen, in endeavouring to extinguish some waste that had caught fire in the basement of the power-house of the Chicago City Railway Company, sustained severe shocks from current conveyed along the stream of water. They were rendered unconscious, but soon recovered. It will be remembered that some time ago a scheme was imputed to Mr. Edison by which the stream of water from a fire-engine was to be rendered additionally unpleasant to those it hit somehow in this way, but the public were never favoured with the details, the working out of which to an ordinary engineer would present some points of difficulty.

Telegraphs in Rhodesia.—Captain Roach, who is in command of the Salisbury-Tete section of the Trans-continental Telegraph Company's construction party, has been giving some particulars of his work to a Cape Town interviewer. His chief difficulties have been in the transport of materials, the tsetse fly prohibiting wagon transport beyond certain points. So everything has to go on the heads of Mashona and Zambesi "boys." Iron poles are used which, unless jointed, seem awkward things for native carriers in a rough country, and some of the country between Salisbury and Tete is very rough. However, they are better than wood, and prevent the necessity of coming to some sort of an arrangement with the wood-eating insects. Lastly, there was the country fever, which the construction party did not escape.

Digitized by Google

Submarine Boat.—Mr. C. Seymour-Allen is reported to have designed an electrically-propelled submarine vessel, which has got as far as a 6ft. model exhibited in a swimming-bath. The new boat is called a submarine torpedo vessel and blockade runner, and the inventor says that it will be possible to remain under water, not for hours merely, but for weeks and months at a time. Compressed air is to be stored for breathing purposes, and "the motive power is electricity." This looks like accumulators. Storage batteries are very nice things, but everyone would not care to be shut up with one in an airtight boat under water for "weeks and months at a time." However, they do not consume air or vary in weight, which are great virtues in submarine work.

Telephones in Abyssinia.—A paragraph has been going the round of that portion of the Press that knew no better describing Abyssinia as having an amount of telephonic communication which might easily put some European and civilised countries to shame. The paragraph was absurd on the face of it to anyone who knew anything of Abyssinia and the state of things prevailing there. The report, however, was not absolutely baseless, for it appears that a Brussels electrician did receive an order for telephones for King Menelek's "palace," and actually went out to execute it. Probably the rest of the report arose from some slight confusion between what the enterprising Belgian actually had done and what he fully intended to do in the matter of educating the Abyssinian in the ways and wants of European civilisation.

Proving a Fracture.—Röntgen photographs have been accepted in an assize court as evidence in the matter of an actress's ankle, but now they have descended to the county court. At the Liverpool County Court on Monday a dock labourer sought to recover, under the Employers' Liability Act, £150 from Messrs. T. and J. Harrison, shipowners, for personal injuries. The liability was admitted, and the only question was the amount of compensation. The plaintiff was knocked down by a boom and his arm broken. In order to show the nature of the fracture, photographs of the injured arm, taken by Dr. Buchanan by means of the Röntgen rays, were produced. Counsel objected, but the judge admitted the photographs, their authenticity being proved in the usual manner. Possibly the jury might have preferred a gratuitous exhibition of the cryptoscope screen in a dark room; but they gave the plaintiff £60 damages.

Discharging Effect of Light.—Prof. Warburg, speaking at the Berlin Physical Society, maintained that the action of ultra-violet rays in facilitating sparking and the discharge of negatively electrified bodies consists in doing away with the retarding force which, according to Jaumann's researches, exists at each discharge. Gases, unlike metals whose conductivity is independent of strength of current, only become conductors when the current has reached a certain intensity; hence possibly during the retardation the gas is becoming a conductor, and if so, the action of light consists in the removal of some obstruction to the establishment of conduction. All of which, if it comes to anything at all, only means that if a system in stress is just about to break down, any vibration accelerates the catastrophe. But really very little is known about it. Nor is it any answer to the question why the effect is different on positive and negative charges, so far as ordinary ultra-violet light is concerned, while the Röntgen waves show no preference in the matter.

Royal Society.—At the Hôtel Metropole on Tuesday the Royal Society entertained at dinner the foreign delegates to the international conference convened for the purpose of forming a catalogue of scientific literature on principles which shall be universally accepted. The chair was taken by Sir Joseph Lister, P.R.S., and there were also present, among a large number of distinguished guests, the following whose names will be familiar to electrical readers: Sir F. Abel, Prof. Armstrong, Prof. Ayrton, Sir F. Bramwell, Sir W. H. Flower, Sir D. Galton, Dr. Gladstone, Sir John Gorst, Prof. Greenhill, Prof. J. V. Jones, Lord Kelvin, Prof. Liversidge, Mr. Lockyer, Mr. Preece, Lord Rayleigh, Prof. Roberts-Austen, Prof. Rücker, Sir Gabriel Stokes, Prof. Unwin, and Prof. Van't Hoff. Sir John Gorst represented the British Government, and the agents-general for most of the important colonies were there, while the presence of ambassadors and foreign ministers showed that foreign governments are in many cases less backward in recognising the claims of science than our own. There was a reception the day before at Burlington House; but one list of names at a time is enough for a note.

British Association Meeting.—During the meeting of the British Association in Liverpool, in September, a number of the owners of works of manufacturing and engineering interest will open their establishments for inspection. The half day excursions on Saturday, September 19, include: (1) River excursion with the Mersey Dock Board; (2) overhead electric railway; (3) Speke Hall, Hale Hall, etc.; (4) Thurstaston, Storeton Quarry—where the reptilian footprints are found, and the Leasowe submarine forest; (5) Bidston Observatory; (6) Chester and Hawarden; (7) dredging excursion with the Lancashire Sea Fisheries steamer. Whole-day excursions on Thursday, September 24: (1) Chester and Eaton Hall; (2) Rivington Waterworks, etc.; (3) Llandudno and Beaumaris by sea; (4) Manchester Ship Canal, etc.; (5) Prestatyn, Tremerchion Caves, and Corwen; (6) Northwich, Weaver Navigation, and Delamere Forest. At the end of the meeting there will be longer excursions, extending over several days, to the Vyrnwy waterworks in Wales, and to the English lakes; and a specially scientific excursion to the Isle of Man, for which a separate programme has been prepared, covering five days—Thursday to Monday inclusive.

South-West London Polytechnic.—In the course of the nine months since this institution has been opened, about 1,400 students have availed themselves of the educational advantages to be obtained within its walls. Up to the present time, with the exception of the art department, the work has been mainly in the evening; but at the suggestion of the principal, Mr. Herbert Tomlinson, F.R.S., and aided by a grant from the Technical Education Board of the London County Council, the governing body have wisely decided to throw open the workshops, laboratories, and classrooms to day students. The scheme of the day classes is to be that of the Finsbury Technical College, which has now stood successfully the test of years. There will be no overlapping between the work of the institute and the Central Technical College in Exhibition-road, inasmuch as one of the objects of the present scheme is to render the South-West Polytechnic a feeder to the Central Technical College. The institute is provided with two chemical laboratories, affording accommodation for about 60 students working at one time, two physical laboratories accommodating between 40 and 50 students at once, and two mechanical laboratories, as well as also workshops for various trades. The institute is lighted throughout by electricity, and the electric light and plant are available for experimental purposes.

Wind Power.—A paper which Mr. E. O. Baldwin, of Dixville, Quebec, read before the Netherlands Society for the Promotion of Industry at Haarlem is published in the *Canadian Engineer*, and deals with Mr. Baldwin's attempts

Digitized by Google

to utilise the power of the wind for producing current. They are strong at windmills in Holland, where they use them for pumping purposes, but the difficulties in the way of getting a useful supply of current are much greater than when the only work required is to lift water a short distance and speed regulation is of no importance. Mr. Baldwin's regulating apparatus consists of an additional coil on the field magnets to act as a demagnetising coil, and an electromagnet which attracts a pivoted iron arm against the resistance of a spring and throws the demagnetising coil into the field circuit whenever the voltage rises above the desired point. There is a very rapid vibration of the arm, and Mr. Baldwin states that he can adjust the regulation so that lamps can be run directly off a dynamo belted to the windmill without any perceptible flickering. Normally, however, a storage battery is used. There is, however, with every deference to Mr. Baldwin, a much more important question to be solved than that of regulation—namely, what is to be done in a period of calm. Accumulators on a large scale are expensive, and the decline and fall of the wind-driven flour-mill is not a hopeful augury.

Sarajevo. — One result of the "occupying and administering" of the provinces of Bosnia and Herzegovina by the Austrians is that Sarajevo has been supplied with a system of electric lighting and tramways. The current for both of these is supplied from one generating station. The installation was done by Siemens and Halske, and a description of it given at the Vienna Electric Engineering Association by Mr. Ludwig Spängler has been reprinted in the *Zeitschrift für Elektrotechnik.* From this it appears that the lighting is on the three-wire continuous-current system at 110 volts. Accumulators are used in the distribution, so that a voltage of from 300 to 350 can be dealt with, and in this way it becomes possible to use "one and the same engine for both lighting and tramway work." There were originally three engines of from 150 h.p. to 190 h.p. each, but an additional one of 300 h.p. is to be provided with a view to extensions. Private lighting is provided for on a basis of 6,500 16-c.p. lamps, and there are 765 incandescent and 36 arc lamps for public lighting. The tramway is on the overhead system with return through the rails. For the passenger traffic there are five motorcars and eight trailers. An electric locomotive is provided for the goods service. The combination of lighting and tramway work enables a larger type of machine to be used than would otherwise be possible, only one of the engines being run in the daytime. It is claimed that considerable economy results, and Mr. Spängler thinks that such systems of combined lighting and tramway work have a great future before them in providing for the necessities of comparatively small towns, and therefore deserve particular attention. No figures or details of working are, however, available by which to judge the results attained.

Motorcarts.—There is to be a motorcart race from Paris to Marseilles and back on October 1 of the present year. The race has been arranged by the Automobile Club of France. The posts of honorary presidents of the committee of arrangement are filled by Messrs. Marcel Deprez and Georges Berger, that of president by Mr. Edmond Recope. Mr. Henri de la Valette acts as secretary. It is reported that the Lord Provost of Aberdeen has been trying a motorcart. It was an oil-motorcart, but it indicates that the authorities of that northern borough have reasonable ideas as to the propriety of enforcing an obsolescent statute. It is a pity that the same views do not prevail elsewhere. Meanwhile the legalisation Bill has got into the Standing Committee on Law, and last Friday Mr. Chaplin carried an amendment there fixing the maximum weight for motor-carriages at three tons unladen. A subsequent amendment provides that the weight of "water, fuel, or accumulators used for propelling the vehicle" is not to be included in this weight. That is good for electric motorcarts, and not bad for steam, but the steam-cart has got to make its exhaust invisible. So far as the roads are concerned, it would have been almost as well to have left the maximum weight at four tons "all on," and would save disputes. Lastly, Mr. Griffith Boscawen moved a new clause providing that Sub-section 4 of Section 28 of the Highways and Locomotives Amendment Act, 1878, might be from time to time varied by the Local Government Board. The sub-section specifies a particular pattern of driving wheel to be used on locomotives on roads, and this pattern had been found to be most injurious to many roads. The clause was added to the Bill, and it was ordered to be reported with amendments to the House. The Britannia Motor Carriage was shown privately at the Imperial Institute on Wednesday.

Closed-Conduit Tramways.—The New York *Electrical Engineer*, in the course of an article on the Johnson-Lundell system tramway, which has been running in West Thirty-fourth-street, New York, for about four months, gives some details as to the amount of leakage from the contact points which may be worth notice. After a description of the circuits and electromagnets used to make those contact-pieces under the car "alive" the article proceeds: "When no car is running, and consequently no contact points are alive, there is absolutely no leakage possible on the system in any kind of weather, owing to the high insulation of the main conductor and switch magnets. There is also no leakage in dry weather when the cars are running. It is readily seen that when any leakage does occur it can only be at the point directly under a car where the contacts are alive. During a rain storm, or immediately after, the leakage from a positive contact point is about a quarter ampere, and from the whole contact bar about one ampere. The greatest leakage appears to be due to snow and slush during the winter, but no accurate data could be secured owing to the difficulty of taking readings while the car was running on a crowded street. On the day after a heavy snowstorm when the track rails and contact points were entirely submerged in water and snow, the leakage from the positive contact bar appeared to be only from three to five amperes." It should be stated that the voltage is 500. It may also be added that each car carries a storage battery consisting of 200 cells of small capacity, divided into halves and placed under both ends of the car beneath the floor. This battery is used on starting the car only, except when it may be called into use by some emergency. Its function is to start the switch magnets, making the contact points "alive" when the car is standing still and the switch magnets are all open.

Industrial Chemistry.—The fifteenth annual meeting of the Society of Chemical Industry was opened on Wednesday at Carpenters' Hall, London-wall. The society's medal "for conspicuous services rendered to chemistry by research, discovery, invention, or improvement in processes, irrespective of membership," was awarded to Mr. John Glover, the inventor of the Glover tower. Mr. T. Tyrer delivered the presidential address, and in the course of it remarked, in comparing English with Continental work, that the conclusion he had arrived at was that the real cause of the progress and prosperity of German chemical industries was to be found in the superior qualifications of the directing minds there. Again, the Austrian Government did all it could to promote industry, and

Digitized by Google

especially chemical industry, whereas in England, where the Government could readily obtain and spend £18,000,000 on armaments, £4,000 only went to the endowment of research. With the resources of this wealthy country, and the public spirit of its citizens, we ought to remain very little longer in the present state of obvious backwardness. Our elementary training was defective, but we looked forward to the time when the State and public bodies should here, as in Germany, foster our industries by a sound system of education—even in economics for the leaders of the workmen. It would undoubtedly be very nice if Mr. Glover's suggestion could be carried out. Unfortunately, there are so many people that carefully abstain from understanding an argument if they are afraid that it leads to conclusions that are distasteful to them. Try, for instance, to demonstrate to a trades union leader that, as a rule, strikes do not pay, or to a manufacturing member of Parliament that there are other things to be considered besides so organising industry as to do things 1 per cent. cheaper than the foreign competitor. As a matter of fact, there is nothing more disappointing to believers in progress than the way in which the reasoned conclusions of political economy have been thrown aside by leaders of all parties of late years. In the evening many of the members of the society were entertained by the Lord Mayor and Lady Mayoress at a reception at the Mansion House, where they met the president of the Royal Society (Sir Joseph Lister) and the members of the International Conference on the Classification of Scientific Literature. Among those present were Mr. Norman Lockyer, Prof. Jebb, M.P., Prof. Michael Foster, Prof. Roberts-Austen, Dr. and Mrs. L. Mond, Mr. and Mrs. A. Siemens, Prof. C. Lapworth, Prof. A. W. Rücker, Prof. A. B. W. Kennedy, and Mr. W. Huggins.

Arc in a Magnetic Field.—Mr. J. B. Hall has described in the *Canadian Engineer* some experiments he made on the effect of running an arc in a magnetic field. An "anchor-ring" core electromagnet with a gap in it appears to have been used, the carbons being arranged in the air-gap parallel to the direction of the lines of force and in the centre of the field. The current passed first through the magnetising coil and then to the arc. Cored carbons were used, and, from the diagram given in our contemporary, the arc was a horizontal one: "The first test was the starting of the arc uninfluenced by magnetism. It burned quietly, with the carbon anode assuming the usual crater-like form. The distance between electrodes being about $\frac{5}{16}$in., the heated currents of air caused it to move from side to side. The current was 9·5 amperes and 51 volts. Then the arc was started influenced by the field, having a strength of 250 C.G.S. lines, the carbons being so placed that the axis of the arc was parallel to the lines of force. It was very noisy, and the arc spread to the outer edge of the anode (leaving the inner core untouched), in the form of an inverted cone, numerous points of light brighter than the rest of the arc being seen, while the flame rotated in the direction of the flow of current in the coil. The carbon was consumed very slowly in proportion to what was burned in the uninfluenced arc, and the apparent temperature of the arc seemed one-half of the uninfluenced arc. The resistance in the gap between the electrodes decreased so that the current passing was 11·2 amperes and 47 volts. (The primary voltage was 110 volts, current from an incandescent circuit being used, with stationary water resistance interposed to reduce the voltage.) The arc at the cathode narrowed down to a very fine point, never wavering, and remaining in the same place. The field was increased to 500 C.G.S. lines and the effects were only augmented, the rotation being more rapid, the noise louder, and the resistance decreased until 14 amperes at 42 volts were passing. The field was then increased to 1,000 C.G.S. lines and the noise became a roar, the arc curled out and around the anode's outer edge, yet maintaining a point at the cathode; the current became 20 amperes at 34·5 volts; its rotation was no longer visible, and the points of light dispersed over the edge of the anode, multiplied until it bore a resemblance to 'stipple' work." Subsequently, the positive carbon was placed crosswise to the field, and consequently at right angles to the negative carbon, when it is stated that, with a field of 1,000 C.G.S. lines, "the arc started around the anode until it reached the other side farther away from the cathode," and the current fluctuated rapidly. No measurements beyond those embodied in the extract quoted are given, nor is the direction of the winding stated, but further experiments are promised.

Brooklyn Tramways.—It is well known that the working of the Brooklyn tramways has been made use of by the enemies of electric traction for the purpose of discrediting that system. It is therefore well to know the cause of the numerous accidents there. The New York *Electrical Engineer*, which is in a position to know all about it, says, "The city of Brooklyn has had, perhaps, more fatalities than any city where the trolley system has been introduced, but most, if not all, of these accidents have been due to the carelessness of individuals or the running of cars at too high a speed." In certain parts of Brooklyn, where lines from numerous directions converge to several centres, and where traffic is extremely congested during certain hours, both pedestrians and motormen can only avoid accidents by the use of extreme caution. A recent accident, however, cannot be referred to this cause, as it was occasioned by the running away of a car backwards on a down grade. "From every account which has been published," says our contemporary, "it seems apparent that the motorman was far less to blame than the conductor and the equipment of the car, for which the company is responsible. In the first place, the car was crowded far beyond the limit of safety, and it certainly comes very close to criminal negligence to permit 133 passengers to ride on a car that was built to carry 50 people. When a car is overcrowded in this way it almost always happens that most of the crowd is concentrated near the rear of the car. This takes the weight off the front wheels, so that even if they are stopped by the brake it has but a small effect on stopping the car if the grade is considerable. The use of heavy cars of extra length, which are run at the rate of 15 miles an hour or more at some points of the road, is entirely incompatible with the use of hand-brakes of any description, and they are particularly inadequate in the case where heavy grades are to be encountered. Apparently the company realised this fact, as it had adopted the primitive method of stationing two men at the dangerous grade armed with planks to throw under the wheels of runaway cars. What is really needed in this case is a power brake. As a matter of fact, the brakes on trolley cars in general have never kept pace with the requirements of the latter. While the weight and speed of trolley cars are greatly in excess of that of any horse-car, the same brakes are frequently used indifferently on both cars, the extra power necessary for the trolley car being supplied by the motorman. On a road where heavy grades occur, emergency brakes of some kind are almost indispensable, and emergency brakes should be applied to the car in such a way that both they and the ordinary hand-brakes co-operate independently. This precaution is required in case of the disablement of either one, as was the case in the

Digitized by Google

accident above alluded to." In general there is plenty of space in American streets, but the distances are great, and consequently a high speed is sure to be the rule. Moreover, there is room to get out of the way. Where, however, this does not happen to be the case, it would have been well from every point of view to adopt a slower and more European way of working the traffic. It is right to go ahead whenever possible, but it must not result in running violently backwards.

Temperature and Insulation.—Mr. C. E. Skinner's investigations of the effect of temperature on insulating materials, and especially such as are used in the construction of dynamo and motor armatures, have been summarised in a communication to the American Institution of Electrical Engineers. The results have been mentioned before, but not the apparatus used. A series of tests were undertaken to determine the effect of temperature on the insulation resistance and breaking-down E.M.F. of various insulating materials and also of completed apparatus, and a large number of insulating materials, including paper, cloth, etc., both in the treated and untreated forms, were tested. For testing materials the apparatus finally adopted consisted of two similar plates, between which the insulating material is placed when tested. These plates are 10in. in diameter, and are carefully surfaced. Each part is made of two separate pieces of cast iron, fastened together, and wound with a coil of asbestos-covered wire. The heating of the apparatus is effected by sending an alternating current through the two coils in series, and results from the eddy-current and hysteresis loss in the iron, as well as from the copper loss in the coil. The rate of heating can be controlled easily by means of a suitable rheostat in circuit with the coils, the mass of iron in the heater being sufficient to prevent sudden changes of temperature from outside causes. The insulation resistance of the samples was measured in all cases by means of a high-resistance voltmeter on a 500-volt circuit, all wires of the heating circuit being disconnected when the insulation measurements were made. A curve was obtained from tests on a piece of untreated paper. The minimum resistance was reached at slightly below 100deg. C. From this point the resistance rises rapidly until it reaches a point too high to be measured with the apparatus used. The absolute value of the insulation resistance of any material of this class depends on the amount of moisture in the material at the start, the rate of heating, and the chance for the escape of moisture during the test. The absolute value of the insulation resistance of treated material depends largely on the drying of the material before treatment. Samples of cloth which were treated with linseed oil after being thoroughly dried and then the oil baked on do not at any time show a very low insulation resistance, even at a temperature of 150deg. C. No relation could be found between the breaking-down E.M.F. and the insulation resistance, for though a low insulation resistance usually meant a low breaking-down test, a low breaking-down test did not necessarily mean a low insulation resistance. Mr. Skinner's conclusions are that (*a*) the insulation resistance of all ordinary fibrous insulating materials, such as paper, cloth, etc., decreases upon being heated up, and then increases again when the moisture is expelled; (*b*) continued heating of 31 hours at 120deg. C. does not lower the insulation resistance of paper; (*c*) the insulation resistance of completed apparatus shows the same characteristics as the insulation resistance of materials taken separately; (*d*) a low insulation resistance is not necessarily an indication of poor insulation, but probably an indication of the condition of the apparatus in regard to moisture; (*e*) a high E.M.F. should not be applied to apparatus when the insulation resistance is low; (*f*) material which is badly deteriorated mechanically by heat may still have a high insulation resistance, but very poor insulating qualities.

Rontgen Radiations.—The annual meeting of the Victoria Institute was interesting as being the occasion of the expression by Sir Gabriel Stokes and Lord Kelvin of their views on the theory of the Röntgen radiations. Sir Gabriel Stokes dealt with the subject in his presidential address. He had never himself made experiments with the Röntgen rays; but he had followed closely what others had done, so that he could not but think that he had a tolerably good idea of the nature of these rays, and had arrived at the conclusion that they were, like ordinary light, due to transverse vibrations, but of excessively high frequency. As was indicated in these columns in the early days of the discovery, there seems no other explanation possible, since it was clear that if longitudinal vibrations were transmissible in air, they must be constantly produced, and it would not be possible to keep a sensitised plate in an ordinary cardboard box. It is therefore satisfactory to know from a mathematician of Sir G. Stokes's eminence that there are no insuperable theoretical difficulties in the way of its acceptance. Lord Kelvin, who moved the vote of thanks for the address, said Sir G. Stokes had gone into a very full and most interesting and important statement regarding one of the greatest discoveries of this century, but all that he had touched upon was full of contentious matter. The scientific world had been gravely agitated upon this subject since the beginning of January, and almost every sentence uttered by Sir G. Stokes was strongly in opposition to a great deal that had been published by many exceedingly able men, both mathematicians and experimenters. Personally he had listened with the greatest possible satisfaction and comfort to the declarations of Sir G. Stokes. When he heard Sir George declare for transverse vibrations, and the strong reasons put forward for that conclusion, he felt himself very strongly fortified in accepting it. They must not, however, forget that what had been put before them had not been absolutely demonstrated. Whilst Sir George Stokes had tantalised their minds very much by leaving them open to the possibility of some other explanation, he had certainly left them with the impression that it was exceedingly probable that the Röntgen rays consisted of transverse vibrations, but a hundredfold more frequent in a second of time than the transverse vibrations of ordinary visible light, so that if there were about seven hundred million million vibrations per second in green light there must be seven hundred hundred, or seventy thousand, million million vibrations of the Röntgen rays per second. Mathematicians and experimenters who knew the properties of light felt very much astonished to think that exceedingly sharp impact of the electrified particles proceeding from the cathode and striking against a target should produce vibrations of hundred times greater frequency than the luminiferous vibrations of all the qualities of light previously known. They must all feel that the curtain had been drawn from before their eyes, and that they had been allowed to look into some of the mysteries of Nature. If Lord Kelvin says so, no doubt it is as he says. But it is not very clear why anyone should be astonished at the possibility of an atom or a molecule producing vibrations which are not large compared with its own size, and that is really all that is required. As to the "luminiferous medium," it properties are simply whatever happens to be wanted to explain the phenomena, and therefore it may be conceived capable of transmitting "waves" of any minuteness.

THE 1896 MEETING OF THE VERBAND DEUTSCHER ELEKTROTECHNIKER IN BERLIN.

(BY OUR SPECIAL CORRESPONDENT.)

(Continued from page 37.)

The arrangements for Friday, the 19th of June, were all of the sight-seeing order. The quantity and quality of the sights depended only on the appetite of the individual. Thus the programme commenced at 9 a.m. with a visit to the electrical laboratories of the "Reichsanstalt"; from there the members proceeded at will to either or all of the following: the old and new works of the Allgemeine Elektricitäts-Gesellschaft; the works of Mix and Genest, the noted telephone manufacturers; and the Mauerstrasse station of the Berlin electricity works. After this heavy fare came a visit to the Berlin Exhibition, which was terminated at 7 p.m. by a gathering in the adjoining show, called "Kairo," where the usual Earl's Court performances were to be seen. I commenced well, but must admit that the fare was too abundant and that I did not conform to the full programme.

The electrical and physical laboratories of the Reichsanstalt, which are under the able superintendence of Prof. F. Kohlrausch, are situated at Charlottenburg. The history of the institution is somewhat as follows. In the early days of electric lighting work, Dr. Werner Siemens recognised the need of having an authority on electric standards for technical purposes which should be above suspicion. He rightly considered that such an authority would tend to uniform standards of current, voltage, and resistance being worked so throughout the empire, and that tests carried out by such an authority would settle at once any quantitative technical matter in dispute. He therefore gave the large site and a good proportion of the cost of erecting and equipping the laboratories we visited, on the understanding that the Government would support the institution and vest it with Imperial authority. The institute is therefore used largely for research work, and also for testing and calibrating commercial meters, etc. It is not endowed for educational purposes, although a number of young men do attend to assist the various professors in their work. The nearest approach to a similar institution in England is the small laboratory established at the Board of Trade office, Whitehall, by Major Cardew. This latter place, although not equipped for extended research work, is in my opinion quite as useful to the practical man for all purposes of reference.

We were shown round the laboratories of the Reichsanstalt by Prof. Feussnee and Dr. Lindek, who most carefully explained the various instruments in the different departments. I was impressed by the care shown over details. Thus the standard resistance coils for use on the potentiometer methods, to which Dr. Lindek has devoted so much attention, are immersed in oil baths. The oil in each vessel is churned by small screw propellers driven by means of fine catgut from a small motor. Thus a perfect circulation of oil is obtained and the cooling of the coil, if a moderate current is passing, is accelerated, so that the temperature of the oil gives practically that of the conductor immersed in it. The small accumulators used to give high voltages for calibrating voltmeters, etc., were beautifully arranged on hanging shelves. These shelves consisted of a tall vertical rectangle of strip iron with a series of horizontal braces across it. These formed the shelves on which the cells were supported. The usual insulation devices were provided by paraffined wood laid on insulators. The whole rectangular section thus built up hung on rollers at the top. Each rectangular section had 20 shelves, and each shelf was equipped with 25 small accumulators in series. This gives about 50 volts per shelf, so that the voltage when all are in series is about 1,000 volts. Ten of these sections are now provided, but they are not yet completely equipped with cells. The whole of the ten sections are enclosed in a glazed partition with folding doors. Thus, when any cell needs attention, its section can be pulled out, as it runs on the rollers mentioned above.

The meter-testing department was very well provided with meters of practically every type on the market. The arrangements for supplying current to them from either direct or alternating current dynamos, or from accumulators, were well and conveniently designed.

I heard a few facts about the bearing of this institution in the matter of electric railways which seemed of interest. It is the old story, "One touch of nature makes the whole world kin." An electric railway was projected which was to run through the Thiergarten and pass through Charlottenburg, not far from the Reichsanstalt. The heavy rails required for the traffic were laid, and a large amount of capital thus laid out. Then it was thought by the professors at the institute that their original researches in magnetism would be upset if such a line was worked electrically. Hence a series of objections to electric traction such as are kept in stock by the municipal authorities at Berlin (see the *Bier Zeitung*) were placed before the Government. As the institution is under Imperial control and influence it naturally gained the day, and electric traction on the lines in question was put back some years. The curious coincidence is that the firm of Siemens and Halske held the contracts or were working the scheme, and hence the Reichsanstalt was practically turning on its founder. The question as to whether such delicate magnetic observations are of supreme importance to the general profession is a moot point, but it is certainly my opinion that the general public would wish both the experiments and the experimenters to be subservient to the public convenience. In other words, the man who undertakes experiments which necessitate the retardation of the progress in his district becomes a public nuisance.

Leaving the laboratory, the bulk of the members of the Verband proceeded to the works of the Allgemeine Elektricitäts-Gesellschaft, which I hope to describe in my next article.

Interview with Mr. F. Ross, of Vienna, on a New Development in Accumulator Traction.

I found that Mr. Ross had taken an active interest in a system of accumulator traction now being used at Hanover and Dresden. This system is one which should commend itself to the English public, as with it the advantages of accumulator traction in the crowded parts of a town are available without undue increase in the running expenses. The system as explained by Mr. Ross is briefly as follows: The suburban portions of the lines are equipped with the ordinary overhead system, and each car is supplied with a set of accumulators. These are charged *in situ* when the car is running on the trolley wire. In the crowded or narrow streets, or in such places where the municipal consent to the erection of overhead wires cannot be obtained, the accumulators can supply the necessary current. In a town the proportion of the line which cannot be worked on the trolley system is usually not large, and hence the capacity and weight of the accumulator can be kept down much below that required for the complete accumulator traction system.

Mr. Ross informed me that in September last some half-dozen of these cars were started at Hanover, and the results obtained with them were so favourable that 40 more were ordered in November. A regular service is now maintained, some 35 cars being in use at one time. The engineer-in-charge at Hanover claims most advantageous results, even over the old costs, when the trolley system only was used. The expenditure in coal was less than before, due, as Mr. Ross explains, to the increased regularity of the supply from the power station. Thus, when the cars are on the suburban parts of the lines which are connected by the trolley wire to the supply station, the accumulators are working in parallel with the motors. In starting, the excess current required will be supplied to the motor by the accumulators. The charging current also will vary with the load on the motor, the general tendency of the variation being towards a constant current being taken from the line. The sharply-peaked curves now invariably found for the current output from traction stations will thus give way to curves having more gradual changes of smaller amounts. For a station supplying a few cars this change in the form of the curve is most marked, and will result in a comparatively large coal economy. For large stations, on

Digitized by Google

the other hand, Mr. Ross does not think the saving in coal will be very much. It seems that the lines at Hanover are very favourable to tramcar work, as the grades are nowhere excessive. Mr. Ross has been retained to report on the financial results of this undertaking for the Vienna authorities. As the figures he had by him were not complete, and at the same time were privileged, he was unable to furnish me at the time with exact details. The working expenses up to now have been favourable, but he considered that more lengthy experience was required before the true cost could be obtained. The accumulators certainly are treated in the best way possible to ensure a long life, as there is no great interval between the charge and discharge period. The great advantage which this system gives is well instanced by the facts which led to its adoption at Dresden. Mr. Ross told me that at this latter city the traction company was compelled by the municipal authorities not to use the trolley system in certain streets. Not content with this restriction, the authorities went so far as to specify whose conduit system was to be used. After looking into the cost of the conduit system to which they were to be bound, etc., the company decided to adopt the accumulator system as above. In this way no alteration was required to the track.

The terms under which the Dresden companies were licensed by the municipality are as follows: The central station, the feeders, and return cables, the trolley and conduit systems, were to be erected by the municipality, which furnishes all the current to the companies under the following method of charges: to the actual working expenses are to be further added 5 per cent. interest, 2 per cent. depreciation on the cost of the buildings, 7 per cent. on that of the engines and dynamos, 10 per cent. on the cost of the boilers. The amount so obtained is further increased by 20 per cent. to give the actual sum to be paid. Over and above this the companies have to pay 10 per cent. per annum on the cost of the overhead lines, etc., and 15 per cent. per annum on underground feeders and conduits. I need hardly say that these terms are exceedingly favourable to the municipality. The minimum price paid up to the end of 1895 has been 1·62d. per kilowatt-hour delivered from the central station.

Mr. Ross kindly gave me an introduction to Prof. Ullbricht, of Dresden, so that I was able to view the cars while at work. Another interesting advantage I found was that where two rival electric lines coincide for a few hundred yards, as they do at one place in Dresden, the car with accumulators can there be run over that section without taking current from the trolley wire of its rival. With the improvements now effected in accumulators, and their lowered cost, this system seems a practical method of dealing with a necessity in towns where the trolley is forbidden in certain streets. Mr. Ross assured me that electric traction was making great strides in Germany, and that the rapid transit resulting from its use gained great favour with the people. The appreciation of the advantages derived from it in Leipzig was so great that the authorities had insisted on having two tracks in all the principal streets. Thus in some narrow streets electric traction seriously interfered with the ordinary vehicular traffic (two tracks were put in a street under eight yards wide). It was considered that the public gained more by the increased facilities of the electric cars than was lost by private inconvenience.

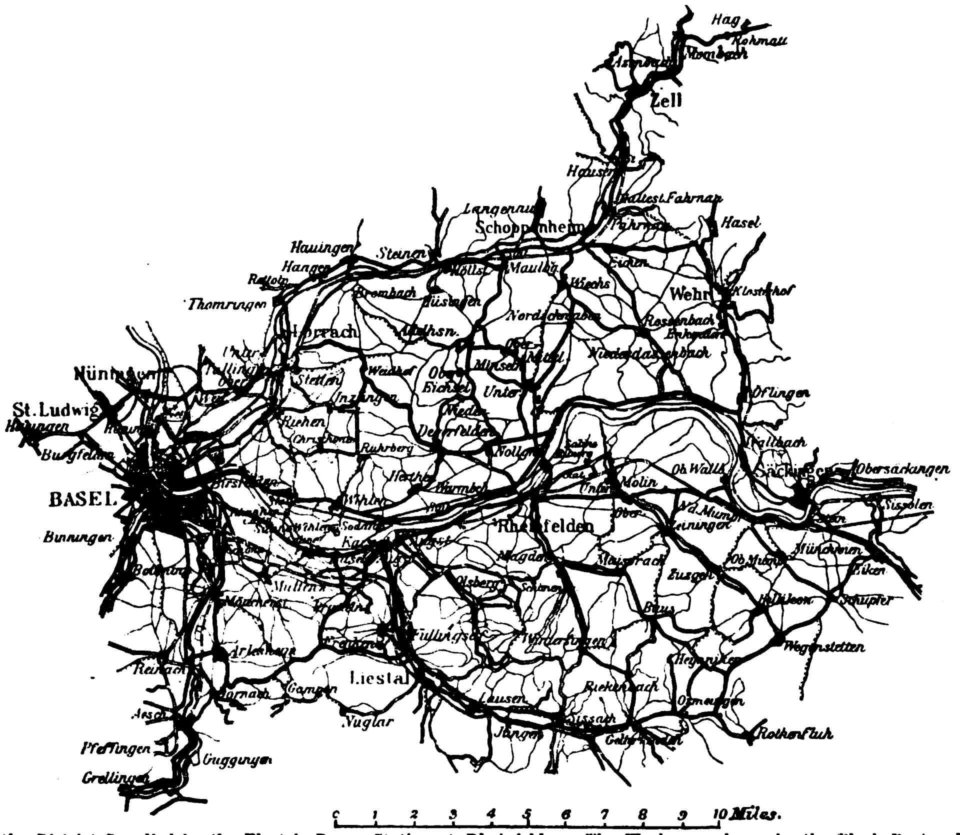

FIG. 1.—Map of the District Supplied by the Electric Power Station at Rheinfelden. The Works are shown by the Black Rectangles, and the Heavy Black Lines denote the Electric Mains

---

Works for Transmission of Power at Rheinfelden.

The following is a brief *résumé* of the interesting paper read by Director Rathenau on the above subject:

The works (Fig. 1) are situated on the Rhine near Bale, and were erected for the purpose of utilising the water power there available. There are three rapids at this spot, between the Lake of Beugg and the Rhine bridge, having a total fall of from 21ft. to 24ft. 6in. This fall, however, varies very considerably with the quantity of water coming down the river. The available head at the turbine is that of the upper rapids only from 8ft. to 16ft. A canal, 165ft. wide at bottom, leads to the power-house containing 20 turbine-chambers. There are 20 turbines, each of 840 b.h.p. The present minimum water power is equivalent to 13,800 i.h.p., while the maximum is more than 15,000 i.h.p. The works have the option of further power to the extent of some 7,000 h.p. In this case they would utilse the fall between the present station and the bridge over the Rhine.

The quantity of water which can be taken through the works amount to some 12,400 cubic feet per second. The turbines are of Francis's reaction type, with two sets of driving vanes and guides. Their speed is 55 revolutions per minute, and they are coupled direct to the electric

Digitized by Google

generators. The lubrication of the turbines is effected under pressure. When working at normal load they have a commercial efficiency of 75 per cent. As the head of water varies so much, the turbines have been designed to accommodate a varying quantity of water, so as to give constant power. The water passed by each turbine thus varies from 600 to 870 cubic feet per second. The type of electric generator used can be seen from the dimensioned sketches (Figs. 2 and 3). The dimensions are given in millimetres. These machines give three-phase current to the network. The design is so arranged that neither of the copper circuits revolves. The armature coils are wound on a laminated iron core, which in turn is fixed to a cast-iron base. As will be seen from the illustration, the magnetising coil for exciting the field is also fixed to a recess in this cast-iron base, so that no collecting rings are required. The revolving part consists merely of laminated blocks of iron inserted in a carrier of the same metal. The apparent output of each phase is 63 amperes at 3,800 volts, or 720 kilowatts in all. Owing to an 80 per cent. power factor, the author states that the true output is 580 kilowatts. The excitation is provided by three rotary transformers each of 150 h.p., which transform the three-phase alternating currents into continuous current for use in the field coils.

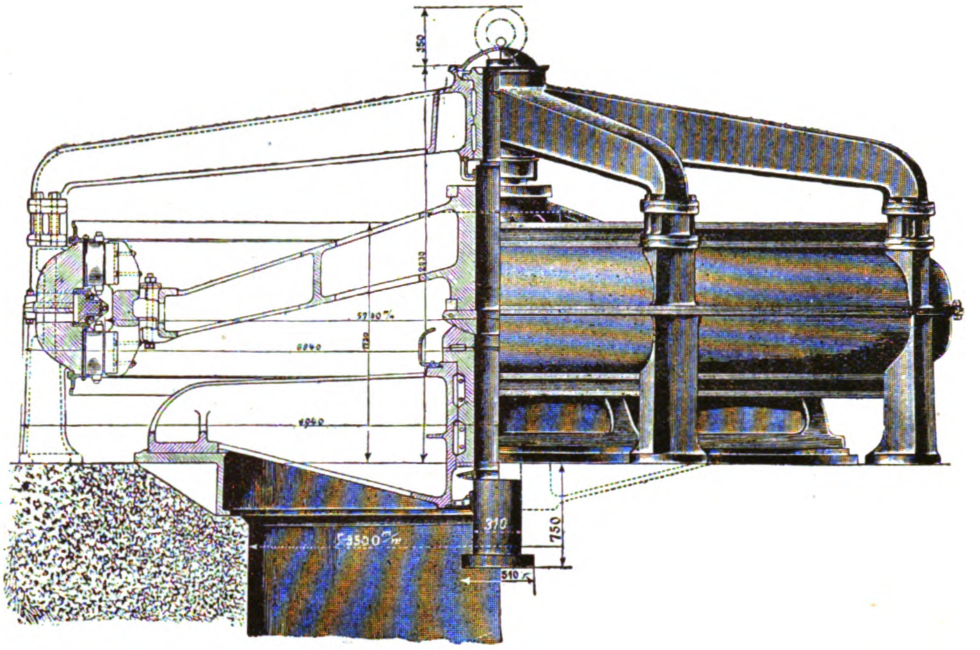

FIG. 2.—Sectional Elevation of the Three-Phase Generator at Rheinfelden.

The works are intended to supply energy anywhere within a radius of 12½ miles from Rheinfelden for industrial and lighting purposes. The area now being provided with mains is shown in Fig. 1. The pressure on the mains will be at first 6,800 volts, and will be supplied directly from the generators. As the demand increases the voltage will be raised to 16,500 volts to give economy in working, and the construction of the mains is such as to withstand this latter pressure. The increase from 8,500 to 16,500 volts will be obtained by transformers. The distribution will be carried out by two distinct systems of mains. One network will thus be used for power only and one only for lighting purposes. In this way the switching on or off of the motors will not affect the lamps, and a larger drop of pressure can also be allowed in the motors' network. The load for supplying the lights will be taken by four of the generators, while 14 will be required to supply the power network. It is estimated that at least half of the power thus delivered will be used for chemical processes.

The total area of distribution is sub-divided into a number of smaller areas, each with two independent distribution networks—*i.e.*, one for light and one for power. The pressure on these is respectively 120 volts for the light-distributing network, and 500 volts for power distribution. The four generators for light can simultaneously feed 35,000 16-c.p. lamps.

The mains used are of bare copper, supported on insulators on poles. The poles keep the wires some 36ft. above the ground at the point of support, and are spaced about 44 yards apart. The same poles carry also the pilot wires and the telephone service. Every 550 yards a lightning arrester is fixed. The current density on which the primary network is calculated is that of 580 amperes per square inch section. The total losses in the lighting circuit are then found to be such that 72 per cent. of the power on the turbine shaft is delivered to the lamps. On the motor circuits a larger loss is allowed, and the total efficiency of distribution falls to 68 per cent. The charges for energy supplied will be low—viz., maximum for light 4·8d. per kilowatt-hour. A sliding scale of discounts wil be allowed, which will reduce the price to regular consumers, the maximum discount being 80 per cent.

The price per kilowatt-hour for industrial purposes will be only 1·9d., but the first cost for installing will be charged, which will vary from £2. 10s. to £8, according to the size of the installation.

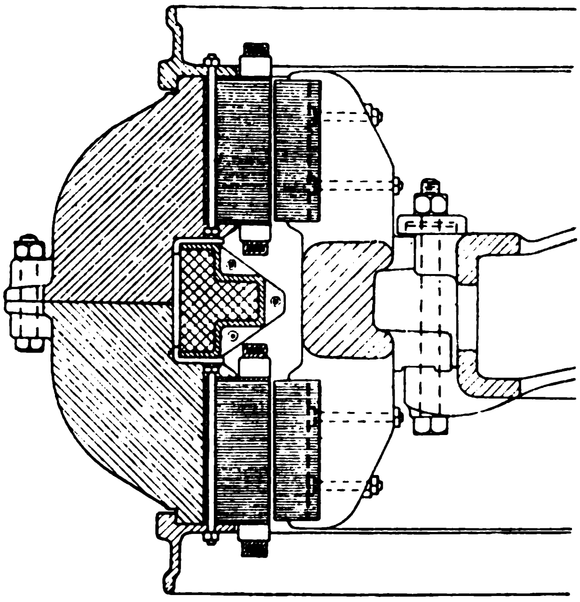

FIG. 3.—Large Scale Section of the Armature Field Magnet.

The rates for motive power will thus compete most successfully with the supply by small steam plants or even with large power. Mr. Rathenau gives the following comparisons for motors working 3,000 hours per year:

Power of motor. Horse-power.	Annual cost by— Steam-engines in the district.	Electricity at above rates.
5	£150	£40
100	1,300	855

It is anticipated that these works will be of great benefit to the district by assisting the industries already established, by encouraging the starting of new factories, etc. The work is being carried out under the able supervision of Prof. K. Zschokke, the consulting enginer being Prof. Intze. The latter gentleman estimates that the first cost will be about £15 for every brake horse-power on the shafts of the turbine. The electric contracts are being carried out by the Allgemeine Elektricitäts-Gesellschafts.

(To be continued.)

THE PRINCIPLES OF ALTERNATE-CURRENT WORKING.*

BY ALFRED HAY, B.Sc.(EDIN.), A.I.E.E.

(Continued from page 18.)

23. After the brief exposition given above of the mathematical principles which we shall have to make use of, we may proceed to consider the fundamental physical facts on which the theory of alternating currents is based.

If the number of magnetic lines passing through any circuit is varied, an E.M.F. is induced in that circuit, which is measured, at any instant, by the rate of change in the number of lines at that instant. This is the principle underlying the construction of all kinds of dynamo-electric machines, and was discovered by Faraday as far back as 1831. The student is supposed to be already familiar with this principle, but it may not be out of place to direct his attention to some special points which will prove useful later on.

Lines of magnetic induction may be made to pass through a circuit either by placing it in a suitable position in the neighbourhood of a magnetised body (or conductor conveying a current) or by passing a current through the circuit. Changes in the number of lines which thread themselves through the circuit may be produced by (*a*) moving the circuit in the field in which it is placed; (*b*) moving the body producing the field; (*c*) altering the current which flows round the circuit; (*d*) distorting the shape of the circuit. The first two methods are made use of in the construction of dynamos and alternators, the third in the construction of transformers and various types of alternate-current motors.

The E.M.F. induced in the circuit lasts only so long as the number of magnetic lines passing through it is varying, and ceases as soon as that number becomes constant (when the rate of change, which determines the E.M.F., is zero).

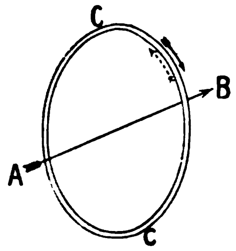

FIG. 14.

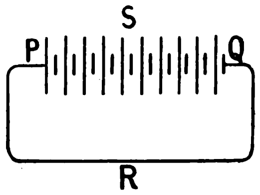

FIG. 15.

24. The *direction* of the induced E.M.F. is such that it always *opposes* the changes producing it. This principle is known as *Lenz's law.* Thus, let the vector A B in Fig. 14 indicate the magnetic field, and let C C_1 represent the circuit. If the length of A B is *diminished* the induced E.M.F. will have the direction indicated by the full-line arrow, and the current due to this E.M.F. would tend to *increase* the length of A B. On the other hand, if we suppose that A B is *lengthened*, the E.M.F. will have the direction shown by the dotted arrow, and the corresponding current would tend to *shorten* A B.

Let us next suppose that the line A B gives the direction of the field due to a current flowing in C C_1. The direction of this current will be that of the full-line arrow. If the current is diminished, the E.M.F. induced during the time that the current is diminishing will have the direction shown by the full-line arrow—*i.e.*, the induced E.M.F. will tend to increase the current; if, on the other hand, the current be made to increase, the induced E.M.F. (dotted arrow) will tend to reduce the current. In either case, therefore, *the induced E.M.F. tends to oppose the changes which give rise to it.*

25. The ratio of the E.M.F. to the current in a given circuit maintained at a constant temperature is defined as the resistance of that circuit. Ohm's law asserts that this ratio is a *constant quantity which is independent of the current.* Hence, Ohm's law may be written in the form

$$i = \frac{E}{r} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (17)$$

where i stands for the current, E for the E.M.F., and r for a certain *constant* which we agree to call the resistance of the circuit.

In applying Ohm's law to any circuit it must be remembered that E in the above equation denotes the total resultant E.M.F. in the circuit; or, if we are dealing with a portion of the circuit merely, E stands for the difference of potential across that portion, plus any E.M.F.'s which may be included in that portion. In many cases there may be more than one E.M.F. in a circuit, and in all such cases it is the *algebraical sum* of the various E.M.F.'s which must be used when applying equation (17). In order to impress this fact on the student's mind, we shall consider a few simple examples.

Let a battery of E.M.F. E, and resistance b, be connected up in simple circuit (Fig. 15) with an external resistance r. Since the E.M.F. of the battery is the only E.M.F. in the circuit, we at once obtain the current i from the formula $i = \frac{E}{b+r}$. Again, P and Q being the positive and negative terminals of the battery, since P is at a higher potential than Q, a current will tend to flow from P to Q. In the branch P R Q we have no E.M.F., so that if V denote the potential difference between P and Q, the current flowing from P to Q along P R Q is equal to $\frac{V}{r}$. In the branch P S Q, however, we have the opposing E.M.F. of the battery, so that the current which passes from P to Q along P S Q is $\frac{V-E}{b}$. Now, since E>V, it follows that V − E will be negative—*i.e.*, the current will, as we know, pass from Q to P, and not from P to Q, although P is at a higher potential than Q.

To take another example, let us suppose that a dynamo is charging a set of secondary cells. Let V be the potential difference at the terminals of the cells, E their E.M.F., and b their resistance. The current going into the cells is $i = \frac{V-E}{b}$. So long as V>E, V − E is positive, and the cells are being charged; but if (owing, say, to a lowering of the speed of the dynamo) V becomes less than E, V − E will be negative, and the cells are discharging through the dynamo, driving it as a motor.

The above examples will suffice to show that in applying Ohm's law to any circuit, or part of a circuit, a certain amount of discretion must be used. The whole of the E.M.F.'s present in the circuit, or that part of it which is being considered, must be taken into account.

26. As a final example, we shall consider the case of a circuit *in which the current is varying.* As has been already explained in Art. 24, the variations of the current call into play E.M.F.'s of induction, and these have to be taken into account in determining the current. It is useful to draw a distinction between the E.M.F. which is the primary cause of the current, and the induced E.M.F.'s which merely make their appearance when the current is undergoing variations. The first is generally termed the *impressed* E.M.F. At any instant, the following relation holds:

$$\text{current} = \frac{\text{impressed E.M.F.} + \text{induced E.M.F.}}{\text{resistance.}} \quad (18)$$

It is the *algebraical* sum of the E.M.F.'s that is understood in the numerator of the fraction on the right-hand side of (18). The induced E.M.F. may be either of the

* Based on a series of evening lectures delivered at the University College, Liverpool.

Digitized by Google

same sign as the impressed E.M.F., or of opposite sign. The relation expressed by (18) is an extremely important one, and we shall frequently have occasion to use it.

27. It is necessary to say a few words with regard to the *power* in a circuit containing several E.M.F.'s. To begin with, suppose we have a circuit of resistance r, in which there is only one E.M.F., say E. The current is $i = \frac{E}{r}$. The rate of expenditure of energy is $E\,i$, or $i^2\,r$. The latter represents the rate at which heat is being produced in the circuit, and in this case the whole of the energy which is supplied by the source of E.M.F. is being converted into *heat*. Next, suppose the circuit to contain an opposing E.M.F., or counter E.M.F., of amount e. The current will now be $i_1 = \frac{E - e}{r}$, whence $E = i_1\,r + e$. The power is $E\,i_1 = i_1^2\,r + e\,i_1$. The first term, $i_1^2\,r$, represents, as before, the rate at which dissipation of energy takes place by heating of the circuit; the second term, $e\,i_1$, represents the rate at which energy is being absorbed by the source of counter E.M.F. This energy may either be *stored up* (as in the case of secondary cells), or it may be converted into any other form of energy which undergoes immediate further transformations (as in the case of an electromotor). The whole of the power in the circuit may therefore be regarded as made up of two parts: one part going towards producing *heat* in the circuit, the other towards the transformation of the electrical energy into forms *other than that of heat*. When the current in a circuit is increasing, the counter E.M.F. induced in the circuit causes *storage of energy*, the form which the energy takes being that of a magnetic field. The magnetic field due to a current, in fact, represents so much potential energy, and we shall see presently how this energy may be determined.

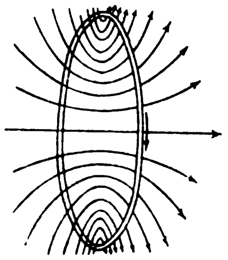

FIG. 16.

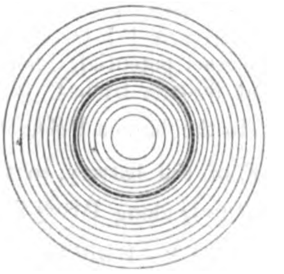

FIG. 17.

Considering next the most general case, in which we have a number of E.M.F.'s in a circuit of resistance r, let us suppose that the E.M.F.'s whose direction is the same as that of the current, i, are denoted by E_1, E_2, E_3 . . . , and the E.M.F.'s which are opposed to the current by e_1, e_2, e_3, etc. The E.M.F.'s E_1, E_2, E_3 etc., act as *sources* of energy; the E.M.F.'s e_1, e_2, e_3, act as absorbers or *sinks* of energy. The *current* in the circuit may be regarded as transferring energy from the sources to the sinks. But this transference cannot be accomplished without a certain amount of the energy being dissipated in the form of heat, the rate of dissipation being given by $i^2\,r$. We thus have the equation:

$$\underbrace{(E_1 + E_2 + E_3 + \ldots)\,i}_{\text{Total rate of production of energy}} = \underbrace{(e_1 + e_2 + e_3 + \ldots)\,i}_{\text{rate of absorption}} + \underbrace{i^2\,r}_{\text{rate of dissipation.}}$$

28. Consider a simple circuit conveying a current. A certain number of magnetic lines will thread themselves through the circuit, as shown in Fig. 16. It must be understood that the lines which we are considering are merely *those due to the current* in the circuit, and do not include any lines which may be due to the presence of magnets or other circuits conveying currents. We also suppose that the medium surrounding the circuit is air. We shall call the total number of magnetic lines (due to the current) passing through the circuit the *magnetic flux* through the circuit. This magnetic flux may be regarded as made up of two parts—viz., the lines which pass entirely outside the conductor forming the circuit, and the lines in the substance of the conductor. In Fig. 17 let the thick-line circle represent the section of the wire forming the circuit. The thin-line circles are supposed to represent the magnetic lines *due to the current*.* At the centre of the circle* the magnetic force is zero. As we proceed from the centre outwards the magnetic force gradually *increases*, reaching a maximum just at the boundary of the conductor; on receding from the boundary of the wire we find that the magnetic force *decreases*. In the case of many circuits the part of the magnetic flux which is confined to the substance of the conductor is but an insignificant portion of the total flux, but in other cases (more particularly in the case of iron wires conveying currents) it may be considerable.

29. Since we have supposed the circuit to be surrounded by air, it follows that the magnetic flux through it will be directly proportional to the current. Hence, if F stand for the total magnetic flux due to a current i, we may write

$$F = L\,i \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (19)$$

where L is a constant which is independent of i. The constant L is termed the *coefficient of self-induction*, or *inductance*, of the circuit. Since F becomes equal to L when $i = 1$, we may define the *inductance of a circuit* as *the magnetic flux through it due to unit current.*

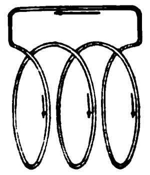

FIG. 18.

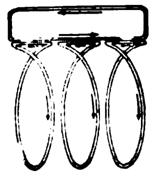

FIG. 19.

We have next to explain the meaning of the term "inductance" when applied to a complex circuit such as a coil of wire. The circuit represented in Fig. 18 is supposed to be made up of three loops In order to determine the magnetic flux due to unit current, we may imagine the complex circuit split up, as in Fig. 19, into a number of simpler circuits. The sum of the magnetic fluxes through the various simple circuits into which the complex circuit has been broken up gives us the total magnetic flux due to unit current, and this we define to be the *inductance* of the complex circuit.

30. If we imagine a coil the diameter of which is large compared with the dimensions of its cross-section, we can easily deduce an approximate expression for the inductance of the whole coil in terms of the inductance of a single turn. For in the case of such a coil we may roughly assume that the magnetic flux through each turn will be the same. Let l stand for the inductance of a single turn of the coil, and let there be S turns in the coil. Then, since a unit current through one turn causes l lines to pass through that turn, a unit current through the whole coil—*i.e.*, through S turns—will cause $S\,l$ lines to pass through *each* turn. Hence the total magnetic flux through the coil when conveying unit current—*i.e.*, its *inductance*—will be $S \times S\,l = S^2\,l$. We thus arrive at the result that the inductance of a coil varies approximately as the *square of the number of turns* in it

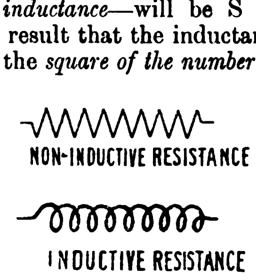

FIG. 20.

31. In the case of some circuits, such as a wire which is doubled back upon itself, the inductance is extremely small. Such circuits are usually called *non-inductive* circuits. It is impossible to obtain a circuit which is absolutely non-inductive, but the term is applied to circuits whose inductance may, for all practical purposes, be left out of account. By an *inductive* circuit we mean one whose inductance is appreciable. It is convenient to have special symbols for denoting non-inductive and inductive resist-

* This is only an approximation. It would be strictly correct for an infinitely long wire at a distance from all other conductors conveying currents.

Digitized by Google

ances, the symbols in general use being those shown in Fig. 20.

A common form of non-inductive resistance consists of a wire doubled on itself. The magnetic field due to such an arrangement is represented in Fig. 21. The points of zero magnetic force O and O_1 are not at the centres of the two conductors (the outlines of whose sections are indicated by the thick-line circles), but are displaced outwards. Such an arrangement produces an external field, which, however, becomes extremely feeble as the distance from the conductors increases.

A more perfect arrangement is obtained by making one of the conductors a hollow cylinder which completely encloses the other. The lines of magnetic induction in this case consist of concentric circles, as shown in Fig. 22, and there is absolutely no field outside the conductors, the lines being entirely confined to the substance of the conductors (and the thin layer of insulation between them). Figs. 21 and 22 are both drawn roughly to scale, the conductors being supposed to convey the *same* current in each case. By counting the number of lines in the two cases, the student will see that the arrangement shown in Fig. 21 gives rise to about three times as many lines as that shown in Fig. 22.

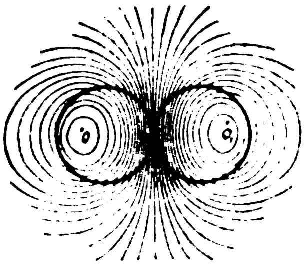

Fig. 21.

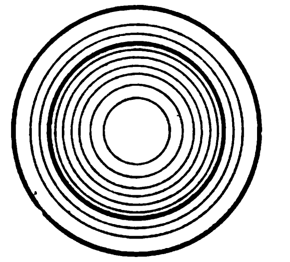

Fig. 22.

For all practical purposes, two conductors (of non-magnetic material) laid side by side—the one conveying the outgoing current and the other the return—may be regarded as forming a non-inductive arrangement. In many cases, in fact, a conductor forming a *narrow* loop (such as the filament of an incandescent lamp) may be considered as a non-inductive circuit.

32. Let us suppose that a steady E.M.F. is suddenly applied to an inductive circuit of resistance r. The current will not *suddenly* rise to its steady value, $\frac{E}{r}$, but will take an appreciable (though in most cases very short) time to do so. This is due to the fact, already explained, that as soon as the current begins to rise a varying magnetic flux is introduced in the circuit, and this varying flux induces an E.M.F. which opposes the current. While the current is growing, energy is being absorbed by the circuit in other ways than that of heat (Art. 27). What becomes of this energy? The answer is, that it becomes stored up in the form of a magnetic field surrounding the circuit. We shall now show how this energy may be calculated if the inductance L of the circuit is known.

Suppose N magnetic lines to be introduced during t seconds into a circuit in which a steady current of i C.G.S. units is maintained. The counter E.M.F. induced by the insertion of the lines is (Art. 23) $\frac{N}{t}$; hence the rate at which work is being done against the induced E.M.F. is (Art. 27) $\frac{N}{t} \cdot i$. The total amount of work done will therefore be $\frac{N}{t} \times i \times t = N\,i$ ergs. We thus have the following important result:

In increasing the magnetic flux through a circuit conveying a current i by N lines N i ergs of work are done.

From this we see that in order to build up the magnetic field of any circuit conveying a current, a definite amount of energy must be supplied to the circuit. We can easily determine this amount by the following method.

Taking the most general case of a circuit, in which the magnetic flux is *not* proportional to the current—*i.e.*, a circuit containing cores of magnetic material—let us suppose that the curve O B F D G (Fig. 23) gives the relation between the current in the circuit and the corresponding magnetic flux through the circuit. Let us suppose that at a certain instant the current has the value A B, and the corresponding flux the value O A. Let the current be made to increase by a *very small* amount, so as to assume the value C D; the magnetic flux will increase by the small amount A C. Since the length B D of the curve is supposed to be very small, we may regard it as a short straight line. The *mean* value of the current between A B and C D will then be given by E F, where E is such that A E = E C. Instead of supposing that the current steadily increases from A B to C D, we may assume that it has the constant mean value E F while the flux increases by A C. The work done in increasing the flux will then be, by the proposition just proved, A C × E F = area of A B D C, so that in increasing the current from A B to C D, and the flux from O A to O C, an amount of work is done which is represented by the area A B D C. The same result holds for every small increase of the current. Hence, the energy communicated to the magnetic field when the current rises from its zero value to the value H G is represented by the area O B G H.

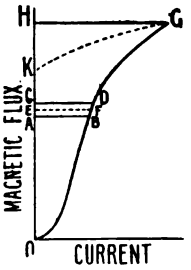

Fig. 23.

In the case of a circuit whose permeability is constant, the flux is simply proportional to the current, and the relation between these two quantities will be represented by a straight line, as shown in Fig. 24. Let us suppose that the inductance of the circuit is L. In starting a current i = A B in the circuit, we store up an amount of energy in the magnetic field which is equal to the area of the triangle O B A—*i.e.*, to $\frac{1}{2}$ L i^2 (since A B = i, and O A = L i). Hence,

The energy stored up in the magnetic field of a circuit of inductance L conveying a current i is $\frac{1}{2}$ L i^2 ergs, L and i being measured in C.G.S. units.

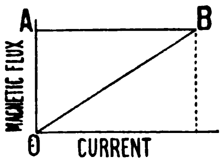

Fig. 24.

When the current is arrested by breaking the circuit, the potential energy of the magnetic field makes its appearance in the form of a spark. In the case of a circuit whose permeability is constant, the *whole* of the energy is returned at the instant of breaking the circuit, since all the magnetic lines which were produced by the current disappear on breaking the circuit. But when the magnetic flux passes through a substance exhibiting *hysteresis* part only of the energy is recoverable. Thus, if in Fig. 23 the dotted curve G K represent the descending branch of the hysteresis curve, the energy which is returned by the circuit when the current is arrested is represented by the area G K H. The area O B G K represents the energy dissipated *in the magnetic substance* by heating of the latter. If we suppose the magnetic substance carried through a complete cycle, we see that *the energy dissipated is represented by the area of the hysteresis loop.* The abscissæ of the loop, it must be noted, represent *current*, and the ordinates magnetic flux.

Since the energy stored up in a circuit of given inductance is proportional to the *square* of the current, it will be

Digitized by Google

readily seen why the destructive effect of a spark increases very rapidly with the current. Thus, by increasing the current tenfold, the destructive effect of the spark is increased a hundredfold.

The *practical* unit of inductance is termed the *henry*, and it is equal to 10^9 C.G.S. units. In order, therefore, to determine the magnetic flux in C.G.S. lines through a circuit of inductance L *henries* conveying a current of *i amperes*, we must multiply the product $L\,i$ by 10^8 ($=10^9 \times 10^{-1}$), and in order to determine the energy stored up in *ergs*, the product $\frac{1}{2}\,L\,i^2$ must be multiplied by 10^7.

In most cases occurring in practice the inductance of a circuit is expressed by a small fraction of a henry.

(To be continued.)

RAILWAY BLOCK SIGNALLING.

BY J. PIGG.

(Continued from page 39.)

Instruments of the second division are subject to a class of disturbance which does not affect those of the first division. In consequence of the generally lighter construction and greater sensitiveness of the former, they are affected to a much greater degree by the presence of earth currents or the occurrence of "magnetic storms." Whilst the latter class of disturbance are of rare occurrence and never for prolonged periods, the former are nearly always present, and the selection of an earthing point which will allow of the block indicators keeping their normal position exactly is frequently a puzzle of no mean order. Earths which are made within a few yards of each other often give quite different results, and combinations of different earths will often give results which cannot be obtained from any of them separately. Moreover, there is no certainty that uniform results will be obtained from any earth or combination of earths which on being first connected are found to work satisfactorily; indeed, it is no uncommon experience for them to change before the man leaves the place.

At places where the earth connection has to be made in rocky or sandy soils, the resistance to earth is sometimes considerable, and "contact" between the different instruments ensues. It is not always possible to obviate this defect by utilising the rails as the return, more especially during dry weather and in places where junctions intervene. The remedy for these defects is obvious, and consists in diminishing the sensitiveness of the block indicators, and since "the movements of the block instruments and bells must be made slowly and distinctly," there is no necessity for so great a degree of sensitiveness in instruments as block working.

The relative cost for construction and maintenance of the three-wire continuous-current and the one-wire transient-current systems is a subject upon which, as has already been stated, considerable emphasis has at different times been laid. Where the instruments for use with one line wire are not overweighted with patentees' royalties there can be no doubt of the smaller cost for construction, and, other things being equal, for maintenance also. But it should not be forgotten that a complete block section includes, besides the electrical equipment, the lines themselves, the necessary buildings, and the mechanical signals and points, with their interlocking mechanism, and that of these items the electrical is probably the least expensive. Hence, the *difference* in the cost between a three-wire and a one-wire system is likely to be an almost inappreciable fraction of the *total* cost of the section, and this is rendered still more apparent when it is considered that the most expensive item of the electrical equipment—the construction of the pole line—is invariably used for other purposes than block working proper.

Hence, whilst it may be said that block circuits using one line wire and transient currents may be somewhat cheaper to maintain than circuits requiring three wires and continuous currents, yet the difference is small, and its importance is discounted by the greater variety of signals that may be used on the latter without an unnecessarily intricate code; the additional indication provided between the acceptance of the "Is line clear" signal and the "Train entering section" signal; the greater certainty of the indicators being in accordance with the conditions under which the line is worked when a defect exists in the block apparatus; and the self-testing character of the apparatus used.

The simplest case of block working is shown in the diagram (Fig. 9), in which the cabin, A, is an intermediate point between two others of more importance. Such a

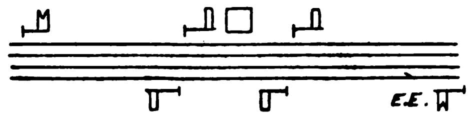

Fig. 9.

cabin is a mere passing place, and is only of use for shortening what would otherwise be too long a section for the amount of traffic passing, and is generally to be found in connection with some road crossing, or at a point near distributing sidings, or for stopping trains at a conveniently situated point to a junction where two or more lines converge. The next case in order of importance is shown by Fig. 10, where a relief siding is provided into which a train may be shunted in order to allow more important trains to pass. Fig. 11 shows a junction where three lines converge, and Fig. 12 shows a particular case where the lines connecting junction points form a triangle.

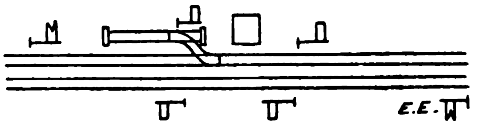

Fig. 10.

The diagrammatic representation of the wires and instruments for such cases as Figs. 9 and 11 are shown in Figs. 13 and 14 respectively.

The case represented by Fig. 12 introduces the 400 yards rule by which signalmen, in cases where the distance

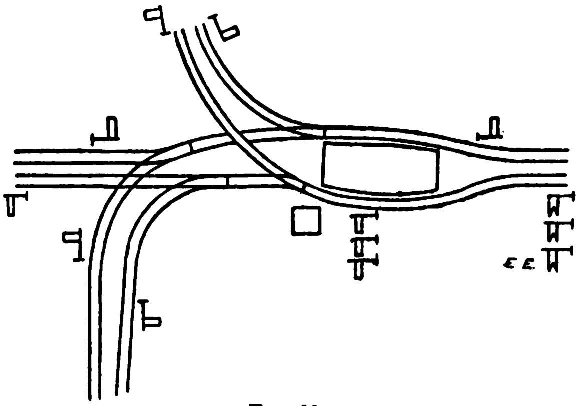

Fig. 11.

between successive cabins is 400 yards or less, must, before accepting the "Is line clear" signal from the rear cabin, obtain its acceptance from the advance cabin.

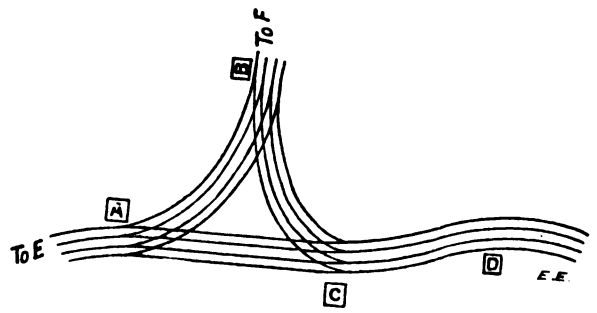

Fig. 12.

The arrangement of apparatus for the case represented by Fig. 12 is given by Fig. 15, and is peculiar for the

Digitized by Google

means taken to obviate accidents likely to arise from local conditions. In general, however, the difference between an ordinary section and one under the 400 yards rule is in

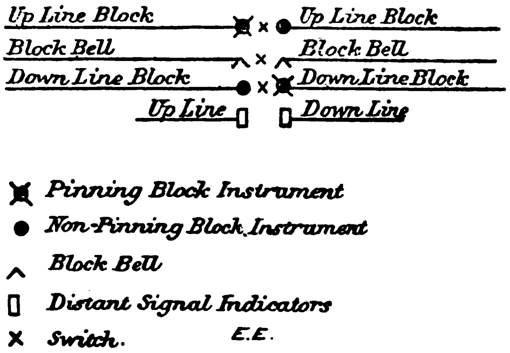

Fig. 13.

the rule for the acceptance of the "Is line clear" signal only, and does not involve any difference in the apparatus.

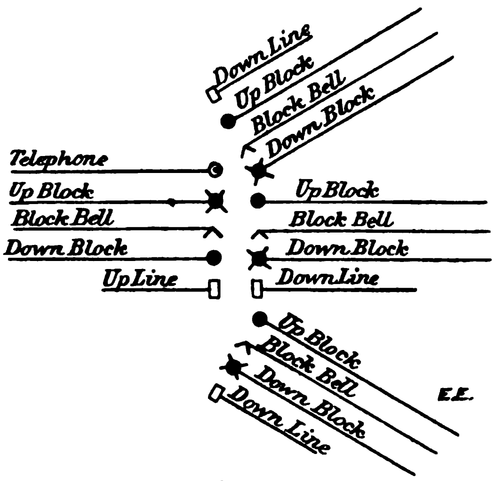

Fig. 14.

In the case under consideration the "down" line between E and D is on a falling gradient, and passes through a long tunnel between E and A. The block cabins, A, B, C, and D, are each within 400 yards of the next, and the acceptance of an "Is line clear" signal by A for a train passing to D is conditional upon its acceptance by both C and D, the latter being offered the "Is line clear" signal by C before accepting it from A.

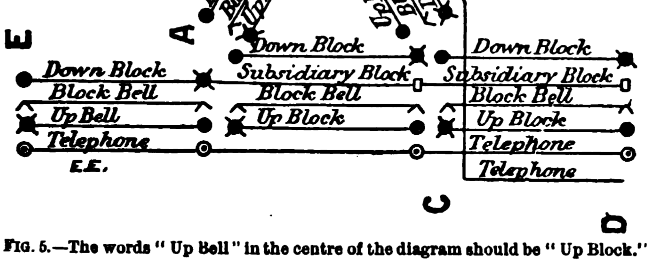

Fig. 5.—The words "Up Bell" in the centre of the diagram should be "Up Block."

Hence, before a train can leave E for D the line must be quite clear to the latter point, or through three sections, and in order that A may not accept a train from E without the knowledge of C and D, the "down" line instrument circuit between E and A is continued through indicators fixed in C and D, which reproduce at those places the indications of A's "down" line instrument at any time. Hence there are two independent checks on A's actions in accepting an "Is line clear" signal, and the indications are also of considerable value to C and D for the regulation of traffic to and from the section C B.

CONVERSAZIONE OF THE INSTITUTION OF CIVIL ENGINEERS.

The Institution of Civil Engineers have this year again taken up their old practice of holding conversaziones to which ladies are admitted. The number of members wishing to view the new buildings and to be received by the president of the institution was so large that two nights had to be taken to prevent undue crowding. The two evenings selected were July 15 and 16, and the night to which any individual member was invited to attend was determined by ballot. We were privileged to be present at the first evening's entertainment. The whole of the new buildings of the institution were most extensively decorated for the occasion with muslin draperies, flowers, and palms. We noticed a large number of celebrities present, of whom, of course, the electrical engineers formed a minor part, but such men as Lord Kelvin, Prof. Ayrton, Mr. W. H. Preece, Mr. Alexander Siemens, Prof. Kennedy, and Dr. John Hopkinson represented this branch of the profession. The entertainments were carried out in the whole of the rooms, the architecture of which were much admired by the guests.

An excellent programme had been arranged for the entertainment of the visitors. Prof. Roberts-Austen, C.B., F.R.S., with the aid of a lantern and an electric furnace gave a demonstration of the utility of electricity in melting certain refractory metals. Mr. Alexander Siemens and Prof. J. Norman Collie gave exhibitions of views illustrating their recent journeys, the former to the River Amazon and the latter through the Himalayas. The Röntgen rays, of course, proved very attractive, and the two rooms where this latest wonder could be seen were always crowded. Mr. Campbell Swinton in one room showed the results he had obtained with the rays, and in the other room Messrs. Siemens gave practical demonstrations with the rays and with vacuum tubes.

Another distinct feature was the exhibition of paintings, many of which had been lent, and many of which are the property of the institution.

There was an interesting display of models and scientific apparatus akin to the profession, and these were inspected with the greatest interest. The Royal Ordnance Factories exhibited specimens of electric welding of steel tyre bands and two sections of the barrels of 4·7in. quick-firing guns, illustrating the difference between the erosion caused by gunpowder and by cordite. The diving helmet shown by Mr. W. A. Gorman, A.M.I.C.E., attacted considerable attention. It was fitted with electric light and loud-speaking telephone. Messrs. Siemens Bros. had several exhibits, among which were a model of electric steering gear, tubular bearings reducing friction to a minimum (especially applicable to tramcars), samples of joints in non-hygroscopic lead-covered cables, and samples of the Amazon Company's sub-fluvial cables, showing river cable, shore end, and underground cable in trenches. Dr. Alex. Muirhead had a syphon-recorder at work with automatic curb transmitter, receiving messages through artificial cable equivalent to 3,000 knots. In the upper part of the staircase well we noticed two of Messrs. Drake and Gorham's "Jandus" arc lamps.

The music was exceedingly enjoyable. The string band of the Royal Artillery played during the evening, and no higher words of praise than the mention of their name can be uttered, unless, perhaps, one notes the fact that Cavaliere L. Zavertal, R.A., conducted. The vocal music was under the direction of Mr. William Coates, and consisted of madrigals, glees, and part-songs. The artistes were Masters Every, Cooper, Thomas, and Young, and Messrs. George May, Ernest Taylor, Harper Kearton, Charles Edwards, Wm. Coates, R. De Lacy, and George Stubbs, and their singing charmed everybody.

Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 11d.	9s. 9d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XVI. of new series of "THE ELECTRICAL ENGINEER" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

THREE-WIRE PATENT.

On Wednesday the Judicial Committee of the Privy Council decided "not to report to her Majesty in the way which was necessary for a prolongation of the patent." The patent referred to is that of Dr. Hopkinson's, best known as the "three-wire patent." The reasons for this adverse decision are to be given at a later date, but we presume our readers do not care much about the reasons so long as they know the result. It greatly surprised us to learn that many people feared a prolongation of this patent, as in our opinion there never was any valid reason put forward in support of that course. The main facts are extremely simple when the legal, sentimental, and commercial addenda are stripped from them. Dr. Hopkinson patented a system of distribution which has been largely used. He sold his interest in this patent to a company, and so it must be at once and finally accepted that he was in his own estimation adequately paid for his work. The company that bought the patent, finding it valuable, naturally desired a prolongation. The directors would not be human if they did not wish to continue a certain source of income as long as possible. In our opinion, however, neither legal forms, sentimentality, nor morality justify the extension of a patent when the inventor has been pecuniarily satisfied for his work. The company did not buy this patent with the idea of recouping itself after the lapse of the patent, but with the idea that it would be amply repaid before such lapse. Of course it was worth while going for an extension, inasmuch as no one is absolutely certain what view judges will take; and if on the off-chance that view prove favourable to the company, a stake would be won that was certainly worth trying for. Surely, however, the ordinary conditions of patent law are satisfied with the one point, "the inventor is satisfied." It ought not to consider the wishes of a speculative company desirous of exploiting something to its own advantage and not to the advantage of the inventor. If Dr. Hopkinson had never sold his interest, and had depended upon the return from royalties during the life of the patent, and these royalties had been unsatisfactory through the necessity in the first place to get a public who understand the value of the patent, and in the second, to the lack of enterprise by that public in using the patent, the question would have had to be approached in a different manner. In this particular case the inventor has been satisfied, and though the company naturally wants more, it has not done badly. There is another way in looking at these questions of patent rights and satisfactory remuneration, assuming the inventor to be the only party interested. Is his satisfactory remuneration to be calculated from what he would have been satisfied with in the early days of his patent — that is, should he put his value upon the patent when he takes out the patent, or should it be calculated from the consideration of the question towards the end of the period of the life of the patent? An inventor should be treated more than justly: he should be treated generously. It is largely his work that renders the progress of the world possible, and niggardliness to such men

Digitized by Google

should be avoided. Ofttimes he is years before the world is ready for him, and then meets with the cold shoulder. In the particular case under notice the industrial world has recognised for a number of years the value of the patent, and the inventor was at any stage of its life capable of looking after his own interests. The decision, then, may be looked upon as unavoidable, and probably when the reasons of the judges are known, they will be found to be merely an amplification of the view that, the inventor himself being satisfactorily remunerated, any exploiters must take their own risk.

ENGLISH APATHY.

In the Board of Trade *Journal* for the present month will be found an extract from our Consul at Bilbao. It contends that we are losing business because of our lack of enterprise. We take the most effective way we possess to bring these remarks before our readers. Just as we have recently sent a representative to Germany, we hope next month to send to Bilbao, after which no doubt a better opinion can be formed on this matter. The following is the extract referred to: "Her Majesty's Consul at Bilbao says that electricity is daily more used in that district. The light is used in streets, in villages, on the river, and in many houses; an electric tramway has been laid down from Bilbao to Santurce, and another one is under construction down the right bank of the river. But the names of British firms are not noticeable on any of the apparatus. None of it is made in Spain: all has to be imported, so that there is a field for competition. The only thing is that Germans have got the start. It might be well worth the while of British firms to try whether they cannot secure part of the business. Even if they cannot compete in price, it is to be hoped that they can excel in quality, and it may be observed that as regards price the Germans are handicapped by the payment of a heavier duty. If these remarks meet the eye of electrical plant manufacturers, they will—that is, the more enterprising ones, unless they are different from other manufacturers—write to ask for lists of firms to which they may send their price-lists, which are made out in English. The answer would be that a list of firms will be found in the 'Libro de Bilbao,' published by Larrañaga y Lejarcegui, Calle de Ledesma, No. 22, Bilbao, who will send it post free for 3s., but that it is far the best plan to send a traveller. The fact is, that a traveller is almost necessary when it is desired to supersede an article already in possession, but unfortunately the use of travellers never seems to commend itself to British firms."

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

CENTRAL-STATION STAFFS.

Sir,—During the recent meeting in London of the Electrical Association a paper was read on the organisation of the engine-room staff. Now, the smooth working of a station depends on the order and management. It is only right and proper that the chief engineer should have absolute control of all his staff, that he should have the authority to appoint or discharge any man in the station, no matter whohe may be. It is a grave error for committees to make appointments. If a committee trust their engineer, why not let him choose his own men? Surely he is the best judge in these matters, seeing he is responsible for the working of the station. During the discussion following this paper a gentleman mentioned a case where the chief engineer was annoyed by his assistant, who, being appointed by the influence of a committee member, thought he could snap his fingers at his chief. This is not right; let the engineer have absolute power. In every station there should be two departments: mechanical and electrical. The engineer should have charge of the engine-room and stokehole, the electrician the charge of dynamos and switchboard, both men being under the charge of the chief engineer. In stations, however, the assistant engineer (who in nine cases out of ten knows as much about engines as the man in the moon) is looked up to with reverence, and "Mister" prefixed his name, while the engineer proper is contemptuously termed an "engine-driver," and is plain Smith or Jones, etc. Red-tape "won't wash," though—the colour comes out. Take, for instance, a lad. He serves his time with an electrician. When out of his time he applies for an assistant's berth in a central station. He obtains it. He has charge of the whole of valuable machinery, mechanical and electrical. He might have a fair knowledge of electricity, but what on earth does he know about engines and boilers? The engine-driver must stand by and be told how to do his work by a boy of 21, who perhaps had charge of engines before the other was breeched! It stands to reason that a young man cannot be efficient in both trades. Of course, an older man having had experience both ways is competent, but the majority are youngsters. Engines are as important as dynamos.

These appointments should be made according to Board of Trade rules, which should compel the candidate to produce certificates of competency in both branches. As a member remarked during the late meeting, central stations were in a good many cases training schools at the expense of the corporation.

Corporations make a grand mistake in appointing men who are electricians only, but no doubt they are ignorant of the risk they run. As long as the engines and boilers work all right the assistant gets the praise; but in the case of mishap, who is blamed? Not the assistant. I think it is time now that attention was called to this.

Trusting that I have not monopolised too much of your valuable space, and thanking you in anticipation—Yours, etc., Fair Play.

CHOKING COILS AND ARC LAMPS.

Sir,—My attention has been called to a criticism on my interview with Mr. C. P. Feldmann in a contemporary of the *Electrical Engineer*. The editorial comment is to the effect that when Mr. Feldmann says "voltage," he means current. The description is that of a system of arc lamps with choking coils in series, and the sentence in question is as follows: "If from any cause the lamp goes out the choking coil immediately takes up the whole current of the circuit, and at the same time keeps the voltage constant." Mr. Feldmann kindly added a note to explain how a choking coil when properly designed could do this. I regret that the editor of the contemporary in question has not enough technical knowledge to understand this simple deduction from Ohm's law, and should throw doubt on Mr. Feldmann's statements. Under the circumstances it would be better if he confined his criticism to the language and motives of vestrymen, of which in the first part of the same issue he shows himself to be fully conversant.—Yours, etc.,

Your Special Correspondent.

James Eadie, Limited.—This Company, which has been started with a capital of £500,000, takes power to construct and maintain, among other things, electric works.

THIRD RAIL ON THE NANTASKET BEACH ROAD.*

The second step toward the operation of its main lines by electricity was made June 26 by the New York, New Haven, and Hartford Railroad Company in the extension of the electrical equipment of the Nantasket Beach line as far as East Weymouth, 3½ miles along the main line of the South Shore branch of the Plymouth division, of which Mr. J. C. Sanborn is superintendent.

In determining upon this extension the overhead trolley system in use on the Nantasket Beach branch was abandoned and the third-rail method of contact chosen as the most readily adaptable to ordinary railroad requirements. While the third-rail system for electric roads is not new, it being in use on the West Side and Lake-street elevated railways in Chicago, the rail being set outside the track, this is the first instance of a third rail being laid upon the permanent way of a trunk steam road, between the rails of the service track.

The current for the third-rail section is brought from power-house No. 1, on the Nantasket line, over two insulated feeders of copper cable laid along the tops of the poles which carry the overhead wires of the Nantasket line. At the Nantasket Junction station the feeders are dropped to the ground, and each is connected to its own third rail.

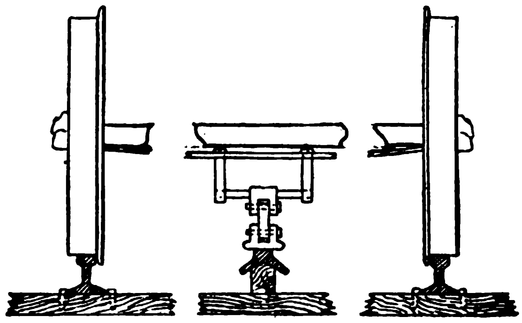

Fig. 1.

The third rail is of peculiar shape, the end view resembling a flattened A (Fig. 1). It is laid midway between the two service rails of each track. Each section of third rail is 30ft. long, and weighs 93lb. to the yard. It is supported by three ash blocks to each section, the blocks being let into the ties. Before use these blocks are boiled in vacuum pans with a tar compound, and thus each pore is filled with insulating and preservative material. The insulation is almost perfect. The continuity of the third-rail circuit is secured by attaching each end of one rail to that of the next by means of two heavy copper bonds. The line between Nantasket Junction and East Weymouth is absolutely distinct electrically from that between the first-named stations and Pemberton. It is fed by its own feeders and is provided with its own automatic safety appliance which, in case of carelessness or accident to the third-rail section, enter into action and cut all current off from it, rendering it nothing more than a peculiarly laid stretch of track.

The electricity is taken from the third rail by two sliding shoes (Fig. 2) hung loosely from the car, one suspended between the axles of each truck immediately under the king-pin by two links, which allow it to slide easily over the top of the third rail and make perfect contact with it all the time. The current is brought to the motors through the controllers and circuit breakers, and returns to the track rails by the wheels. The continuity of the return circuit is secured by using a short, thick bond of copper cable to join together the ends of each pair of track rails, the ends of the bond being fastened into the flange of the rail. The distance between each of the two shoes on the car is 33ft. No third rail is laid at the crossings, the circuit continuing between the broken end by means of lead-covered cables. At the crossings, less than 30ft. wide, one of the shoes is always in contact; at wider ones the inertia of the moving car brings the shoes into contact again before the car can come to rest.

* From the *Electrical Engineer* (New York).

The baggage-cars in use last year, each equipped with four motors, have been abandoned, and the large 16-bench open cars are alone employed as motorcars or locomotives. Sixteen of these cars will be put into service, each equipped with two General Electric "2,000" motors, two series-parallel controllers, two automatic circuit breakers—the safeguards from accident to the rest of the electrical apparatus—and an air-pump and motor for the compressed air for the whistle and brakes. The air-pump combination is automatic in its action. As soon as the pressure in the main air-tank falls below 90lb. to the square inch a small knife switch is closed by a spring and the motor starts. The switch is forced open by the air pressure as soon as that in the tank reaches the normal.

The cars leave Pemberton and run with the trolleys as far as Nantasket Junction. The trolley is then pulled down and hooked, and the shoe strikes the third rail, the passengers being unaware of the change in the method of contact. The regular schedule of the electric trains between Pemberton and East Weymouth has been in force since June 14, but owing to the non-completion of the third-rail section the trains have been hauled from Nantasket Junction to East Weymouth, 3½ miles, by two steam locomotives.

A good idea of the advantage of electricity as a motive power compared with steam may be gathered from the fact that the two locomotives burn each four tons of coal per day, while not more than four tons per day burned in the power-house serves to generate sufficient power to operate the whole seven miles of line between Pemberton and Nantasket Junction by electricity. The construction of the new section has been carried out under the personal supervision of Colonel H. H. Heft.

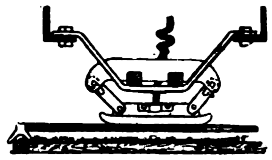

Fig. 2.

During a recent test with the officials of the railroad on board a speed of from 70 to 80 miles an hour was attained. On arrival at East Weymouth the car was switched over, and the return trip was made from East Weymouth to Pemberton in about 11 minutes, the distance being about 10½ miles. Should the operation of this road prove successful, it is probable that the third-rail system will be extended as far as Braintree, a station 10 miles out of Boston, and if the success of the new method under the ordinary conditions of constant travel fulfils all expectations suburban service throughout the country will probably undergo a change.

ALTERNATE-CURRENT TRANSFORMERS.*

BY DR. J. A. FLEMING, F.R.S.

LECTURE I.

The Action of the Transformer.

In the last 10 years the alternate-current transformer has been developed from an experimental instrument into a practical appliance of immense utility. According to recent statistics, there are at present about 50 alternating-current electric supply stations in the United Kingdom, supplying not less than 1,100,000 8-c.p. lamps. This amount of lighting requires the expenditure of 54,000 h.p., or 40,800 kilowatts at full load, and hence there must be transformer capacity in the United Kingdom at the very least equal to 40,000 kilowatts. These transformers, as presently to be explained, all contain an iron core, which has to be magnetised and demagnetised 200 times a second, or 6,000,000 times a year. The total weight of iron cores in the whole of these transformers will be certainly not less than 400 tons, and it will require at least 400 kilowatts to maintain the magnetisation of these cores. If these transformers are connected with the circuits only, on the average, 4,000 hours a year, it is very easy to see that the magnetisation of the cores of the transformer will require not less than 1,600,000 Board of Trade units spent per annum, and this means at least 16,000,000lb. of coal, or 8,000 tons. Hence, in the United

* Cantor lectures delivered before the Society of Arts

Digitized by Google

Kingdom, we have buried away somewhere or other at least 400 tons of iron forming the cores of transformers, and these involve at least an expenditure of 8,000 tons of coal, costing some £6,000 sterling to maintain that magnetisation. It is, therefore, easily seen that the study of the construction of the alternate-current transformer, and its possible improvement, is one which is not at all unimportant from an engineering point of view.

I propose to assume in these lectures that the majority of those present are acquainted with the principal facts connected with the flow of alternating currents of electricity in inductive circuits, and to address myself more particularly to the study of alternating-current transformers from a practical point of view, discussing in the four lectures of this course the action of the transformer, the construction of the transformer, the testing of the transformer, and the employment of the transformer. You are all probably aware that an alternating transformer in its simplest form consists of two circuits of insulated wire, which are wound upon an iron core, and that this device operates to transform electric energy in such fashion that the flow of an alternating current through one circuit is made to produce another current in the second circuit, with an increase or decrease of current strength taking place at the expense of potentials. The transformer does no more than any lever, wheel and axle, or simple machine in transforming power from one form into another form. The general operation of the transformer or induction coil, in whatever form it may be taken, is then as follows: Through one of the circuits, called the primary circuit, is passed an intermittent, interrupted, or alternating current. This primary circuit is interlinked with a magnetic circuit, and the primary circuit establishes in the magnetic circuit an intermittent, interrupted, or alternating induction; the magnetic circuit is interlinked with a secondary circuit, and the variation of magnetic induction in the core creates an E.M.F. in the secondary circuit, which at any instant depends upon the rate of change of the total induction linked with the secondary circuit.

As the word "induction" will very frequently be mentioned during the succeeding lectures, it is exceedingly important there should be no ambiguity in your minds as to the meaning of this term. We may help ourselves by regarding the analogy of conducting circuits and magnetic circuits. Consider a conducting circuit in which an electric current exists. As long as the circuit is closed we recognise the presence of the current, either by heat produced in the conductor or by electrolysis, and by various magnetic and dynamical actions in the medium round it. We select some one of these effects, say the electrolytic effect, and we base our quantitative definition of current strength upon it; thus, for instance, the accepted definition of an ampere is that it is a current which in one hour deposits, electrolytically, 4·025 grammes of silver. The cause, whatever its nature, producing the current is called the E.M.F. If we draw any line linked with or surrounding the conductor conveying the current, whether that line be included in a magnetic material like iron, or a non-magnetic material like air, we find a physical action taking place in that path which is called magnetic induction, and the immediate cause of this magnetic induction we speak of as magnetic force. We measure this induction by one of the effects it can produce—namely, by the E.M.F. which it can set up in another conducting circuit linked with the magnetic circuit when that induction is suppressed or reversed at a given rate. Faraday showed that the proper measure of the total magnetic induction linked with any conducting circuit was the total quantity of electricity set flowing in the circuit when the magnetic induction is suppressed or reversed. In practical work it is better to abandon the rather academic phrase, "number of lines of force," or induction, so much used, and to think of the induction as a physical effect produced in the magnetic circuit, its value being reckoned in webers, the induction being produced in the magnetic circuit by magnetic force, just as electric current reckoned in amperes is produced in the conducting circuit by E.M.F. Hence we have this definition of a unit of magnetic induction. A unit of magnetic induction, called one weber, is an amount of induction which, when linked or unlinked with a circuit of one turn, and having a resistance of one ohm, causes one coulomb of electric quantity to flow round the conducting circuit. Generally speaking, if induction is measured in webers (one weber $=10^8$ C.G.S. units), we have the following relation between the magnetic induction, the number of turns or linkages which the secondary circuit makes round the line of the induction, the resistance in ohms of the secondary circuit, and the total quantity set flowing in the secondary circuit reckoned in coulombs.

Webers × linkages = coulombs × ohms.

Since one weber is a larger amount of induction than is met in any single transformer core or dynamo magnet, it is convenient to take the millionth part of this as the practical unit—viz., the *microweber*, and to commit to memory the following rule: microwebers × linkages = microcoulombs × ohms, and to recollect that one microweber is equal to 100 C.G.S. units of induction, or what would commonly be called 100 lines of force. In order to measure induction we require, then, a ballistic galvanometer as a practical instrument to measure electric quantity; and we can at once make a measurement of the induction in any magnet circuit by determining the quantity of electricity set flowing in a circuit of a known number of turns which is linked with this induction and then unlinked by withdrawing the circuit or reversing the induction. As a practical illustration of these methods it will be useful to make a measurement of the induction existing in this closed iron ring when it is magnetised by a current flowing round it. The ring, as you see, is wound over closely with one layer of wire, which we will call the primary circuit. If we measure the mean perimeter of the ring and count the number of turns, it is a simple matter to obtain the number of turns per centimetre. If a current measured in amperes is set flowing through this circuit, then it can easily be shown that the magnetising force acting upon the iron is equal to $1\frac{1}{4}$ times the turns of wire per centimetre, multiplied by the ampere current flowing through the circuit.* This magnetising force produces in the iron a certain magnetic induction which is measurable in microwebers. In order to find out the magnitude of this induction, we put upon the ring a secondary circuit of a known number of turns. We then employ a ballistic galvanometer suitable for measuring electric quantity, and we must first calibrate this ballistic galvanometer to determine the excursion or throw of the needle when a given quantity of electricity measured in microcoulombs is sent through it. This is most easily done by charging a condenser of half a microcoulomb by means of a standard cell having an E.M.F. of 1·5 volts, and discharging this quantity of $1{\cdot}5 \times {\cdot}5 = \frac{3}{4}$ microcoulomb through the galvanometer. This produces a certain throw or excursion of the needle, and we may then assume that for any other throw of the needle the quantity of electricity producing it is proportional to the throw as determined by the above calibration. In order to measure the magnetic induction in the iron circuit, all that we have to do then is to connect the secondary circuit having a known number of turns, and the resistance of which, added to that of the galvanometer and connecting wires, must be determined in ohms, and observe the throw of the galvanometer needle, which is produced when the primary current is reversed. Ascertaining

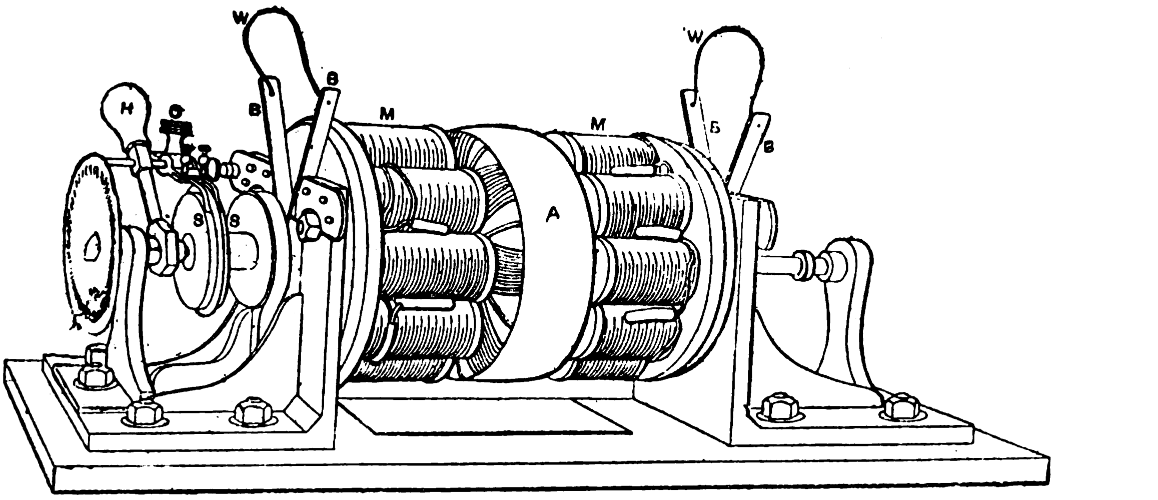

Fig. 1.

* *Vide* "The Alternate-Current Transformer," Fleming (new edition), vol. i., p. 23.

Digitized by Google

from the previous calibration the electric quantity measured in microcoulombs represented by the throw, we multiply that number by the total resistance of the secondary circuit, including the galvanometer, measured in ohms, and divide the product by the number of linkages or turns of the secondary circuit. This quotient gives us double the induction measured in microwebers existing in the iron core at the time when the steady current is flowing through the primary circuit, hence the induction is at once measured in microwebers.

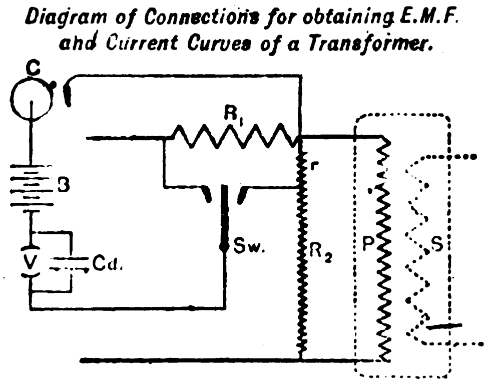

Fig. 2.

Returning then to the alternate-current transformer, we may classify transformers, converters, or induction coils, as they are also called, according to their construction and their use as follows: transformers may be (*a*) iron-core transformers, with a core wholly or partly of iron; (*b*) air-core transformers, with a core or magnetic circuit wholly of non-magnetic substance. Iron-core transformers may be (*c*) closed iron circuit transformers, with a magnetic circuit wholly of iron; (*d*) open iron circuit transformers, with a core partly of iron. Transformers may be

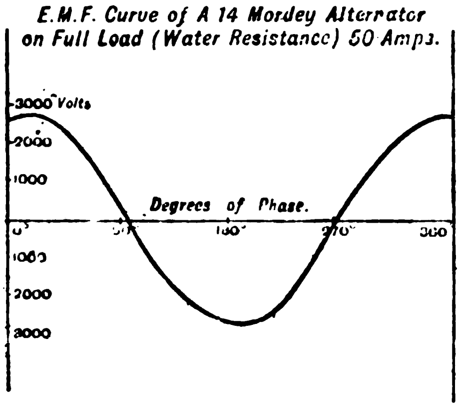

Fig. 3.

used (*e*) to transform a potential difference in a constant ratio, in which case they are called constant-ratio transformers; (*f*) to transform a current strength in a constant ratio, in which case they may be called constant transformers. The transformers may be employed (*g*) to raise pressure or current, and they are then called "step-up" transformers; (*h*) to lower pressure or current, and then they are called "step-down" transformers. This is not an exhaustive classification, but it is sufficient for practical purposes. By far the most important member of the group is the constant-potential closed

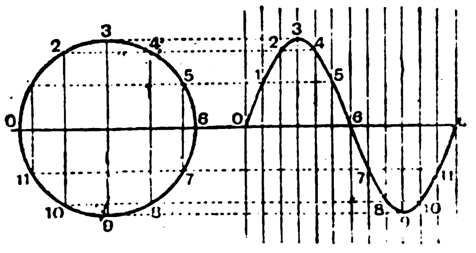

Fig. 4.

iron circuit transformer employed with alternating currents taken from a constant-potential primary circuit. This may be considered from its importance to be the chief of the clan, and to it, therefore, we shall pay most attention. In order to possess a complete knowledge of the operations and action of such a transformer, we require to know the nature of the operations going on in all parts of it at the same instant. We have seen that the broad general action of the transformer as employed with alternating currents is as follows: if an alternating primary current is passed through the primary circuit it acts upon the iron core with an alternating magnetic force, and creates in the iron core an alternating magnetic induction. If a secondary circuit is also wound round the same iron core, the periodic variation of magnetic induction in the magnetic circuit creates a periodic E.M.F. in the secondary circuit, and if that circuit is closed, creates in it a periodic secondary current. The method which of late years has proved most fertile in adding to our real knowledge of the subject of the

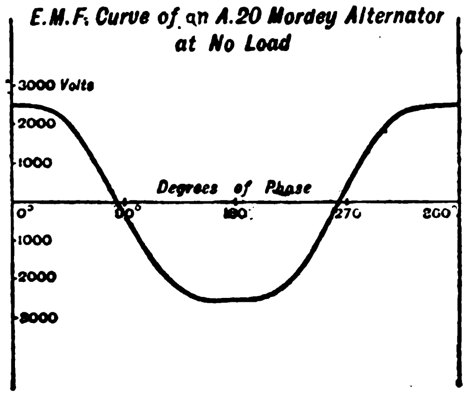

Fig. 5.

transformer is that of delineating graphically the various periodic quantities concerned by a process which is called alternate-current curve tracing. It is, therefore, necessary to study this process in some detail. Suppose that we have an alternating-current dynamo or alternator in operation we know that the potential difference between the terminals of this machine undergoes periodic variation, and that it passes from one maximum in one direction to another maximum in an opposite direction. At any instant the machine is producing an

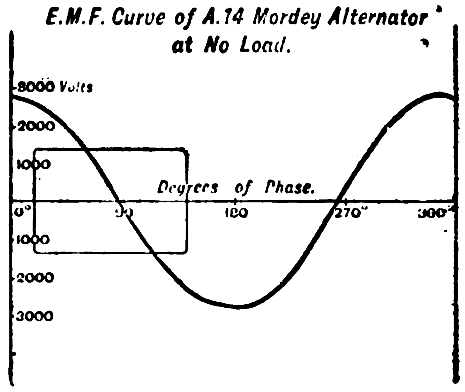

Fig. 6

E.M.F. which is called its instantaneous value. Suppose that the alternator terminals are connected to a condenser, the potential difference of these condenser plates follows the same law of variation as the E.M.F. of the machine. If the condenser is removed at any instant and the potential difference

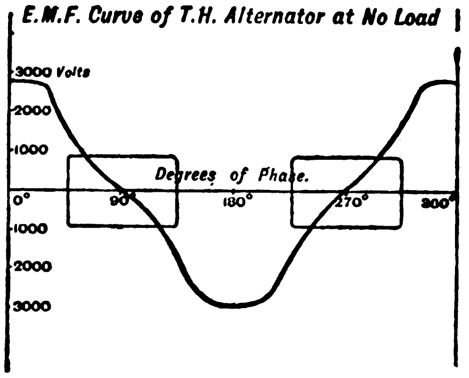

Fig. 7.

of its plates examined, that will give us the potential difference of the terminals of the alternator or the E.M.F. of the alternator at the instant when the condenser was disconnected. The practical arrangements made for doing this which I have found it convenient to use, are as follows: A small alternating-current motor (see Fig. 1) has its field magnets excited by a constant continuous current, and its armature traversed by a current coming from the alternator under examination. The shaft of this alternating-current motor carries an ebonite disc, on which is placed a small steel slip. As

Digitized by Google

the disc rotates the steel slip passes at each revolution underneath two small steel springs, lightly touching the ebonite disc. The steel slip, therefore, electrically connects these springs (which are otherwise insulated) together, and this connection takes place at each revolution. The two springs are carried on an insulated bar, which is capable of being moved round an arc

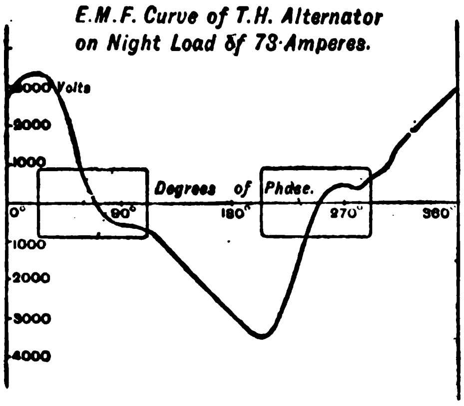

Fig. 8.

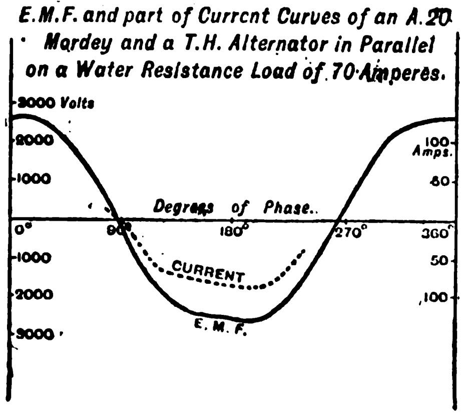
of a circle in such a manner that the instant when the springs are connected together can be altered and determined by the angular position of the rocking bar carrying the two springs as read off on a scale. If this little alternating-current motor is started in step with the alternating-current machine, it will keep in step with it, and will close the circuit of the two springs once during every revolution at an instant during the complete phase of the E.M.F. depending on the position of the springs.



Figs. 9.

These two springs, constituting the revolving contact breaker, are connected in series with a small battery of lithanode cells, B (see Fig. 2), and these again with an electrostatic voltmeter, V.

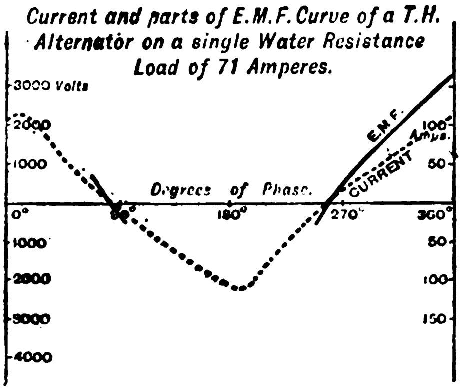


Fig 10.

across the terminals of which a condenser, Cd, is joined. This appliance may then be employed to determine the form of the curve of an alternating current or an E.M.F. as follows: Suppose it be desired to determine the curve of E.M.F. of any alternator, the contact-breaker is joined across the terminals of the alternator, and the reading of the voltmeter is taken as the rocking arm carrying the springs is moved round by steps through an angular interval corresponding to one complete period. At equal intervals during the movement the electrostatic voltmeter is read, and in order to bring the readings within the best part of the scale of the voltmeter a selected number of the cells of the battery, B, are placed in series with the voltmeter so as to add a known E.M.F. to the E.M.F. being measured.* By the employment of a revolving contact-breaker of this form, a number of curves were taken from the alternating-current machines in the City of London

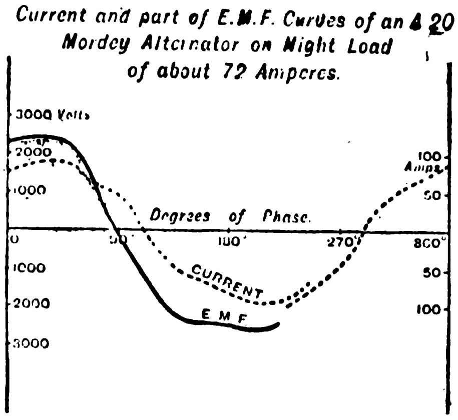

Fig. 11.

electric lighting station at Bankside, some of which are shown in the accompanying figures.

Fig. 3 represents the E.M.F. curve of a Mordey alternator on full load, the load being a water resistance. It will be seen that the curve of E.M.F. is not very far from a simple periodic or simple sine curve as shown in Fig. 4. Fig. 5 shows the E.M.F. curve of a larger Mordey alternator at no load, and Fig. 6 shows the manner in which the E.M.F. curve at no load is related to the position of the pole-piece represented by the rectangular line. The E.M.F. curve of an alternator is, however, not by

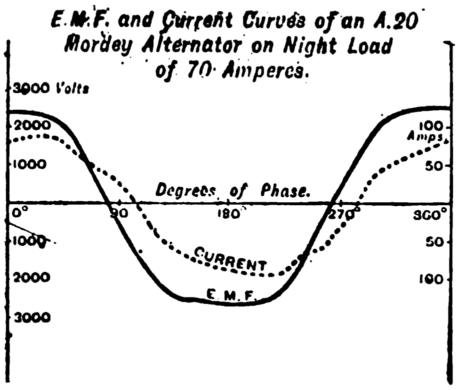

Fig. 12.

any means always so nearly a simple periodic curve. Fig. 7 represents the electromotive curve of a Thomson-Houston alternator taken at no load, the position of the field poles with respect to the E.M.F. curve being shown by the square

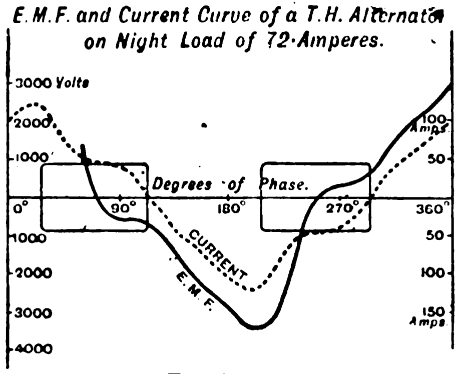

Fig. 13.

rectangles in the figure. Fig. 8 shows the E.M.F. curve of the same machine when working on a highly inductive load of transformers. In order to determine the form and relative position of the current curve, all that is necessary to do is to put in series with the alternator circuit a non-inductive resistance sufficient to carry without sensible heating the outgoing current. By connecting the revolving contact-breaker and associated voltmeter with the terminals of this non-inductive

* For further details see "The Alternate-Current Transformer," Fleming, vol. i. (new edition), p. 521.

Digitized by Google

resistance, we can delineate the curve of fall of potential down the non-inductive resistance, which is identically the same thing as the curve of current in the resistance.

In this manner have been determined the current curves taken from the above-mentioned machines, both on inductive and non-inductive loads. Fig. 9 shows the E.M.F. curve and part of the current curve of a Mordey and Thomson-Houston alternator on a water resistance; and Fig. 10 shows the current curve and part of the E.M.F. curve of a Thomson-Houston alternator working on a water resistance. These diagrams show that when an alternator having an E.M.F. of 2,000 volts is working on a water resistance this load is an absolutely non-inductive load, the current curve being practically perfectly in step with the E.M.F.

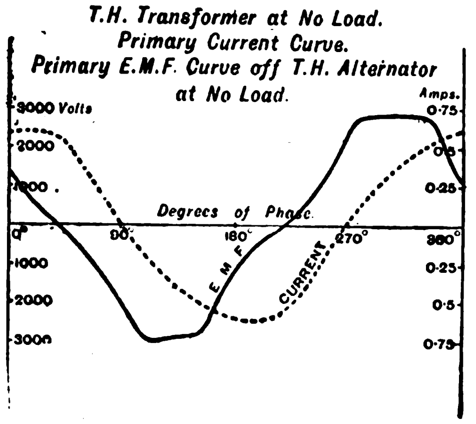

FIG. 14.

This leads to the conclusion that in testing a high-tension alternator for efficiency it is quite sufficient to load up the machine on water resistance to measure the current going out of the machine as ordinarily measured on an alternating-current ammeter, to measure the difference of potential at the terminals of the machine as measured on an alternating-current voltmeter, and to multiply the values of the two readings together, and thus obtain the true power in watts being given out by the machine on the water load. There is no question of difference of phase in this case. If, however, the alternator is working upon an inductive load, such as a number of transformers lightly loaded, then the current curve lags behind the E.M.F. curve by a definite amount at the zero value. This is shown in curves (Figs. 11, 12, and 13) giving respectively the E.M.F. and current curves of a Mordey alternator, and a Thomson-Houston alternator working on transformers lightly

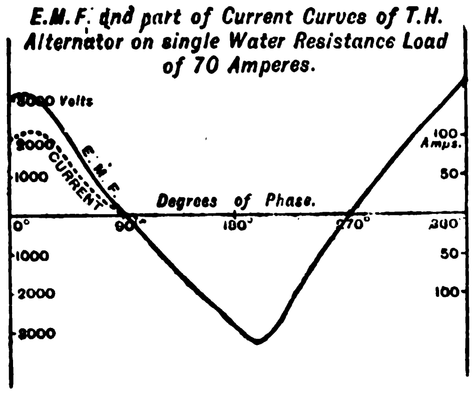

FIG. 15.

loaded. It will be seen that the difference of phase between the current and E.M.F. curves is different at different parts of the curve; in the case of the Thomson-Houston alternator there is no difference of phase between the maximum values of the current and E.M.F., but a considerable difference between the zero values. In the diagram of the Thomson-Houston alternator the position of the field poles is shown by the square rectangles, which, therefore, indicate the manner in which the E.M.F. curve is related to the field poles in the machines. It must not be supposed that the form of the current curve or of the E.M.F. curve is a fixed attribute of the alternator—that is to say, we cannot speak of the E.M.F. curve of an alternator as if it were something unchangeable and peculiar to that machine. It often largely depends upon the nature of the load. Thus, for instance, in Fig. 14 is shown the form of the E.M.F. curve of a Thomson-Houston alternator when very lightly loaded, and in Fig. 15 is shown the E.M.F. curve of the same machine when loaded on a non-inductive resistance to a fair proportion of its full load; whilst on referring to Fig. 13 we see the form of the E.M.F. curve of the same machine when working on an inductive load, and it will be noticed how very different in form are those three curves. Generally speaking, in a machine like the Mordey alternator with a very small armature reaction, there is very little change in the form of the E.M.F. curve with the nature and amount of the load on the alternator, but in the case of a machine like the Thomson-Houston or Westinghouse alternator with a large armature reaction there is a very considerable change in the form of the E.M.F. curve which changes in the amount and nature of the load. In the above cases the form of the E.M.F. curves have been set out graphically in what are called wave diagrams, in which the horizontal ordinates represent time, and the vertical ordinates represent the magnitude of the quantity which is varying, whether E.M.F. or current. For some purposes this method is not so con-

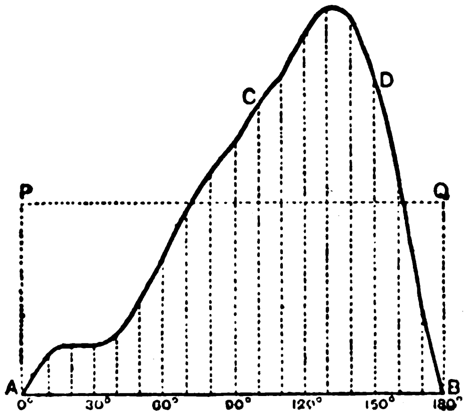

FIG. 16.

venient as that of setting out the curves in the form of polar diagrams.

The differences between these two methods — graphically delineated a periodic quantity—are shown in Figs. 16 and 17. In Fig. 16, part of the curve of the E.M.F. of a Thomson-Houston alternator on an inductive load is shown. In Fig. 17 the same quantity is delineated in a polar curve. Instead of drawing vertical ordinates at equal distances to represent the instantaneous values of E.M.F., radii are drawn from a point, O, at equal angular intervals, the magnitudes of which are respectively proportional to the instantaneous values of the periodic quantity. A curve, B C D, is thus obtained which is called a polar curve. It has this interesting property, that if we find the area of the polar curve, and describe a semicircle on a line, P Q, passing through the pole, O, the area of which is equal to the area included by the polar curve, B C D, it can easily be shown that the radius of this semicircle represents the square root of the mean of the squares of all the radii of the polar curve. This quantity is now generally called the R.M.S. value, or the root-

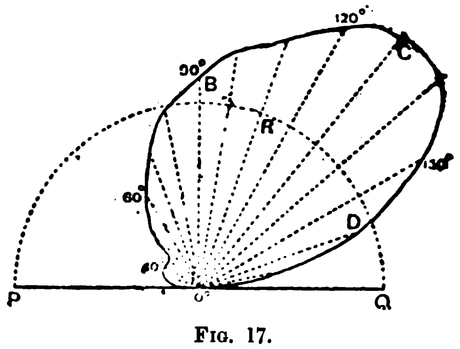

FIG. 17.

mean-square value of the periodic quantity. By some writers it has been called the effective or virtual value. Ordinary alternating-current ammeters and voltmeters give, as is well known, the R.M.S. value of the periodic quantity they are measuring.

Returning to Fig. 16, if we construct a rectangle, A P Q B, equal in area to the area included by the wave curve, A C D B, then it is easily seen that the height of this rectangle—namely, A P—represents the true mean value of the periodic quantity represented by the ordinates of the wave curve. In the case of any periodic quantity, such as a periodic E.M.F. or current graphically delineated, it is found convenient to have a term to denote the ratio between the true mean value of the curve ordinate and the root-mean-square value, and this is called the form-factor of the curve.*

(*To be continued.*)

LEGAL INTELLIGENCE.

THE HOPKINSON PATENT.

The petition by Dr. John Hopkinson, F.R.S., and the Westinghouse Electric Company, Limited, for the prolongation of letters patent granted to Dr. John Hopkinson in 1882 for a term of 14 years, for an invention of "improvements in distributing and measuring electricity and in apparatus to be employed for those purposes," was heard on Wednesday by the Judicial Committee of the Privy Council. The Court was constituted as follows: Lord Hobhouse, Lord Macnaghten, Lord Davey, and Sir Richard Couch.

The petition being one of great importance to the electrical industry, the hall of the Judicial Committee of the Privy Council was unusually crowded by counsel, specialists, and representatives of various municipal corporations. Amongst the opponents of the prolongation being Messrs. Crompton and Co., Limited; Callender's Bitumen Telegraph and Waterproof Company, Limited; the municipal corporations of Liverpool, Nottingham, Glasgow. Edinburgh, Dundee, Aberdeen, Blackburn, Oldham. Harrogate, Burnley, Dewsbury, Lancaster, Brighton, Belfast, Sunderland, Bradford, and Hull, and the National Electric Supply Company. Among the specialists in attendance were Lord Kelvin, Sir F. Bramwell, Prof. Boyes, Dr. Hopkinson, and Prof. Kennedy, the latter being the only specialist whom it was intended to call on behalf of the objectors

Mr. Moulton, Q.C., Mr. Roger Wallace, Q.C., and Mr. A. J. Walter appeared for the petitioners; Mr. Cripps. Q C., Mr. J. C. Graham, Mr. Bousfield, Q.C, and Mr. C. E. E. Jenkins, Mr. Terrell, Q.C., and Mr. C. Fleetwood Pritchard, Mr. J. C. Graham, Mr. W. Neill, Mr. A. J. Ashton, and Mr. C. E. E Jenkins (for the Birmingham Electric Supply Company, Limited), appeared for various objectors; and the Attorney-General, Mr. Henry Sutton, and Mr. Dennis appeared for the Crown.

The petitioners' case, in brief, was that prior to the invention patented by Dr. Hopkinson there were numerous difficulties in the way of the distribution of the electric current to incandescent lamps which the inventor claimed to have removed, and at the same time to have effected an enormous saving in the cost of the copper necessary for the construction of the main conductors, such saving amounting, in the case of the licensees of the patent, to a total of over £220,000. The invention introduced what is known as the "three-wire system." From want of capital Dr. Hopkinson found so much difficulty in getting his invention before the public, and in protecting his legal rights, that he was compelled to assign his rights, except in the legal estate, to the Westinghouse Company (the joint petitioners), who had worked it since 1889, and granted numerous licenses. The company, on their part, claimed that they had done a public service by coming to the assistance of the inventor, and making his invention of great public utility, but, as they had sustained a loss, they alleged, up to the present time, through the heavy legal and other expenses incurred of over £7,000, they prayed for the prolongation of the patent for another 14 years.

Before the Court heard Mr. Moulton in support of the above case, the **Attorney-General** took a preliminary objection. On the face of the petition Dr. Hopkinson had sold his interests in the English and German patents to the Westinghouse Electric Company for a sum of £19,750. While admitting the merit of the invention he submitted that Dr. Hopkinson had been adequately remunerated in respect of it by the amount which he had received from the company, and that as the inventor had thus been adequately remunerated for his invention the company were not entitled to claim a prolongation of the letters patent. The Attorney-General then quoted the judgment delivered by Lord Watson in the Bower-Barff patent case.

Mr. Moulton, Q C., for the petitioners, submitted in reply that the patent was one of very great merit, and the remuneration had been inadequate. Immediately after taking out the patent the petitioner used every endeavour to procure the adoption of his invention, but electric lighting was in its infancy and central lighting installations were so hampered by legislative provisions that for the first six years of the patent there was practically no opportunity for its application. A patentee who sold his rights in a patent did not thereby destroy the claim of the person who acquired the patent to the favourable recognition of their Lordships

The **Attorney-General** replied, and

Lord Hobhouse said their Lordships were of opinion that the objection raised by the Attorney-General arising on the face of the petition must prevail, and, therefore, their Lordships could not report to her Majesty in the way which was necessary for a prolongation of the patent. Their Lordships would give their reasons on some future date. They would allow one set of costs.

COMPANIES' MEETINGS AND REPORTS.

BRITISH ALUMINIUM COMPANY, LIMITED.

Directors: R. W. Wallace, Q.C., 21, De Vere-gardens, Kensington, W., chairman; A. S. Bolton, J.P., Moor Court, Oakamoor, N. Staffordshire; A. A. Common, LL D., F.R.S., 63, Eaton-rise Ealing, W.; Harvey du Cros., 14, Regent-street, London, S.W.; Robert Heath, J.P., Greenway Bank, Stoke-on-Trent, Staffordshire; E. Ristori, A.M.I.C.E, 2, Halkin-street, Grosvenor-place, S.W. Secretary: Charles F. Jones.

Directors' Report: In presenting their first annual report to the shareholders, the directors express their satisfaction in being able to state that the several factories of the Company are so far completed that the production of aluminium by the cheapest known processes and from entirely British raw material is now in successful operation. The acquisition of the necessary elements for the cheap production of this metal has been effected on favourable terms. Since the formation of the Company the following works have been carried out: (*a*) Bauxite mines at Glenravel (co Antrim) have been opened out and arrangements made that will assure an unlimited supply. (*b*) A large chemical factory has been built at Larne (the nearest harbour to the mines) and equipped with apparatus and machinery equal to the production of several thousand tons of alumina per annum under Dr. Bayer's process, the patents for which are owned by the Company. This factory is now in successful operation, and the alumina made is used at the Foyers factory. (*c*) The patent rights acquired by the Company to protect the production of aluminium, also cover the production of carbide of calcium, and the Company has granted to the Acetylene Illuminating Company, Limited, a license to manufacture this product. The directors expect that at an early date considerable profit will be derived from this source. (*d*) The freehold estate of Foyers, on Loch Ness, containing suitable water power, has been bought, together with the water rights of adjacent properties. The necessary engineering works have been carried out, comprising a long tunnel through the rock, lines of pipes, buildings, turbines, dynamos, furnaces, etc., and the factory is now in operation. (*e*) The Milton Factory acquired from the Cowles Syndicate Company, Limited, has been greatly improved and enlarged, by the erection of new buildings, a complete new rolling plant, other machinery, and additional furnaces. This factory had been in full and profitable work for some months. The directors, having found that aluminium manufactured according to certain of the Company's patents, has been imported into this country, are taking steps to stop further importation of the metal The directors have now resolved to issue the balance of the preference shares in order to provide for an increased output of metal. According to the articles of association, two of the directors, Messrs. A. S Bolton and A. A. Common, retire by rotation, and, being eligible, offer themselves for re-election. The auditors, Messrs. Crewdson, Youatt, and Howard, also retire, but offer themselves for re-election.

The first general meeting of the above Company was held on Thursday last at the Westminster Palace Hotel. The chair was taken at 12 30 by Mr. R. W. Wallace, Q.C.

After the minutes of the last meeting had been read, the **Chairman** explained to those present the position and objects of the Company. He said that he wished to draw attention to the fact that there was no connection between "the British Aluminium Company" and the "Aluminium Company." The latter undertaking did not produce aluminium, but only manufactured the aluminium when produced by others. There were three other places in which aluminium was now being manufactured—*i.e.*, at Neuhausen, on the Rhine, at Niagara, and at Froges, in France. With the company whose works were at Neuhausen the British Aluminium Company were on most friendly terms, and they had entered into a mutual agreement by which the German company would not import their productions into the United Kingdom. He could not say, however, that the relations with the American company were so satisfactory, as it had not yet acknowledged the patent rights of his Company. As the Niagara people were importing aluminium into England a legal action was pending. The chairman afterwards explained the English Government had acknowledged their patent rights and were paying royalty accordingly. After referring to the great reduction in the price of aluminium during the past 10 years, Mr. Wallace explained that the Company decided in the early days of its existence that the Neuhausen process was the best. The directors accordingly decided to take up a strong position, and to secure as much of a monopoly as possible. They accordingly acquired the whole of the patent rights of the process, a full control of the raw material they required, and ample water rights. They also entered into successful negotiations with the Cowles Company at Stafford, by which their interests were merged into the British Aluminium Company. The directors then acquired the mining rights over certain bauxite deposits in County Antrim, Ireland, at the low royalty of 6d. per ton. That was equivalent to paying only 2s 6d. for the raw material required to manufacture one ton of aluminium. The five tons of bauxite so required were reduced by a chemical process to two tons of pure alumina at the Company's works at Larne, and then exported to Foyers on Loch Ness. At this place they had purchased an estate of 8,000 acres and water rights over 100 square miles. That enabled them to set to work without an Act of Parliament, and the estate was acquired on such advantageous terms that the cost of the water power was practically nothing. The aluminium produced at the works was taken to Milton, in North Staffordshire, where it was manufactured into whatever commercial form may be desired. Mr. Wallace then referred at some length to the details of the Foyers works, which were described fully in our issues of April 24 and May 8, 1896. He then moved the adoption of the report.

Lord Kelvin seconded the adoption of the report, and congratulated the shareholders that their first report should be such a good one. He had personally inspected the works last September, and then did not believe it possible the aluminium could be produced at Foyers at such an early date as July this year. Such rapid progress reflected great credit on all concerned. He was pleased to note the way the Scotch people had welcomed this new industry, and thought that

Digitized by Google

the value of the water power now running to waste in the Highlands was more likely to be utilised. He considered that the Foyers plant was practically the first water-power plant in Great Britain, and he hoped that in Scotland especially it would give rise to a number of transmission of power schemes which would enrich the land.

The motion for the adoption of the report was then put and carried *nem. con.* The retiring directors were then re-elected, as were also the auditors of the Company.

After a vote of thanks the shareholders present adjourned to an adjoining room, where a number of samples of aluminium goods were on view. The domestic utensils, such as stew pans, kettles, etc., were strongly in evidence, as the sanitary nature of aluminium vessels would warrant. The British Aluminium Company will not, however, undertake the manufacture of such ware, but will confine themselves to the supply of sheet and wire aluminium, or of the metal in ingots and castings.

UNITED RIVER PLATE TELEPHONE COMPANY, LIMITED.

The tenth annual general meeting of this Company was held on Tuesday at Winchester House, E.C., Mr. J. Irving Courtenay presiding.

The **Chairman**, in moving the adoption of the report, a summary of which was given in our last issue, congratulated the shareholders on the improved condition of their property. The results of the past year's working, to March 31, were better and their prospects looked brighter, and the directors therefore recommended a dividend of 4 per cent. on the paid-up share capital, being an increase of 1 per cent. upon the distribution of the previous year. Matters changed rapidly in the Argentine Republic, and periods full of promise had been suddenly succeeded by gloom and anxious times. It was therefore all the more gratifying to observe the increasing steadiness and stability of affairs generally on the River Plate, by which the Company had profited to an extent which had quite equalled their expectations. The system of accounts had been altered, the receipts and expenses having been taken at the actual sterling value each month instead of at the par of exchange, as heretofore. The gross receipts had been £48,744, as against £36,673 in the previous year; and the working expenses in the Argentine had been £24,967, as against £17,555. To give a first-class service such as the Company now afforded it was necessary not only to have the plant in good working order, but that it should be handled by intelligent and skilful operators, who naturally commanded good wages. Their subscribers continued to augment, there being a total on March 31 of 6,231, or an increase of 433 for the year. Exchange had also been more favourable to them. Their plant generally was in very good order, but a large continuous outlay was necessary owing to the opening of new streets and the erection of new buildings. Mr. Chappell, their general manager in the River Plate, reported that most of the important alterations and repairs to their outside lines and wayleaves, which were commenced over a year ago, were either finished or rapidly approaching completion and they would be of immense benefit to their service. The Provincial Telephone Company, in which they were largely interested, was steadily progressing and had had an increase of subscribers of something over 10 per cent.

Mr. F. Jones, managing director, seconded the motion, which was agreed to.

THE ALUMINIUM COMPANY, LIMITED.

The report of the directors of this Company for the year ending June 30 states that the general business of the Company at Oldbury and the various undertakings in which the Company are interested are progressing satisfactorily. The accounts show a profit of £50,681 for the financial year. After providing for debenture interest amounting to £6,738 and other fixed charges, there remains a balance of £38,003, which, with the sum of £2,076 brought forward from last year, leaves the net profit at £40,080. The directors recommend the payment of a dividend of £15 per cent. on the "A" shares, which will absorb £9,000; that £10,000 shall be written off the works and £10,000 off the patents, leaving the sum of £11,080 to be carried forward. Ten thousand pounds has already been deducted from the amount at which the patents stood in the books of the Company. This represents the value of a portion of a patent which was included in the assets of the Company in the last balance-sheet, and has since been sold. Thirty-three thousand five hundred and twenty-three pounds out of the net profits for the year arises from the cash profit made on the sale of patents, etc., which were included among the assets of the Company at a nominal figure. During the year the £10 per cent. "B" debentures, amounting to £12,000, have been paid off, and it is intended to pay off the issue of £100,000 6 per cent. debentures on October 1, and issue in their place £90,000 4½ per cent. first mortgage debenture stock. The debenture debt will then be reduced by £21,800, saving an annual interest payment of £3,363. The contract with the Castner-Kellner Alkali Company, referred to in the last report, was duly completed, and the shares in that company held by this Company have been placed to reserve, and will, it is expected, in the near future add very materially to the Company's annual profits. The provisional contract of sale with the Mathieson Alkali Company has been confirmed, and all instalments due to the present time have been paid. The shares received in part payment have been treated in a similar manner to those held in the Castner-Kellner Alkali Company. Large works are about being erected by the Mathieson Alkali Company at Niagara Falls, and after January 1 the profits of this Company will further be increased by a royalty fixed at a minimum of £4,000 per annum. The American company, which was mentioned in the last report, was duly incorporated under the title of the Niagara Electro-Chemical Company, and are also erecting works at the Niagara Falls. It is expected these works will be completed in the course of the ensuing month. Negotiations for the sale of the British and Continental rights under similar patents to those sold to the Niagara Electro-Chemical Company are now proceeding.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Altona.—Tenders will be received up to July 21 by the Prussian State Railway Administration at their Altona office for the supply of about 21 tons of telegraph wire.

Mile End (London).—Tenders are invited by the Guardians for the electric lighting plant for their premises in Bancroft-road. The date is July 30, and particulars will be found in our advertising columns.

Bucharest.—Tenders will be received up to August 8 by the Roumanian Government (Department of Posts and Telegraphs) for the electric lighting of the new Posts and Telegraph building at Bucharest.

Vich (Spain).—The contract will be allotted by the municipal authorities of Vich on August 17 for the electric lighting of the town for 10 years from June, 1897. The annual payment proposed is about £800.

Amsterdam.—Tenders will be received up to 21st inst. by the Engineering Department, Plantage Lijnbaansgracht, Amsterdam, for work in connection with the establishment of telegraphic and telephonic lines. The amount is slightly under £2,000.

Hull.—The Corporation require tenders for the supply of an engine and dynamo to run 40 16-c.p. lamps for the lighting of the East District sewage pumping station. Further particulars may be obtained of Mr. A. E. White, borough engineer, Town Hall, Hull. Tenders, endorsed "Engine and Dynamo," are to be delivered to the borough engineer by 23rd inst.

Mexico.—Sealed tenders will be received by the secretary of the City Council of the city of Mexico, not later than the last day of August of the current year, for the lighting of the city by electricity. All information and conditions of tender, plan of the city of Mexico, etc., can be obtained on application at the Mexican Consulate, Broad-street House, New Broad-street, London.

Simla (India).—The Municipality is inviting tenders for lighting by electric light for a term of years the principal thoroughfares and buildings belonging to the Municipality. Tenders must be submitted by September 1 next. Should any proposal be accepted, the Municipality will afford the successful tenderer all facilities to extend the system of lighting to private houses.

Cologne.—Tenders are required by the Municipal Authorities for the construction and working of electric tramways in the city of Cologne to an aggregate length of 20·3 kilometres (12½ miles). Specifications, plans, and particulars are obtainable for 10 marks (10s.) from der Registrateur B, des Oberbürgermeisteramt, Köln, Germany, and tenders must be in by November 6.

Madras.—Tenders are invited for the lighting by electricity of Government House, Madras, including the banqueting-hall and aide-de-camps' bungalow, and also for the lighting of Government House, Guindy, including the military secretary's bungalow. For particulars application must be made to the consulting architect to the Government, Chepank, Madras. Tenders will be opened on November 11, 1896.

Lisbon.—The Royal Portuguese Railway Company want tender by July 22 for the supply of 10,000 porcelain insulators with galvanised iron supports, 200 sheets of asbestos (1 metre square by 2 millimetres thick), and about 2½ tons of galvanised iron wire. The tenders are to be addressed to the Chief of the Stores Department at Santa Apolonia Station, Lisbon and particulars can also be obtained at Paris, Rue de Châteaudun 28.

Blackpool.—The Corporation require tenders for the supply of coal and oil to the electricity department. Specifications may be obtained on application to Mr. Robt. C. Quin, borough electrical engineer, Corporation Electricity Works, West Caroline street, Blackpool, and sealed tenders must be delivered at the electricity works not later than 10 a.m. on 27th inst., addressed to the Chairman of the Electric Lighting Committee, and endorsed "Tender for Coal" and "Tender for Oils" respectively.

Bristol.—The Electrical Committee invite tenders for the supply of (*a*) pea nut coal washed, (*b*) pea nut coal, unwashed, to the electric lighting station, Temple-back, Bristol, for six or 12 months (at their option) from August 1. A copy of the specification and forms of tender can be obtained from Mr. Frank Wm. Prosser, secretary, Temple-back, Bristol. Tenders must be delivered by noon on 24th inst., addressed the Secretary, Electricity Department, Temple-back, Bristol, and endorsed "Tender for Coal."

Mexico.—The municipal authorities of the city of Mexico are prepared to receive proposals for the street lighting by incandescent

Digitized by Google

lamps for a period of eight years. Tenders should be sent in by August 31. The Secretary of State for Foreign Affairs has received from the British Consul at Mexico a pamphlet issued by the Municipal Council of the city containing particulars as to the tenders, and this may be seen on application to the Commercial Department of the Foreign Office between the hours of 11 and 6.

Voghera (Italy).—In view of the expiration of their contract with the local gas company in 1898, the municipal authorities of Voghera are desirous of receiving during the present year propositions for the lighting of the town either by the electric light or a mixed system of gas and electricity. The population is 16,000. Application should be made to L'Administrazione Comunale, Voghera, who will give all particulars necessary.

San Juan (Puerto Rico).—H.M. Secretary of State for Foreign Affairs has received from H.M. ambassador at Madrid a copy of a Spanish Royal Order which has appeared in the *Gazette* inviting tenders for the construction and working of a telephone system in San Juan de Puerto Rico. A deposit of 800dol. must accompany each tender, which will be considered on August 10. The copy of the Royal Order may be seen on application to the Commercial Department of the Foreign Office between the hours of 11 and 6.

Bray (Ireland)—The Township Commissioners invite tenders for (*a*) erection of a brick chimney, 100ft. high, (*b*) sundry alterations to existing buildings at the electric light and power station. Plans and specifications may be inspected at the Town Hall, Bray, between 10 a.m. and 4 p.m. Separate tenders to be given for Section A and B. Tenders, properly sealed, and endorsed 'Tender for Chimney" or "Tender for Alterations," as case may be, to reach Mr. P. MacDonnell, town clerk, before 10 a.m. on 20th inst.

Hull.—Tenders are required by the Electric Lighting Committee for the supply of best South Yorkshire hard steam doubled-screened nuts for 12 months ending June 31, 1897, in accordance with the conditions set forth in the form of tender, which may be obtained at the Electric Lighting Offices, Dagger-lane. The contractor will have to enter into the usual form of contract required by the Corporation. Tenders, endorsed "Double-Screened Nuts for Electric Lighting Station," to be sent, under seal, to the chairman of the Electric Lighting Committee, Town Hall, by noon on 30th inst. Mr. A. S. Barnard, borough electrical engineer, Electric Lighting Station, Dagger-lane.

Army Contracts.—The Secretary of State for War gives notice that tenders for specific quantities of the following articles will probably be invited from time to time during the next twelve months — namely: submarine mining electrical instruments, telegraph cable and wire, etc. Manufacturers who may wish to be applied to when tenders are required should address the Director of Army Contracts, War Office, Pall-mall, S.W., by letter, stating the particular articles which they manufacture, and the names of at least two well-known firms or public bodies who have purchased from them, and are in a position to certify as to the quality of their productions. Applications unaccompanied by references will not be noticed. Firms whose names are already on the War Office list need not apply, as forms for tendering will be sent to them in due course.

Egremont (Cheshire).—Tenders are invited by the Wallasey Urban District Council for the erection of an additional six-celled Fryer's patent refuse destructor, with Boulnois and Brodie's patent charging apparatus, Jones's fume cremator, steam-engine, and mortar mills, together with additional roofing buildings and electric lighting in connection with the existing refuse destructor works at Gorsey-lane, Poulton. Plans may be seen and specifications and forms of tender obtained on payment of £2. 2s., which will be returned on receipt of a bona fide tender, at the offices of the engineer and surveyor, Mr. Arthur Salmon, A.M.I.C.E. Separate sealed tenders, addressed to the chairman of the Health Committee, and endorsed "Destructor Contract D, E, F, or G," as the case may be, to be left at the office of Mr. W. Danger, clerk, Public Offices, Egremont, by 5 p.m. on 20th inst. The contractor will be required to enter into a bond, with approved sureties, for the performance of contract, which contract and bond will be prepared at the expense of the contractor.

Kingston (Jamaica).—The Colonial Government invite electric tramway contractors willing to undertake the establishment and working of a system of rapid transit to send in applications for the grant of a license by the Governor in Privy Council under the Tramways Law, 1895. In all applications the principal questions to which attention should be directed are the following: (*a*) the amount of capital which the applicants are prepared to subscribe; (*b*) the system which it is proposed to establish; (*c*) the mileage of lines to be laid; (*d*) the fares to be charged; (*e*) the frequency of the service; (*f*) the length of the license required by applicants; (*g*) the guarantee which the applicants offer for the satisfactory performance on their part of any obligations devolving on them. Plans of the city of Kingston and part of the parish of St. Andrew, showing the routes on which the present tramway lines are laid, and copies of the law under which licenses are granted and of the rules made thereunder by the Governor in Privy Council, may be seen at the office of the Crown Agents for the Colonies, Downing-street, London, S.W. All applications must be delivered not later than July 31, 1896, in a sealed packet, marked on the outside "Application for Tramway License," to the clerk of the Privy Council, Kingston, Jamaica. Kingston has its principal means of transit at present supplied by the Jamaica Street Car Company by horse tramcars, the entire length of lines laid being about 12 miles. The concession granted by the Legislature of the island to the Jamaica Street Car Company will shortly expire.

RESULTS OF TENDERS.

Ealing.—The District Council have accepted Messrs. W. Foord and Son's tender (£1,952) for extensions to the electric lighting station.

Wakefield.—The estimate of the Private Wire and Telephone Installation Company for providing and fitting telephones throughout the new municipal buildings has been accepted.

Puebla de Rugat (Spain)—A contract for electric lighting in this little town, which is in the province of Valencia, has been allotted to Messrs. Serra and Ramirez at 1,200 pesetas (£48) per annum for 10 years.

Plymouth.—The Town Council have accepted the tender of the British Insulated Wire Company for the supply of the underground electric cables required for Old Town, Ebrington, and Ham streets for £723, subject to the approval of the Local Government Board.

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,889.

Mile End.—The Vestry have rejected a proposal to apply for an order to light the parish by electricity.

Bournemouth.—The pier will most probably be illuminated and decorated by the electric light shortly.

Stockton.—The Board of Trade have agreed to extend the borough electric lighting order for another two years.

Dewsbury.—The electrical energy generated during three weeks ended June 20 was 2,605 units, against 1,044 units last year.

Hove.—The electric lighting company have applied to the Urban District Council for permission to increase the pressure of electricity.

Aston.—The District Council have adopted the specifications submitted by Mr. Vawdry for the extension of the electric lighting plant at the baths.

Lowestoft.—The General Purposes Committee have been instructed to take into consideration the advisability of the Town Council introducing the electric light.

Notting Hill Electric Lighting Company.—The Company have declared an interim dividend for the six months ending June 30 at the rate of 6 per cent. per annum, payable forthwith.

Bermondsey.—The Vestry have decided to oppose the application of the London and Brush Provincial Electric Lighting Company, Limited, for a provisional order for lighting the district.

Address.—We learn that Mr. A H. Vesey has relinquished his private practice as a consulting engineer, and has joined the firm of Messrs. Vaughan and Brown, Kirby-street, E.C., in a similar capacity.

Telegraph Construction and Maintenance Company.—The directors announce the forthcoming payment of an ad interim dividend of 12s. per share to all shareholders on the register on 13th inst.

Darfield.—The Urban District Council have resolved to invite Mr. Johnson (Tasker, Sons, and Co., of Sheffield) to make a tour of the township and give an estimate for the lighting of the streets with electricity.

Barrow.—The Corporation having had a report from Mr. E. Manville on electric lighting, with a map showing the positions of the proposed mains, have ordered a hundred copies of the report to be printed and distributed.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending July 12 amounted to £1,252, as compared with £1,186 in the corresponding week of the previous year, being an increase of £66.

Accumulators.—We have to acknowledge the receipt from the Elektricitäts-Gesellschaft Gelnhausen of their catalogue and price-list, dated June, 1896, of storage battery cells. The address of the company is Gelnhausen, Germany.

Bristol Tramways and Carriage Company, Limited.—The traffic returns for the week ending July 10 were £2,419. 5s. 7d., compared with £2,064. 8s. 5d. for the corresponding period of last year, being an increase of £354. 17s. 2d.

The Fastnet Lighthouse.—In reply to Sir J. Leng (Dundee), in the House of Commons last week, Mr. Ritchie (Croydon) said the amount already spent in connecting the lighthouse is about £2,600. The estimate for further expenditure is £850.

City of London Electric Lighting Company, Limited—Warrants for the payment of an interim dividend for the half-year ended June 30, 1896, at the rate of 6 per cent. per annum on this Company's preference shares were posted on Wednesday.

County of London and Brush Provincial Electric Lighting Company.—The directors have declared an interim dividend for the half-year on the first and second issues of preference shares at the rate of 6 per cent. per annum, payable on the 21st inst.

Blackburn.—The electricity supply fund shows that the total expenditure to December 31, 1895, was £25,783. 17s 3d., and the amount raised by loan was £22,000. The revenue account shows an income of £1,216. 1s. 9d., and an expenditure of £1,205. 1s.

Electrical Books.—A useful little book is the classified catalogue of electrical books which is issued by the W. J. Johnston Company, 253, Broadway, New York. It contains a description of every electrical book on the market, and its price in American coinage.

Digitized by Google

Halstead.—At the meeting of the Urban District Council the Lighting Committee reported that they had placed the report in the hands of a sub committee, who would ascertain how many people would be inclined to have private lights. The report was adopted.

Camberwell —The General Purposes Committee reported at the meeting of the Vestry that the National Telephone Company had commenced laying the cable underground in the Old Kent-road, in accordance with the permission granted by the Vestry in March last.

Gateshead —A number of members of the Corporation, accompanied by members of the Parliamentary Committee of that body, have visited Sunderland in order to look over the electric works in that borough, with a view to considering the desirability of having electric lighting in Gateshead.

City and South London Railway.—The returns for the week ended July 12 were £937, compared with £848 for the corresponding period of last year, being a decrease of £89. The total receipts for the half-year 1896 were £1,818, compared with £1,763 last year, being an increase of £55.

Brandon.—At the meeting of the Urban District Council the Chairman stated that he had seen Mr. Greener that morning in regard to the lighting of the west ward, and he told him that he had not yet received any tenders from the electric lighting company, but expected them every day.

Leatherhead.—The clerk stated at the meeting of the Urban District Council that he had received a letter intimating that a provisional order was to be applied for on or before December 21 empowering a company to supply Leatherhead with the electric light. The letter was allowed to lie on the table.

Direct United States Cable Company.—The Board have resolved to recommend a final dividend of 2s. 6d. per share, free of income tax, making, with the interim dividends already paid, 2¼ per cent. for the year ending June 30, and, after placing £7,500 to reserve fund account, carrying forward a balance of £4,235.

Burrelton.—The villages of Burrelton and Woodside being now formed into a special lighting district, there is some talk of discarding the oil lamps now in use and going in for electricity. There is a disused water power at the south end of the village which could be utilised for the producing power at small cost.

Newport (Mon.).—The electric light is progressing rapidly, and the cables are being extended in all directions. The provision of a sub-station in the basement of the town hall, on the Austin Friars side, at a cost of £900, is under consideration, and the new landing-stage for excursion traffic is to be provided with the light.

Watford.—The committee appointed to consider the question of appointing an electrical engineer reported that they had fully considered the applications received, and recommended the Urban District Council to appoint Mr. W. C. C. Hawtayne to fill the post. At the meeting of the Council the recommendation was agreed to.

Dissolution of Partnership.—The partnership existing between Mr. Bennett and Mr. Wm. H. Druce, under the style of "Bennett and Druce" was dissolved on June 26. Mr. Druce has taken offices at Temple-chambers, 33, Brazennose-street, Manchester, and will in future devote himself exclusively to the practice of consulting engineering.

Dublin.—A presentation of an illuminated address from the employés of the Dublin Electric Tramway Company, and several pieces of plate, was made last week to Mr. T. B. Halliday, superintendent of the line, on behalf of Mr. J. Clifton Robinson, on the occasion of his retirement from the managing directorship of the company.

Shoreditch.—At the meeting of the Vestry, Mr. Kershaw drew attention to the question of laying the electric mains, which, he said, was making very slow progress. At the present rate the work would take 32 weeks to complete, and under the circumstances the Vestry decided to sanction the employment of another gang of workmen to be set on Haggerston.

Anglo-American Telegraph Company.—The directors have resolved, after placing £6,000 to the credit of the renewal fund, to declare an interim dividend for the quarter ending June 30 of 12s per cent. on the ordinary stock, and 24s. per cent. on the preferred stock, less income tax, payable on August 1 to stockholders registered on the books of the Company on July 8.

Kingswood.—At the meeting of the District Council a letter was read from the electric light contractors *re* the purchase of their installation by the Council, wherein it was stated that they were willing to allow the offer to purchase to remain open a little longer. In conclusion, the letter stated that the question should be considered at the earliest opportunity, as it could not be delayed indefinitely.

Aluminium Company Debentures.—Messrs. Robarts, Lubbock, and Co. are instructed to receive applications for an issue by the Aluminium Company, Limited, of £90,000 4½ per cent. first mortgage debenture stock, at the price of £103 per cent., redeemable, at the option of the Company, on or at any time after October 1, 1906, at £110 per cent. at six months' notice. The list will close on or before Saturday, at 11 a.m.

Ealing.—The Electric Lighting Committee reported at the Urban District Council meeting that Mr. G. Thompson had applied to have the electric light supplied at his house at Waldeck-road. On the recommendation of the committee, the Council instructed the clerk to inform Mr. Thompson that his was the first application from Waldeck-road, and an extension of the mains could not be entertained until there were other applications.

Aberdeen.—The employés of the electric lighting station, Cotton-street, held their annual outing last week. The party, to the number of 14, went to Crieff, and during the early part of the day Drummond Castle was visited. In the afternoon the party sat down to dinner in the Commercial Hotel, Crieff, under the presidency of Councillor Johnston, convener of the Gas and Electric Lighting Committee. Perth was subsequently visited.

Battersea.—At the meeting of the Vestry no order was recommended by the Dusting Committee on a request from the Battersea Tradesmen's Club that Battersea Park-road between Latchmere-road and Victoria-road might be lighted by electricity. With reference to electric lighting, the County of London and Brush Company wrote informing the Vestry that they would not proceed with their application for a provisional order so far as the application related to Battersea.

Morecambe.—At the District Council meeting, a draft agreement for the purchase from the rector of land required for electric light work was approved, Mr. Thos. Parker, electrical engineer, Wolverhampton, being instructed to prepare the plans, estimates, and reports required by the Local Government Board and Board of Trade for enabling the Council to take over the undertaking of the Morecambe Electric Light and Power Company and establish a new electric light station.

Birmingham. — The following resolution was passed at a meeting of telegraph clerks: "That this meeting of the Birmingham Postal Telegraph Clerks' Association expresses its keen dissatisfaction with the evidence given and the proposed scale of pay submitted by Mr Lewin Hill to the Inter-Departmental Committee on Post Office Establishments, and respectfully urges that, far from removing grievances and allaying discontent, they will only aggravate and enhance them."

Levenshulme.—At the meeting of the Urban District Council the clerk read a letter from the South Manchester Electric Supply Company, Limited, stating that they were about to make an application to the Board of Trade for the grant of a provisional order for the supplying of electricity in Levenshulme. A letter informing the Council of a similar intention on the part of the Altrincham Electric Supply, Limited, was also read. The letters were referred to the General Purposes Committee for consideration.

City and South London Railway Company.—The accounts of the Company for the half-year ended June 30 show a balance, after providing for the debenture interest and the full dividend on the 5 per cent. preference shares, sufficient to allow the payment of a dividend on the consolidated ordinary stock at the rate of 1⅝ per cent. per annum, carrying forward a balance of £1,072 to the new account. The dividend for the corresponding period last year was at the rate of 1⅛ per cent per annum, the balance carried forward being £965.

Islington.—The Vestry having, like St. Pancras Vestry, retained the supply of electricity in the parish over which it exercises control in its own hands, has already expended or incurred liabilities amounting to £96,383. The demand for the electric light by private consumers has greatly increased, and is augmenting. Hence the Electricity Committee find it necessary to ask the Vestry to sanction an additional expenditure of £20,000. This it is proposed to raise by loan to meet the requirements of the undertaking.

Edinburgh.—At the meeting of the Town Council the Cleansing and Lighting Committee's report showed a deficit of £721, entirely due to the electric light, and of £3,287 on cleaning, but it was right to explain that in the expenditure was a sum of £4 800 as expenses in connection with the destructor case in the Court of Session, otherwise the committee would have had a surplus of £1,500 in the cleaning account. The total surpluses in favour of the committee were £5,959 and the net deficiencies £5,629—a net surplus of £330.

The London Tramways Question.—Next week a report of the Highways Committee of the London County Council will be presented on this subject. The committee adhere to their recommendation, that the Council should lease the lines to the two companies until 1910. They will report against the Council working the lines or using electric traction, and will adduce additional facts and figures in support of their recommendation and against the instructions from the Council carried at the instance of Mr. Baker.

Witton Gilbert.—At the meeting of the Parish Council the agreement with the Bearpark Coal Company, in reference to the poles at Dene Burn Cottages having been duly executed, was approved of. The Corlett Electrical Engineering Company's account was produced, showing a balance of £86. 3s. 2d. still due to them on contract and additions thereto, and, on the motions of Councillors Goodwin and Embleton, a further sum of £50 was ordered to be paid, leaving the balance over pending experts' examination and report.

Fulham.—The Electric Lighting Committee having recommended that a deputation be appointed to visit the towns of Leeds, Warrington, Oldham, Brighton, Bedford, and Portsmouth, for the purpose of seeing the destructors in operation and inspecting the electricity supply works, and that Messrs. Baxter, T. Davies, Tapp, and Terry do form the deputation, and that the expenses do not exceed £100, the matter was discussed at some length at the meeting of the Vestry. Eventually the report was referred back to the committee.

Catalogue.—We have received from the Universal Electrical Fittings Company, Limited, of Suffolk-road, Sheffield, their cata-

Digitized by Google

logue. The 40 pages of the list are fully illustrated, and the catalogue is a well-turned-out production. The company claim for their apparatus that they are distinguished by a high and uniform standard of insulation and for their large contact surfaces. Special attention is given to service switches, main cut-outs, and junction-boxes, and provision is made for pressures of 200 volts or more at the consumer's terminals.

Acton.—The surveyor read a letter at the Urban District Council meeting from Mr. Goddard with reference to purchasing Mr. Cohen's electric lighting works, stating that if the Council intended to purchase the works they must take all risk. Mr. Cohen could only guarantee the rent of his own premises, 3, Emmanuel avenue. The matter lay in a nutshell: either the Council would or would not purchase the works, but his client could not be kept waiting for the Council's decision for an indefinite period. The letter was referred to the Works Committee.

Huddersfield.—A special meeting of the council of the Chamber of Commerce has been held to confer with representatives of other chambers of the West Riding, with a view to obtaining an improvement in the telegraphic service between West Riding towns and the London Stock Exchange. On the motion of Mr. Bentley, seconded by Mr. Hooper, it was resolved to suggest to the Postmaster-General that messages to and from the London Stock Exchange to the West Riding towns should be transmitted through the direct wire of the Leeds Stock Exchange.

Perth.—Permission having been asked by the National Telephone Company to erect a line of poles along the public road between Perth and Crieff, the Chairman remarked at the meeting of the District Committee that they had a standing agreement with the Telephone Company. Colonel Sandeman stated that if they granted the permission asked, and branch wires were attached to the line, Perth and Crieff, it would then become a trunk line and therefore become Government property. It was agreed to grant the necessary permission on the usual terms.

Blackpool.—The Electricity and Tramways Committee have rescinded the following resolution: "That 4½d. per unit be the amount to be charged the Corporation until further notice for public electric light arc lighting in the borough," and have resolved that the Corporation be charged on the same basis as other consumers for electric energy supplied by this committee's department for public electric light arc lighting. The profit from the Corporation's electric lighting undertaking for the year ended March 25, 1896, has been placed to a renewal fund account.

Wednesbury.—At the meeting of the Town Council, Councillor Joynson called the attention of the Highway Committee to the fact that the Walsall Corporation had taken steps to purchase the tramways in their borough. Councillor Oldbury, chairman of the committee, said he was aware of the action taken by Walsall in respect to their tramways. He understood similar powers to those possessed by Walsall existed in Wednesbury, and the Council might depend upon it that if anything was done seemingly to the detriment of Wednesbury he would at once call the committee together to protect their interests.

Montreal.—The Stilwell-Bierce and Smith-Vaile Company have secured what is stated to be the largest contract ever given for a turbine installation. This contract comprises the development of the water power on the Richelieu River, which forms the outlet of Lake Champlain. The development will amount to about 21,000 h.p., which is to be transmitted electrically into Montreal, some nine miles distant, where it will be sold for various purposes. The contract price for the hydraulic installation is 550,000dol. (£124,000). The turbine selected is the "Victor," of which Mr. F. Nell, of 97, Victoria-street, London, is the foreign representative.

Walsall.—A memorial, signed by 75 residents and property owners in High street and Digbeth, was read at the Town Council meeting, praying for the extension of the electric lighting scheme to those parts of the town. The Mayor said he sympathised with the memorialists, but the matter could not be settled at once, because various details would have to be considered. He proposed that the memorial should be referred to the Street Committee to report to the General Purposes Committee, and, if necessary, to the Council. Mr. Williams seconded the proposition, remarking that the memorialists were only anticipating the wish of the Council. The motion was agreed to.

The Cost of Current in the City.—At the meeting of the Court of Common Council, Mr. Brooke Hitchen asked the chairman of the Commission of Sewers whether he had placed before the members of that body the question as to the desirability of approaching the electric lighting company with a view to its reduction of the cost of the electric current? Mr. Turner, in answering in the negative, said the citizens had the matter in their own hands, as if they combined and said they would not use the current unless a reduction was made in the cost the company could do nothing else. As regards the public lighting, the Commission had made, he thought, an excellent bargain.

Redditch.—A letter was read at the meeting of the Urban District Council from the Manchester Edison-Swan Company stating that they proposed to apply to the Board of Trade for a provisional order authorising them to supply electricity for lighting and other purposes in the district, and asking their permission to make the application. Some time ago the Local Board caused an enquiry to be made and an estimate prepared of the cost of lighting the town by electricity, but no definite steps were taken in the matter. The opinion was generally expressed that if electric lighting was introduced the Council should undertake the work themselves, but the further consideration of the subject was deferred.

Forfar.—At a meeting of the County Road Board the County Clerk stated, in connection with the arrangement for the transfer of the trunk wires from the National Telephone Company to the Post Office, that the County Council assessor had these under consideration. He had been instructed to communicate with the clerk of that body, as well as with Lord Camperdown, and at the same time petition the Postmaster-General, requesting that in connection with county matters the same facilities be afforded as hitherto. Consideration of an application by the National Telephone Company for permission to lay an underground cable from Dundee to the Strips of Craigie was delayed until a report had been received from the Dundee District Committee.

Waterford.—At the meeting of the Corporation a letter was read from the secretary of the General Post Office, London, informing the Council that their resolution calling for an extension of the trunk telephone trunk system so as to put Waterford into direct telephonic communication with Dublin and Cork, would receive careful consideration from that Department. Mr. John E. Redmond, M.P., wrote acknowledging receipt of the resolution, and stated that it would give him great pleasure to aid in the effort now being made to extend the telephonic communication to Waterford. Mr. Power, M.P., also wrote and promised to confer with the gentlemen named in the resolution as to the best way to advance the views held by the members of the Council on the subject.

Leeds.—A meeting of the Highways Committee of the Leeds City Council has been held to consider a proposed agreement between the Corporation and the National Telephone Company for charges for way-leaves for wires, either overhead or underground, within the city. A special sub-committee, which had been appointed to discuss the matter, recommended that the company should be charged 2s. 6d. per subscriber for the first year, 3s. 9d for the second year, and 5s. for the third and subsequent years. An amendment was moved by Alderman Firth that the committee should enforce the Manchester terms, including 5s. per subscriber and 5s. per junction-box per year. The voting was equal, and therefore no decision was arrived at. The matter will again be considered by the committee.

Swansea.—It is now stated that in the new provisional agreement arrived at between the Corporation and the tramway company with a view of reviving what is known as the triple scheme, that so far from the company gaining any advantage the reverse is the case, the Corporation having secured the point on which it placed so much insistance—viz., complete control of the £32,000 which is to be advanced the company for the purchase of new plant, etc.—and it further gets the company to pay for the erection of transformers, estimated at £3 000. This is the point on which negotiations broke down six months ago. The company will be asked to pay for the transformed current. At a meeting of the Town Council, an amendment was passed that tenders be invited by advertisement for lighting the market by electricity upon the specification prepared by Mr. Manville, consulting electrician.

Bangor.—At the meeting of the City Council, Mr. W. P. Matthews moved that the resolutions of the Council dated October 9, 1895, and June 3, 1896, to apply to the Board of Trade for a provisional order for the electric lighting of Bangor be rescinded. He maintained that the Council would lose nothing by adopting his motion, because it was evident that no outsider could go in for a provisional order without the consent of the Council. Taking into consideration the expenses connected with the pier, the dredger, the infectious hospital, etc., he thought they should not incur further expenditure. He asked them to vote for his motion, as he believed the opinion of the majority of the ratepayers was against applying for a provisional order. The Mayor seconded the motion, but after a long discussion it was lost by 6 to 15.

Wilmslow.—On the recommendation of the Highway Committee, the Urban District Council have decided to oppose the application of the Alderley Edge and Wilmslow Electric Supply Company for a provisional order, and that the Council apply to the Board of Trade for a provisional order under the Electric Lighting Acts, 1882 to 1888, for supplying the district of Wilmslow with electric energy; that the clerk act as the Council's solicitor, and be instructed to prepare the application, plans, notices, and take all necessary steps for the purpose of the application, and engage a consulting electric engineer if required. Mr. Pearson said if they sanctioned the provisional order being proceeded with, it did not follow that they laid down the plant to work the district. He understood they were not going to put plant down until electricity could be produced at a considerably reduced cost.

National Telephone Company.—The directors have resolved, subject to final audit, to recommend at the forthcoming general meeting the following dividends for the half-year ending June 30 last: at the rate of 6 per cent. per annum, less income tax, on the amounts paid up on the first and second preference shares; at the rate of 5 per cent. per annum, less income tax, on the amounts paid up on the third preference shares; at the rate of 5 per cent. per annum, free of income tax, on the amounts paid up on the ordinary shares, being the same dividend as was paid in respect to the corresponding half-year of 1895, carrying the same amount to reserve—namely, £35,000—and about £17,000 forward, as against £3,907 last year. The transfer-books of the Company will be closed from the 17th inst. to 30th inst., both days inclusive, and the dividend warrants will be posted on the latter date.

Torpedo-Boat Destroyers.—H.M.S. "Swordfish," one of the torpedo-boat destroyers built by the Elswick firm and engined by C. E. Belliss and Co., Limited, of Birmingham, has passed with great success her dockyard official full-power trial at Chatham, the average power developed by the machinery being 4,359 i.h.p., or

Digitized by Google

about 10 per cent. above the contract. When it is borne in mind that the total weight of the engines and boilers only amounts to 56lb. per i.h.p. against 400lb. in the fastest Atlantic liners, the care required in designing and working with such reduced factors of safety as is necessary in these vessels will be better appreciated. The full run was made from the Maplin Sands towards Harwich and back, and concluded with circle turning at full and half power ahead and astern, and throughout the whole of the trial there was not the slightest hitch of any sort with the machinery and boilers.

Wrexham.—At the Rural District Council meeting a letter was read from the town clerk of Wrexham respecting the request of the District Council for an idea of how far they were going to apply for powers to supply electric light outside the borough, and which arose through the Wrexham Town Council asking whether the District Council had any objection to their proposed application to the Board of Trade for a provisional order to provide the borough and its immediate vicinity with electric light. The Town Clerk, in his reply, said that the area had not been definitely decided, but he thought that for the present a radius of two miles would be near the mark. Mr. E. S. Clark and Mr. Ellis said they had installations at their works, and both objected to Wrexham bringing their installations into their district. Mr. B Davies proposed that the matter be deferred until they had the definite area before them, and this was adopted.

Bristol.—The Electric Light Committee have decided to lay a main from White Ladies'-road through Cotham-hill, Woodland-road, to Highbury Chapel and University College-road. A Local Government Board enquiry is to be held into the committee's application to borrow £75,000. The Town Council have given permission to the National Telephone Company to lay pipes containing telephone wires on certain conditions under the following streets—viz., High-street, Baldwin-street, St. Augustine's-parade, Denmark street, Unity-street, Park-street, Queen's-road, Westbourne-place, and Oakfield-place; Bristol Bridge, Victoria street, Thomas-street, Portwall-lane, and Temple-gate; Bath street, Philip-street, Narrow Plain, and Broad Plain; Maryleport-street, Peter-street, Castle Mill-street, Broad Weir, and Narrow Weir; Merchant-street, Old King-street, Barrs-street, North street, King square-avenue, and Jamaica-street—and to construct manholes at various points in the footways.

Boston.—At the Town Council meeting, Alderman Simonds moved that the Paving and Lighting Committee be appointed to enquire into the advisability of erecting an electric light installation for the purpose of serving the lighting requirements of the town and dock. He stated that practical experience had taught him that the electric light was not only far superior, but was very much cheaper than gas. Peterborough, with a population of about 25,000, had recently applied for a provisional order to expend £20,000 in providing electric light, and Shrewsbury, with 25,000 inhabitants, had lately spent a similar amount in like works. He pointed out that the price of gas in Boston was very much higher than in other towns At Sheffield 2s. per 1,000ft. was charged, at Hull 1s. 10d, at Lincoln 2s. 6d., and at Grimsby 2s. 6d, but at Boston the price was 3s. 10d., with no reduction to the Corporation, who were the largest consumers. Alderman Weightman seconded the proposition, and it was carried.

Dorking.—A letter was read at the Urban District Council meeting from the Guildford Electricity Supply Company stating that application was intended to be made, on or before December 21 next, by a memorial to the Board of Trade for a provisional order, to be confirmed in Parliament in the ensuing session, whereby it was proposed to authorise the company to supply electricity for any public or private purpose within the area of the Dorking local authority. The Chairman suggested that they should again approach the Dorking Gas Company and see if they could not come to some understanding with regard to incandescent gas lighting. The Council now felt that some definite steps should be taken to get a better light in the streets than they had had lately. His own view was that if they were unable to come to any satisfactory arrangement with the gas company, they should turn their attention to the electric lighting companies Mr. Chalcraft proposed that the chairman's suggestion be adopted, which was seconded by Mr. Wood, and carried.

Newington.—The Vestry have decided "that Messrs. Kincaid, Waller, and Manville be engaged for a fee of 50 guineas to prepare a report dealing with the system of electrical distribution best adapted for Newington, the capacity of the station, the capital cost, the distributing mains, the revenue reasonably to be derived, the cost of maintenance, statistics from all municipal undertakings to date, and all necessary assistance in making a fresh application for a provisional order should the Vestry decide to apply to the Board of Trade for same; and in the event of such application being made, and a provisional order sanctioned by Parliament, such fee of 50 guineas to merge into the usual 5 per cent. for preparation of plans, specifications, and supervision of works to be carried out under the order, it being distinctly understood that the only extra fees payable in excess of the agreed fee will be in respect of attendances in the event of a local Board of Trade enquiry, and the ordinary out-of-pocket expenses for telegrams, cab fares, postage, and such like expenses."

Northwich.—At the meeting of the Urban Council a letter was read from Mr. E. T. Ward, secretary of the Northwich Electric Light Supply Company, giving notice on behalf of that company of their intention to forthwith apply to the Board of Trade for a provisional order authorising the company to supply electricity for public and private purposes within the area of the Urban Council of Northwich. The Clerk said it was advisable to report what position the Council was in with regard to the service of the notice. He found that by the Act of 1888 the consent of a local authority was generally necessary before the Board of Trade issued a provisional order. Such orders, it is stated, were not to be issued without the consent of the local authority of the district unless the Board of Trade, under special circumstances, considered that such consent ought to be dispensed with. As to monopoly, none was created by the issue of a provisional order or license under that Act, therefore the Council might take it for granted that before the Board of Trade issued an order it would communicate with the Council.

Bacup.—At the quarterly meeting of the co-operative store, the sub-committee on electric lighting presented their report, in which they said: "Whilst admitting the advantage of electric lighting in having less depreciation in drapery, boots, and shoes, as compared with gas, less risk of fire, less injury to the health of the employés, and a saving in painting, cleaning, etc., we are, however, of the opinion that we should not at the present time be justified in saddling the society with what might prove a serious burden. The cost of an installation complete would, in round figures, amount to £1,000, and in working out the annual cost we find it to be as follows: interest on £1,000 at 5 per cent., £50; depreciation at 10 per cent., £100; repairs and renewal, £10; waste oil and water, £20; engineer, £70—total £250. The amount paid for gas lighting is about £220 per year, and the cost of working the gas-engines to make the electric light would be about the same amount, so that for 10 years we should be taxed with an extra £250 per annum over and above the cost of lighting with gas as at present. After very careful consideration, we recommend that for the present we do not adopt electric lighting."

Exeter.—The following recommendations of the Special Committee on Electric Lighting have been adopted by the City Council: "That two electrical assistants be retained at the works, one at £60 and the other at £52, with an improver at £20; a first engine-driver at £2 a week, a second driver at £1. 4s, and a foreman of outside work at £2. 2s., their working hours to be 56 per week; that the surveyor be instructed to provide a new set of ropes and other apparatus, and that he be empowered to carry out on his own responsibility repairs costing not more than £50; that the price quoted for the lighting of the hospital be 6d. per Board of Trade unit, with a 25 per cent. discount if a *bonâ fide* all-night supply was taken, and additional specified discounts; that the light be offered to the Post Office on special terms; that a 300-i.h.p. boiler, feed pump, steam alternator, and sundry apparatus be provided for the station at a cost of £2,100; that sufficient length of cable be obtained to put High-street, a portion of Queen street, Fore-street, South-street, and part of Sidwell-street on the large transformer circuit, the new cables to be laid under the footways on both sides of the thoroughfares to avoid cross-street openings and risk of damage." The estimated cost of carrying out the last-named recommendation was £1,325.

Warrington.—The Town Council have confirmed the action of the General Purposes Committee in instructing the town clerk to oppose an application for power to supply electrical energy to Warrington which an electric lighting company intended to make to the Board of Trade. Councillor Bennett thought the opposition to the electric lighting company was only justified on the assumption that the Corporation intended to provide electrical facilities themselves. One or two local tradesmen had gone so far as to instal electricity in their own premises Councillor Roberts said it was not the intention of the General Purposes Committee to allow any outside authority to come there and obtain powers for providing the electric light which the Corporation would afterwards have to buy at an enormously increased value Councillor Heaton said the Gas Committee were, if they had applications from a certain number of the inhabitants of Warrington, prepared to deal with the electric light. If Mr. Bennett and half a dozen other people with some substance about them would apply, they would be able to put them in the light. Alderman Sutton thought Councillor Heaton was quite right in saying that the Gas Committee would be prepared to undertake to put in the electric light if they saw the necessity for it. At present he was quite satisfied it would not pay to proceed.

London Lighting Extensions.—The London County Council have granted applications from the following companies: the House-to-House Company to construct small transformer-boxes in connection with mains already laid, to lay high and low tension mains in part of Warwick-road and in Nevern-square, and to construct four transformer street boxes in connection therewith, and to lay low-tension mains in Courtfield-gardens; the County of London and Brush Provincial Electric Lighting Company of intention to construct a large transformer-box in Burston-road instead of in the position previously sanctioned at the corner of High-street, Putney; the Charing Cross and Strand Electricity Supply Corporation of intention to lay mains in the Strand from Bull-inn-court to Burleigh-street, in Garrick-street and Great Newport-street to the subway in Charing Cross-road, in Mercer-street, Castle-street, and Neal-street. The Highways Committee's report stated that it had been represented to them that it would be a convenience to the House-to-House Company if, instead of the one month's notice required by its respective orders to be given of new works, the Council would accept four days' notice with reference to the construction, in connection with mains already laid, of small transformer-boxes of the kind and size above specified. The committee saw no objection to this concession, which would, no doubt, facilitate the company's business, being made, and they recommended accordingly.

Hammersmith.—The Electric Lighting Committee reported at the Vestry meeting as follows: "That the engineer brought before us the advisability of the two large boilers to be supplied

Digitized by Google

under Messrs. Ferranti's contract being fitted with superheaters, at an additional cost of £270. Although these were not provided for in the original specification, the engineer now reports to us that, in his opinion, by the use of these superheaters there will be a great saving in the coal consumption, perhaps some 15 to 20 per cent., and as in all probability they would in a year or two have to be provided, we recommend that the Vestry, acting under the advice of the engineer, do sanction the extra expenditure on Messrs. Ferranti's contract." Mr. Searle moved the adoption of the report, and in answer to a member as to why it was that the advantage of superheaters had not been found out before, he replied that they were not included in the original specification because the experience had not been gained that they had at present. The results of the experiments had shown the great advantage that was to be gained by the use of these superheaters. The engineer was perfectly certain that they would be a great saving to the parish, not only in a less consumption of coal, but also in saving the machinery a great deal. The committee's report was adopted. The Finance Committee recommended the Vestry to apply to the London Council for their sanction to the borrowing by the Vestry and for the advance of £41,046 for the electric lighting and other purposes. This was agreed to.

Appointments Vacant.—The Commissioners of Sewers require a resident engineer to look after the Central London Railway works The appointment is a temporary one at £6 a week and application must be made to the clerk of the Commissioners before Monday.—The governing body of the Northampton Institute, Clerkenwell, E C., invite applications for three appointments. The first is for a head of the department of mechanical engineering and metal trades, salary £250 per annum; the second is for a head of the artistic crafts department, salary £250; and the third is for a chief assistant in the department of applied physics (including electrical engineering); salary £180 per annum. The appointments will date from October 1 next, and applications are to be sent in to the principal, Mr. R. Mullineux Walmsley, D.Sc., not later than 10 a.m. on Tuesday, July 28.—The Corporation of Londonderry invite applications for the post of dynamo attendant, which are to be sent in to Mr. R. P. Chambers, town clerk, not later than Monday, 27th inst.—The Plymouth Corporation invite applications for the post of draughtsman and assistant to the borough electrical engineer. Applicants must be over 25 years of age. The person appointed will be required to devote his whole time to the service of the Corporation. Salary £150 per annum, rising by annual increments of £10 to £200. Applications, accompanied by copies of not more than three testimonials, and endorsed "Assistant Electrical Engineer," must be delivered to Mr. J. H Ellis, town clerk, not later than Thursday, the 30th inst. Further particulars of these appointments can be seen in our advertisement columns.

Wolverhampton.—The Lighting Committee have presented their report on the working of the undertaking to the Council. The report states: "Your committee have delayed presenting the accounts of the year ended March 31, 1895, until the accounts for the year 1896 were completed, as at the former date the supply of electricity for public lighting and private purposes had only been in progress for two months, and the accounts for so short a period would have been of little value to the Council, and no guide as to the results of the undertaking from a commercial point of view. The operations of the year ended March 31, 1895, resulted in an adverse balance of £1,162. 4s. 9d., but it must be pointed out that the accounts for this period were debited with interest on capital, and also with a sum of £868 3s. 6d., representing one year's instalment to the sinking fund in respect of capital, whilst the receipts for electricity supplied only extended over a period of two months. As regards the accounts for the ended March 31, 1896, the revenue account shows a credit balance of £1,570. 2s. 8d., which represents 4·85 per cent. on the borrowed capital. The expenditure in respect of interest on capital and contributions to the loans fund sinking fund amounted to £1,811. 7s. 2d. The loss for the year has therefore been £241. 4s. 6d., as shown on the net revenue account. Your committee view these results with satisfaction, and have no hesitation in saying that the undertaking will, in due course, prove a source of profit to the Corporation. It is proposed to carry the balance forward, and to meet the same out of future profits of the undertaking, so that there will be no necessity to ask for a rate in aid."

Hampstead.—The report of the Lighting Committee at the meeting of the Vestry recommended that additional high-tension feeders be laid down from the central station to a number of sub-stations at an estimated cost of £787. 14s. 2d. for cable, and that a supplemental water supply be provided to the station by means of a 4in. supply main from the bottom of Arkwright-road at an estimated cost of £155. This was adopted. The same committee reported that they had instructed the engineer to adapt one of the existing street gas lamps for incandescent electric lighting and try the same as an experiment; that they had instructed the engineer to try the effect of using Welsh coal at the station for a period of 14 days; that they had empowered the engineer to procure a coal-weighing machine at an estimated cost of £10; and that they had given instructions for a clerk of works for the extension of the central station to be appointed, and had left the selection to the chairman of the committee and the architect. This was approved Mr. E S. Payne moved, "That it be referred to the Lighting Committee to report as to the cost of lighting by electric arc lamps the High-street and parts of Rosslyn-hill and Heath street and to bring up a recommendation thereon " He remarked that of recent years the arc lamps had been very considerably improved, and many of the trading centres of the Metropolis were being lighted by means of arc lights. Islington was doing it, St. Pancras had done it, and he thought Hampstead should do it. Mr. Greenhill said he did not object to the motion, but thought that the reference should extend to the whole of Haverstock-hill. Mr. C. H. Reed, chairman of the Lighting Committee, said that the committee had the whole subject under consideration, but had deferred their report until after the summer vacation. The Chairman said that, this being so, the motion and amendment were both out of order, and the discussion therefore ended.

Whitehaven.—Councillor Musgrave, in moving the adoption of the Lighting Committee's minutes at the Town Council meeting, said it must be satisfactory to know that their faultage had been satisfactorily reduced. On the subject of the Siemens's contract and the point in dispute, Dr. Hopkinson had arrived at the conclusion that in regard to the relaying of the substituted main conductors by the contractors, the Council should be at the expense of opening the trenches. The committee, however, were unanimous in considering this a wrong view of their contract with Messrs. Siemens. But the engineer had the matter in hand, and he, in his wisdom, had given a certificate that they were to be at the expense of opening the trenches. The town clerk was of a different opinion, and the committee did not arrive at his view without making an effort to put the matter right. At the present time they had expended £205 of the ratepayers' money in wages in opening the trenches, and they must be aware that there was a great deal of work to be done before the whole of the cables could be relaid. They considered when they opened up the trenches in the first instance at their own expense to receive the cables that they honourably performed their part of the contract. That was the position of the committee, and they maintained that Messrs. Siemens and Co. had adopted that view, because the firm in cases where there had been failures in different parts had asked them to open the trenches, and had actually already paid them for doing so in every instance So that it was practically an admission that the contention of the committee was a correct one. Councillor Barr seconded. Councillor Dickinson wanted to know if the Council were not more to blame than the contractor. This at least was his opinion. He further desired to know if, when the wire was first put in, an inspector was appointed, because he could never ascertain the fact. The Deputy-Mayor: The work was certainly inspected as it was done Councillor Dickinson said that as regarded the action of the Council, he held that they had made a mess in taking the work into their own hands. The contractor should have been allowed to complete his own work. The minutes were adopted.

The Blackwall Tunnel.—The following report from the Bridges Committee was presented at the last meeting of the London County Council: "We have to report that for some months past we have been considering the question of lighting the Blackwall Tunnel, and that we have come to the decision, after inspecting the tunnel, that electricity is the best and cheapest form of lighting. The continuous requisition of the light both day and night will require a uniform supply which will greatly decrease the cost per unit The cost will reach £25,000, which includes buildings, subway, plant, mains, and lamps for the light at 10ft. centres, and will be paid out of the £50,000 provision money which has been set apart for work of this description. We have given directions for the buildings for the generation of the electricity to be erected on Northumberland Wharf, Poplar, as it is the most convenient site for the purpose and have agreed to use No. 2 shaft on the wharf for tunnel purposes only. With regard to the prices for the buildings, we have arranged with Messrs. Pearson and Son, the contractors, such terms as we think are favourable to the Council. With regard to the plant and machinery, the specification is well in hand, and the necessary drawings are being prepared, and we anticipate that the working of the installation, exclusive of depreciation, repairs, and capital charges, but including lamp renewals, will be about £5,000 a year. We have arranged for three lines of lights in the tunnel, and each line to be controlled independently at the engine-room switchboard. The surface and sunk approaches will have a line of lights on each side as in ordinary street-lighting; this will reduce the attendance for lighting and extinguishing the lamps to a minimum. With regard to obtaining the plant, we are of opinion that the best course to take is to obtain tenders from a few selected firms, as it is necessary that the plant to be supplied should be of the highest excellence. As the Council is about to adjourn for the summer vacation, and as the work must be proceeded with without delay, we recommend that the Bridges Committee be authorised to invite and accept tenders for the plant required in connection with the lighting of the Blackwall Tunnel, and that the operation of standing order No. 178 be suspended accordingly."

Torquay.—Colonel Durnford, R E., has held an enquiry on behalf of the Local Government Board concerning the Town Council's application for leave to borrow £23,000 for electric lighting works. Mr. Percy Pearce said the provisional order sanctioning the supply of electricity was obtained in 1891. It would be unwise and foolish of the Council to delegate their powers to a private company. No less than 51 corporations were already supplying electricity, and 25 corporations were about to start supplies. There were innumerable private companies who were seeking for the powers of the Council in the matter. That was one of the strongest possible arguments for the position taken up by the Council, because private firms would not be so anxious to take up the scheme if it would not be a financial success. There had been only four boroughs who had undertaken electric lighting and had parted with their schemes to companies, and at least two of them had reason to regret their folly. At Cambridge and Dover (two of the towns alluded to) the companies were making large profits. He believed the growth of the demand in Torquay would be as great as in other towns. There was abundant justification for that, seeing that Torquay was so frequented in winter.

Digitized by Google

They had exceptional facilities for supplying the light, seeing that the building was provided. The Town Clerk said they had been continually receiving applications from private companies who were seeking to exercise the powers of the Corporation in the matter. The Guildford Electricity Supply Company had given notice of application for a provisional order, and a firm of electrical engineers at Taunton had asked the Council what they intended to do, as residents at Torquay had consulted them with a view to putting in electric plant. A canvass of traders was made concerning the taking in of the light with most encouraging results. Mr. W. H. Trentham, M.I M E, said that he had had 20 years' experience as an electrical engineer. There could be no doubt that the high-tension system was most suitable for Torquay, partly on account of the extreme length of the compulsory area, also on account of the character of the Lincombe and Warberry districts. The houses being so far apart rendered the cost of low-tension mains out of all proportion to the revenue to be derived therefrom. He estimated the cost of the plant for 4,000 16 c.p. lamps and 70 arc lamps at £22,000. The revenue per annum, charging the current at 6d. per unit, and taking the consumption at the very moderate rate of 13 units per 30-watt or 8-c p lamp, would amount to £4,322, or, adding £519, the cost of gas lamps in roads and pier. the total revenue, with £150 for meter rents, would be £4,991. The cost of electricity at 6d. per unit was approximately the same as gas at 4s. 5d. per 1,000ft., but in actual practice it was found equal to gas at 3s. per 1,000. Other evidence was taken and the enquiry terminated.

PROVISIONAL PATENTS, 1896.

JULY 6.

14946. Improvements in insulating electric conductors. Willoughby Statham Smith and William Puddicombe Granville, 24, Southampton buildings, Chancery-lane, London

JULY 7.

14993. The external walls telephonic connection. Frederick Jones, 76, Wakehurst road, Clapham Junction, London.

14996. Improvements in and connected with automatic or thermostatic fire-alarm telegraph systems. William Edwin Heys, 70, Market-street, Manchester (Joseph W. Frost, United States.) (Complete specification.)

15006. Improvements in phonographs. Paul Constant Amans, 8, Rue des Princes, Brussels.

15013. Improvements in electrical selectors and answer-backs. Theodore McKenna, 17, Basinghall street, London (John Mowe Drysdale, United States.) (Complete specification.)

15031. Improvements in dynamo-electric machines and methods of compounding the same. The British Thomson-Houston Company, Limited 70, Chancery-lane, London. (Charles P. Steinmetz, United States.) (Complete specification.)

15072. Improvements in or relating to phonographs. Horatio John Heinze 111, Hatton garden, London.

15074. Improvements in or relating to electrically-ignited torches, cigar lighters, or the like. John Hencken and John Henry Meyer, 111, Hatton-garden, London. (Complete specification.)

15078. Method of and means for recording in connection with electricity supply. Arthur Marston Billington, 46 Lincoln's-inn-fields, London.

JULY 8.

15102. Improvements in the method of winding armatures for multipolar continuous-current dynamo-electric machines and electromotors. Frederick Henry Royce and Ernest Alexander Claremont, 53, Arcade-chambers, St. Mary's gate, Manchester. (Complete specification.)

15129. A process and apparatus for effecting electrolysis. Frederick William Golby, 36, Chancery-lane, London. (Otto Arlt, Germany.) (Complete specification.)

15162. Improvements in electric meters. Siemens Bros. and Co , Limited, 28, Southampton-buildings, Chancery lane, London. (Siemens and Halske Germany.)

15176. Improvements in or connected with dynamo-electric machines for use in what is known as the three-wire system. James Yate Johnson, 47, Lincoln's-inn fields, London. (The Elektricitäts Aktien Gesellschaft vormals W. Lahmeyer und Co., Germany.)

JULY 9.

15223. Improvements in or relating to the production of electricity. Hugh Fitzalis Kirkpatrick-Picard, 111, Hatton-garden, London.

JULY 10.

15292. Improvements in arc lamps. Annie Taylor Schmidt and Frederick Thomas Schmidt, 12, Cherry-street, Birmingham.

15303. Improvements in the method of and means for protecting electric lamp fittings from damp and corrosion and for preventing short-circuiting. Joseph Lomax Kendal, 5, John Dalton-street, Manchester.

15318. Improvements in apparatus for the ignition of hydrocarbon and other gases by electricity. Max Byng and Leopold Dowland Cole, 73, St. Stephen's-road, Upton Park, London.

15321. Automatic switch for sending the current always in the same direction through the whole or some part of the circuit independent of the current in the main. William Booth, 98, Clerkenwell road, London.

15322. Converter for changing continuous into alternating current to be used in connection with transformers. William Booth 98, Clerkenwell-road, London

15326. Improvements in insulating and supporting electric wires intended to act as electrical resistances applicable as radiators of heat for cooking, warming, and other purposes. Rookes Evelyn Bell Crompton and Edmnd John Fox, 55, Chancery-lane, London.

JULY 11.

15380. Improvements in the means of connecting branch electric light wires to the main or line wires. Samuel Scargill and Albert Hanson, 2, Market street, Bradford.

15433. An improved preparation of electrolyte for use in semi-dry primary or secondary electric batteries. Henry Weymersch and Arthur McKenzie Cardwell, 47, Lincoln's inn fields, London.

SPECIFICATIONS PUBLISHED.

1895.

11708. Electric switch apparatus. Pippette.

12042. Globes for arc lights, etc. Jandus.

13091. Electric switches. De Ferranti.

14066. Dynamos and electromotors. Parsons.

14739. Incandescent electric lampholders. Huisman and Gover.

14902. Secondary battery plates. Fabbro.

15260. Electromagnetic separators. Robinson

15338. Arc lamps. Barnett.

15442. Suspending electroliers, etc. Faraday.

15450. Electric telegraphs. Roos and others.

NOTES.

Spanish Cables.—The steamer "Dacia" has recovered and spliced the broken cable from Cadiz to the Canary Islands. The Ceuta cable has been repaired same time.

Steam-Engine Efficiency.—Prof. D. S. Capper and Mr. Henry Davey have been added to the committee appointed by the Institution of Civil Engineers to consider the question of a standard or standards of thermal efficiency for steam-engines.

British Institute of Public Health.—Yesterday (Thursday) was the opening day of the congress of the British Institute of Public Health at Glasgow. The inaugural address is delivered by the Lord Provost (Sir James Bell), and Prof. Ramsay, F.R.S., delivers an address as president of the chemistry and engineering section.

The Electrophone.—By way of an experiment, Dr. Jameson's trial has been laid on by the Electrophone Company to their offices in Gerrard-street, W. It may some day be an interesting point for the lawyers whether a person is to be considered legally as having heard a witness's statement in court when he was really a mile or two away at the time.

Telegrams in Italy.—According to the official returns of the Italian Ministry of Posts and Telegraphs, the number of messages sent over the wires during the last half-year of 1895 was 22,002,206. This includes despatches on the Red Sea line (Massowa and Assab). The revenue was about £27,500, no allowance being made for Government or service messages.

Society of Chemical Industry.—The annual London meeting of the members of the Society of Chemical Industry was brought to a close last Friday. During the day visits were paid to the Royal Arsenal, Woolwich, the ordnance factories, and the electrical and telegraph cable works of Messrs. Siemens Bros. at Charlton, and in the evening the members and a number of other gentlemen dined together at the Hotel Cecil. Mr. Thomas Tyrer (president) occupied the chair.

Motors for Printing Work.—In reference to employment of electromotors supplied by the town mains for the purpose of working printing presses, which has been mentioned elsewhere in this journal, it may be worth notice that at the last meeting of the Swansea Town Council an application to take two wires across High-street was made on behalf of Mr. J. C. Howell, it being stated that the object was to make experiments in driving the machinery at the office of the *Daily Post* by means of current from the electric lighting station in the Arcade. Permission was granted for three months.

Magazine.—We have had forwarded to us the August number of the *English Illustrated Magazine*, naturally looked to find if it contained something relating specially to electrical work—not with any great success. Mr. Marquardt, one of the survivors, contributes an account of the loss of the "Drummond Castle." Though the smashing of the ship on the rocks stopped the big engines at once, the electric lighting plant ran on to the last. "The bow sank and put out the fires; the electric lights suddenly blinked out. Immediately after, I found myself in the water, the ship having slipped off into the water right beneath me." The magazine seems a decidedly good sixpennyworth.

Tramcar Fenders.—The City Council of Oakland, California, have demanded that every street-car company in the city shall properly equip its cars with fenders, and they intend to enforce the demand. An ordinance has stood on the statute-books of the city for years past requiring that all street-cars should have life-saving fenders attached, of a pattern that should satisfy the Council; but, like a good many other ordinances, no one took any notice of it, till car ran over a few children and killed them. Several of the car companies have submitted plans of fenders, but the design which seems to meet with most satisfaction is that already in use on the Oakland, Alamada, and Piedmont Electric Railway, and which is the invention of a Mr. Clarke, of Alamada.

The Telegraph Congress.—As a result of the International Telegraph Congress at Budapest the new clauses are to be added to the international telegraph statutes, to the effect that the senders of telegrams to unknown addresses shall be informed that the addressee cannot be found. If the receiver of a telegram with answer prepaid does not send a reply the original sender can claim within three months the amount paid for an answer, and information respecting the delivery of a telegram, which hitherto has only been given by wire, may be furnished to the sender through the less expensive channel of the post, and, lastly, telegrams, if desired, will be sent after the receiver, in the case of a new address, in the same way as letters. The congress closed on Tuesday.

Labour Troubles.—A strike has been started at Messrs. Thorneycroft's works at Chiswick owing to the Boilermakers' and Iron Shipbuilders' Union and the Amalgamated Engineers being unable to agree whether a rivetter of iron plates or a fitter is the proper man to do tube work on water-tube boilers. As the fitters would go on strike if the boilermakers did the work, and the boilermakers would go on strike if the fitters did the work, and as both would strike if anyone else did the work, there is no other prospect than that work will be stopped indefinitely, as it is practically impossible to carry on the work of the yard and shops without members of both unions. Meanwhile, it is stated, there are contracts pending with penalties for delay. Though these are often covered by strike clauses it is not always so, and foreign purchasers especially are getting every year more shy of admitting the strike clause in English contracts. Looked at from their point of view it is not surprising.

Central Technical College.—The diploma of associate of the City and Guilds of London Institute has been conferred on the following matriculated students who have this year successfully completed a full course of instruction at the City and Guilds Central Technical College: civil and mechanical engineering—W. Gore (Siemens medal), V. Cooper, A. M. MacColl, J. S. Wilson, B. Price, D. H. Bayley, R. F. Baker, I. Barry, M. G. Weekes, C. E. H. Salmon, L. Temple, D. J. Jaffe, H. J. Saunders, H. M. Kirkby, J. A. Jones, A. Kenrick, A. B. Buckley, G. S. Perry, G. P. Mair; applied physics and electrical engineering—E. Ray (Siemens medal), C. A. Taylor, I. Braby, G. A. Maquay, G. W. D. Ricks, P. A. Tucker, E. Morgan, Y. V. E. Watlington, C. Barber, P. F. Rigden, J. F. Collard, W. Phillips, J. F. Pringle, C. E. Vance, H. J. Gridley, H. F. Hesse, M. J. Scears, W. F. Daniel, W. Steuart; applied chemistry—T. M. Lowry, E. F. Renwick, T. H. Pope, W. S. Gilles, A. J. Shelton, N. F. Deerr, H. C. Sayer, S. G. S. Panisset.

Motors in the Dairy.—The Devonshire people are reported to have invented the idea of heating the milk to make the cream rise — hence that interesting native product, clotted cream. Nowadays centrifugal separators are used, and Mr. T. R. F. Bolitho, of Trengwainton, near Penzance, having indulged in a model dairy, has naturally put one of these down, and has added

Digitized by Google

a *délaiteuse*. Possibly even English dairymen may require to be told that this is a machine for separating the buttermilk from the butter while the latter is still in the granular state. It is so far like the separator that it involves the centrifugal principle. To work these and other dairy machinery, Mr. Bolitho uses an electromotor driven by accumulators. Details are wanting, but it may be said that an electromotor direct-coupled would be an ideal mode of running a separator if current were obtainable on a farm. Usually it is not, and unless there are exceptional facilities for charging it is to be feared that the expense of the accumulators will more than counterbalance the advantages. But it must be remembered that the only other alternative is to get up steam twice a day to do, perhaps, less than half an hour's work—which is not economical—or to use horse gear, which is even worse.

Lamp Accidents.—Sir Arthur Arnold, the chairman of the London County Council, in his speech on Tuesday last, in which he reviewed the work accomplished by the County Council during the past year, devoted a good deal of attention to the fire brigade department. The expenditure in this department increased by £23,000 in the past year, and he estimates that it will continue to rise till the annual expenditure reaches about £200,000. A melancholy item noted in his speech was the fact that some 450 fires were caused by lamp explosions in the year, and that 45 people lost their lives in consequence. These totals in London only might make one wonder that the fire insurance companies do not take some action in the matter, particularly when one remembers their requirements in the subject of electric lighting. The Petroleum Committee held its last sitting for this session on Wednesday, when Mr. Paul Babcock, a director of the Standard Oil Company of the United States, gave evidence. Mr. Babcock said that illuminating oil was supplied to Germany, Holland, Belgium, Italy, China, Japan, Java, and South America which gave a lower flash-point than the oil supplied for the English market. In his opinion, if England were by legislation to raise the flash-point to 90deg., and the rest of the world were to follow her example, there would soon be an oil famine. There were comparatively few lamp accidents in America; but then the people there were very careful about their lamps, and would never think of using some of the English lamps.

The Metric System.—In the House of Commons Sir S. Northcote has asked the President of the Board of Trade if he would introduce this session a Bill to deal with the metric system, in order that chambers of commerce and other parties interested might have sufficient time during the recess to consider the proposals of her Majesty's Government on the subject, and Mr. Ritchie replied that he would be glad to introduce a Bill; but, of course, not with any intention of proceeding with it this session. The chambers of commerce no doubt know what they want, but the particular advantage of this course of proceeding does not appear very evident to an outsider. The joint authority of Mr. Herbert Spencer and the *Times* have given pause to a great many people who before were quite ready to let the change go forward. The advocates of the metric system would stand a much greater chance of success if they would agree upon the way in which the change should be effected, and settle such practical points as whether we are to adopt the system, names and all—in which case people will continue to think in yards and tons—or whether English names are to be taken whenever there is a measure that can be made to fit with a little stretching. Whether or not we shall ultimately be forced into the use of the metric system by the practice of the rest of the world may very reasonably be questioned, but this time the movement will come to nothing, except perhaps a permissive use—*i.e.*, a permission which no one will avail himself of. The pity of it is that we did not rationalise our own system while there was yet time.

Electric Trams and Electrolysis.—In the *Street Railway Journal* there is given an account of how a waterworks company in the United States got as far as an action for damages by electrolysis, and found they were wrong after all. It appears that in Omaha the Farmers' Loan and Trust Company, which had the waterworks in hand, became alarmed by the reports of certain experts regarding the effect of electrolysis on the pipes, and probably honestly believed that they were badly damaged. Suit was brought for 250,000dol. It was not an easy matter to prove absolutely to the contrary, as the pipes were all buried, and the particular point near one of the power-houses, which had not been properly connected, showed damage for a block or more from electrolysis, and had to be relaid, making it look, of course, as if the trouble might soon extend over a large territory. But by great good luck it happened that in compromising some other matters with the city and insurance people, the waterworks company agreed to relay with larger pipe nearly all its mains in the business part of the city. This was all done last year, and, of course, the uncovering of the pipes in all that district which was thickly covered with street railway lines was watched with intense interest by all parties concerned. Experts from both sides were constantly on hand. The result was satisfactory to everybody, as it was clearly developed that there was no electrolytic action except at one or two spots, and even there it was doubtful whether it was electrolysis. It was but natural when the waterworks people found that they had practically no grounds for damages that they should ask to have the suit dismissed, as they probably felt that the slight injuries they had sustained could be adjusted without recourse to the courts. This is the first action that has ever been brought in the United States on this ground, and our contemporary naturally congratulates the electrical industry on the result.

Telephones in Russia.—It has been determined that the telephone line which was put up between St. Petersburg and Moscow on the occasion of the recent coronation festivities shall be allowed to remain, and shall be available for use by the general public. On the subject of the development of telephonic communication in Russia, the *St. Petersburger Zeitung* says that the introduction of the telephone exchange system dates from 1882, when concessions were granted to a company for the establishment of telephonic systems in St. Petersburg, Moscow, Warsaw, Odessa, and Riga. There were several concessions to companies or private undertakers in the succeeding years, and in 1884 the first Government system was established at Kief, though there had been previous installations in connection with the St. Petersburg palaces. After that progress was rapid, so that by 1895 41 additional town systems had been established, and at present all the larger towns of the empire are provided with a properly-equipped exchange As to subscribers, the list is naturally headed by St. Petersburg, with 2,230 in July, 1895; but as the number the year before was 1,977, there has probably been a considerable increase by this time. Such places as Baku and Nishgorod have 502 and 367 subscribers; the smallest is Berdiansk, with 30 only. The aggregate for the empire was, in 1895, 9,007 subscribers on companies' and 6,111 on Government systems, while the corresponding figures for the previous year were 8,004 and 3,958. This shows a considerable augmentation, and there has been a corresponding increase in the length of lines during

Digitized by Google

the year. Trunk-line work is naturally more backward, since the distances in Russia are so much greater than in other European countries. The trunk lines between Rostoff and Taganrog and Odessa and Nicolaieff may be mentioned. Besides all that have been referred to above, there are, of course, a quantity of purely private telephone installations serving factories and so on, but not connected with any central exchange.

Motorcarts.—Cyclists say that the cabbies make a dead set at them, so it is not altogether surprising to hear of hostilities against motorcarts. Last week, John Harlow, a Margate cabman, was charged before the local magistrates with attempting to damage a motorcar and endangering the lives of the passengers. Mr. Alfred Cornell, the owner of the car, said that the defendant overtook him, whipped his horse furiously, and tried to pull it on to the car, but the animal backed away from it. He got into a place of safety, but for half an hour the cabman drove to and fro trying to get at him and threatening him. Defendant said he merely put up his hand for the car to stop, as his horse was frightened. This seems considerably to exceed the usual conflict of evidence in a running-down case, but as the magistrates imposed a fine of 26s., it is to be presumed that they did not believe the cabman. The motorcart is illegal at present, but it has its rights, and must not be smashed at sight. The Britannia Motor Carriage Company has held its statutory meeting, and the chairman has explained the reasonableness of giving the weight of the motor and omitting to say anything of the battery necessary to drive it. Sanguine views appear to be professed on that Board as to the technical knowledge of the average investor and his ability to draw inferences. An admirer of the Britannia motorcart who has seen it says there is "no smell of oil or steam or heat, and it does not in any way resemble a traction engine or an animated bathing machine." The inference is somewhat unkind to the other motorcarts at the Imperial Institute. The mention at the meeting of primary batteries as a source of power does not impress us favourably. We should advise the shareholders to have the motor they have bought unseen inspected by some independent expert before the capital subscribed has been spent. Lastly, Messrs. McDonald Bros., of Strathsay, are reported to have a motorcart which is to weigh 3cwt. complete, including the batteries. The motor is a ¾-h.p. one, and worm gearing is used. When it comes to pass that every town in the kingdom has a public electricity supply on the continuous-current system, and you can get your accumulator charged as easily as you can bait your horse, there will doubtless be a great future for the battery-cart.

Wave-Forms.—The New York *Electrical World*, which has reprinted in full Messrs. Beeton, Taylor, and Barr's Institution paper on the influence of the shape of applied potential-difference waves on the iron losses of transformers, says that the conclusions which it contains are important from a theoretical as well as practical standpoint. Our contemporary considers the paper most interesting on account of the method adopted of altering the form of the applied potential-difference wave by injecting at definite intervals a capacity or resistance. As to the effect of higher harmonics having various phase relations with the fundamental, while the resultants may have the same effective value and yet have areas differing by several per cent., it is doubtful whether the case of depressed waves deserves more than a theoretical consideration, inasmuch as such curves are not likely to be produced in self-inductive circuits without capacity. If the latter be present, it is considered that it remains undisputed that condensers work most effectively when supplied with either rounded or sine waves of applied potential difference. The higher efficiency obtained by the peaked form has been plausibly explained by Dr. Bell, by stating that the effect of superimposing upper harmonics is equivalent to increasing the frequency. Variable conditions of load may produce sufficient differences in the shape of the E.M.F. waves to make it practically impossible to predetermine the most effective form of wave which an alternator should produce, and for this reason laboratory results have a limited value when their application in commercial practice is considered. After comparing the advantages of peaked and rounded waves, it is concluded that as to the merits of the two types of waves, only specific cases can decide. The advantages which might be gained by the use of peaked waves in ordinary commercial alternating-current supply, although considerable, are of doubtful attainment, and our contemporary is quite of opinion that no great efforts will be made on the part of manufacturers to determine the best form of peaked E.M.F. which an alternator should have in order that it may apply more satisfactorily than the existing types to the conditions presented in widely differing cases. If that is so, then it seems to us all the more reason why every encouragement should be given to the undertaking of any work that may help to determine it in the laboratories of technical institutes or elsewhere. Even if no results capable of immediate utilisation are obtained, such work is always valuable in one way or another.

Accident.—Last week an accident happened at the City of London Company's City station which resulted in the death of a foreman named John Jackson Chisholme. From the proceedings at the inquest held by Mr. Langham, the City coroner, it appears that Chisholme was helping Mr. William Parry, chief tester at the company's works. Parry had instructions to make St. James's-square station "alive" from Crosby-square and to shut down St. James's-square main. The test that he and the deceased were making was with a Silvertown portable testing set, and the object was to enquire into the condition of the main before making it "alive." The deceased had taken the inner conductor or cable out of its terminus once without any accident, but he was repeating the operation when he suddenly shouted, and it was seen that he had received a shock. He was in a half-stooping position, but in answer to another assistant, who enquired if he was all right, he replied, "Yes, I think so." A second or two later, however, he fell back, struggled, and died. Chisholme was standing on an indiarubber mat at the time, but was not wearing indiarubber gloves, although these were provided. In reply to Major Cardew, who was present at the inquest, it was stated that if the deceased touched the "live" terminal it would mean a 2,000 volts shock. Another witness, Horace Howe, an assistant tester, said he was present when the accident occurred, and gave it as his opinion that the deceased fell, and to save himself placed one hand on the wall and the other on the inner terminal. He might have fainted or have been reaching his gloves, which were just above him. Mr. F. B. Aspinal, superintendent of the works, could only account for the fatality by the supposition that Chisholme touched the terminal and received a shock through not wearing gloves. Mr. Aspinal produced a set of rules which forbade high-tension switches, fuses, or cable ends in the transformer station to be touched or interfered with in any way whilst they were "alive." This was signed by the deceased as well as the other workmen. Mr. Aspinal also said he considered that a shock of 900 volts was sufficient to cause death. Less had been known to do it, and very much more had failed. Dr. F. Clark having given evidence, the coroner summed

Digitized by Google

up, and the jury returned a verdict of "Accidental Death," adding a rider that the notice as to wearing gloves should be more extensively distributed at the works. This was not, however, the end of the matter, for the deceased's uncle got up in the court and made a statement as to certain remarks made by Chisholme, not to him, but to his wife. These amounted to the fact that the deceased had been apprehensive of neglect at the St. James's-square station, which would occasion danger to him. Upon this, the coroner allowed the verdict to be withdrawn and the inquest adjourned for further enquiry.

Electric Ploughs.—An illustration of Mr. Israel Hogeland's plough, to which reference has already been made in these columns, is given in the *Western Electrician* (Chicago) of July 4. The illustration is a process reproduction from a photograph, but, apart from the details of the motor and gearing, it is quite possible to form a fair idea of the machine. There are two shares of a nondescript shape and attached in a most primitive manner to the body of the machine, and no coulters whatever. In the illustration only one of the shares appears to be in use. Of course it depends on the depth of the furrow and the state of the ground, but this would agree with the statement that a 5-h.p. motor is used. The most striking thing, however, about the plough is the wheels. These are open ironwork constructions looking more like a river steamer's paddle wheels with rather short floats than anything else in the world. The object of these, of course, is to get a sufficient grip of the soil to overcome the resistance of the ploughshare. One of these wheels runs on the hard and the other on the already ploughed land, and must necessarily go over it more than once. What a "stetch' of stiff Essex wheat land would look like after Mr. Hogeland's plough had been over it must be left to the imagination. Probably the plough would not go, and certainly if it did it would carry a great deal of the land with it. At present, in steam ploughing the plough is strung on a wire rope, and hauled across the field and back by two engines. The friction and waste of power is enormous, and the wear of the rope and the cost of replacing it very heavy. Nevertheless, a certain amount of work is done that way on the contract system. If one engine only is used, the rope must go all round the field, with still more loss of power, and a complicated arrangement of "anchors" is necessary to take the strain at the corners. What is wanted is an arrangement by which the rope should remain still and the plough pull itself along it. The theoretical economy of this is evident, and experiments made many years ago showed that something a great deal more like an adequate return for the power expended could be obtained that way than is possible on the existing system. It remained only to construct a steam-engine of sufficiently light build to be able to run across a field without rendering it unploughable. The system was fully worked out, but was never carried into practice because the condition of agriculture did not appear to warrant the expenditure of the capital necessary. It would be an obvious improvement to keep the engine still as well as the rope, and the only practical way of doing this would be to carry the necessary energy to the plough electrically by means of a dynamo, conductor, and motor. On the other hand, the plough has simply been developed because horses and oxen cannot be taught to dig. A machine can be made to dig, and a digger does not require a rope to pull against. Moreover, digged land is better than ploughed land. The difficulty up to the present has been taking a heavy engine on to the land to work the digger. A comparatively light electromotor would be free from this objection. In one of these two ways the problem of mechanical cultivation will be probably solved some day. At present, however, it is doubtful whether either in Europe or America the situation is ripe for its introduction.

Isle of Man Tramways.—The opening of the Douglas Southern Electric Tramway took place on Thursday last week, and was favoured by magnificent summer weather, and large crowds assembled on Douglas Head to witness the inauguration. It was expected that the Mayor of Douglas (Major Stephen) would have performed the opening ceremony, but that gentleman was suddenly called away from the island, and his place was taken by Mr. G. W. Lowcock, the managing director. Before the trial trip was made the directors entertained a large number of guests at luncheon in the Villiers Hotel, Mr. W. P. Fawcus, one of the directors, presiding. Subsequently, the company were conveyed on beautifully equipped electric cars from Douglas Head to a point close to Port Soderick, the journey being accomplished to the entire satisfaction of the experts and visitors. On the return a stop was made at the power-house at Pigeon Stream, which the company inspected. The terminus at the Douglas end is under Douglas Head Hotel, but it is probable that in the near future the line will be extended to a point much nearer the town. The line is intended to open out the fine cliff and marine views of the isle, and the road is for the most part cut off the face of the cliffs, and follows the coast line from Douglas Head to Port Soderick. The length of the line at present constructed is 2¾ miles. The gauge is the normal 4ft. 8½in. of the English railways. The rails are of steel, 65lb. to the yard. The sleepers are also of steel, and, with the fastenings, weigh 55lb. each. All the ends of the rails at the joints have been connected with Chicago rail bonds. At present the line is a single one, with eight passing places. One of the features of the line is that there is hardly any straight piece in it, the route curving in and out as it passes through and over the headlands. There is not a level spot on the whole road, but the worst gradient is only 1 in 16. There are three bridges of 120ft., 240ft., and 110ft. in length respectively. The line is worked on the overhead system. The trolley wires are carried on steel poles with brackets, and a feeder runs on the poles for a distance of 1¾ miles. There are two trolley wires, one for the up and one for the down traffic, to simplify the arrangements at the passing places. The trolley wires are divided into half-mile sections, with a switch to each section pole, so that part of the line can be off if necessary. The generating station is at the Pigeon House Stream, and the plant is in duplicate, so that in the event of one engine breaking down there will be a second to fall back upon The rolling-stock, when completed, will consist of 12 cars and trailers. The cars already on the line are very like the cars which run between Ball's Bridge and Dalkey on the Dublin line. The work of constructing the line was carried out by Mr. H. L. Fletcher, resident engineer, and Mr. G. C. Pritt, assistant electrical engineer. Mr. J. J. MacMahon had charge of the overhead construction, and Mr. J. E. Winslow was chief engineer. The General Traction Company, Limited, are responsible for the work.

Electric Lighting in Odessa.—In an article on the progress of electric installations in Odessa the *Elektritschestwo* remarks that the development of electric lighting in that city dates from the year 1887. In that year the town theatre was built, and the authorities stipulated that it should be supplied with the electric light. The result was the erection of the first Odessa municipal generating station, containing two Ganz dynamos, supplying alternating current

Digitized by Google

at 2,000 volts. Besides the requirements of the theatre, this station served about 600 incandescent lamps belonging to private consumers. In 1891 a second generating station was built and supplied with two of the Compagnie Continentale Edison's continuous-current 100-volt dynamos, with an output of 400 kilowatts each. The dynamos were driven by two Weyher and Richemond engines. This station is said to have cost 100,000 roubles, which probably means about £15,000 or £16,000, and for the first two years of working resulted only in a heavy deficit. At the end of 1893 both stations were leased to Mr. Morguliss, an engineer. He paid the town a rental of 25,000 roubles, and received back 20,000 roubles for lighting the theatre, and the town authorities also contracted to take of him current for 1,000 lamps at 35 copecks per kilowatt-hour, or 10 to 12 per cent. reduction on his tariff for private consumers. If the rouble is taken at its nominal value, this price works out at considerably above a shilling a unit. In 1894 there was a further extension involving the installation in the older station of three new Thomson-Houston eight-pole alternators. These were 120-kilowatt machines running at 2,080 volts (alternating) and 115 periods a second. The engines for these came from Tosi's, at Legnano, and the alternators were belt driven. The Ganz machines make only 43 alternations per second, so that there is no question of paralleling. They are, however, still run for the theatre and its neighbourhood, as if the Thomson-Houston machines are used for that purpose the telephones are so much affected as to render speaking impossible. They, however, appear to do most of the other work, which is principally the supply of theatres and public buildings. The distribution is by overhead wires with porcelain insulators. Guard wires are put in where telephone or telegraph lines are met, and the supply wires are crossed to minimise induction. There are about 20 versts (13 miles) of this air line, and a 50 per cent. increase is contemplated during the year, with, of course, further additions at the generating station. The first transformers used were Ganz ones, giving a supply to consumers at 60 volts. Latterly Thomson-Houston transformers have been adopted supplying the current at 104 and also at 52 volts. Most of the installation and wiring work was done by Olschewicz and Kern, the local representatives of a Vienna firm. It may be mentioned that there are a quantity of arc lamps, some at least of which would appear to be alternating-current ones. With such a mixture of machinery from all parts of Europe, it is not surprising that, in spite of a cheap system of distribution, the tariff should be high. Besides the above two stations, there is another one belonging to the Ministry of Commerce for lighting the harbour. It is supplied with Thomson-Houston International Electric Company's plant, and worked by a company for monthly payments from the Government. The South-West Railway have also a continuous-current generating plant for arc lighting and working cranes at the railway station, and another for arc and incandescent lamps at their works.

Commutator Resistance.—In the spring of 1895 Messrs. Cox and Buck, at Columbia College, in the United States, experimented upon the effect of pressure in reducing contact resistance, and determined the friction losses for different brushes; but making the natural but unwarranted assumption that the resistance was the same whether measured by means of one ampere of current or ten amperes, they entirely neglected the effect of varying current density. The matter has since been further investigated by Messrs. H. J. Edsall and M. C. Rorty, and their results, which formed the subject of a thesis at Cornell University, have been published in the New York *Electrical Engineer.* From this it appears that the apparatus employed consisted of a commutator 5⅝in. in diameter, made up of 64 hard copper segments mounted upon a shaft having a pulley at one end to permit its being driven at any desired speed. To secure electrical connection from brush to brush a strip of sheet copper was wound around one end and carefully soldered to each bar. The results for the different pairs of metallic brushes tested were practically the same, and what variations there were in the runs made with carbon brushes may be laid rather to differences in the condition of the commutator surface than to any difference in the behaviour of the brushes themselves. Two typical series of readings were taken for metallic and carbon brushes. These observations were made upon a metallic leaf brush having a contact area of ·4 square inch, and a carbon brush of the Eickemeyer type having an area of ·2 square inch. The first pair had been in use on a 10-kilowatt bipolar Edison machine and the second upon a 20-light Weston arc machine. The resistance curves were both hyperbolas, the one for the metallic brushes being equilateral. The behaviour of the brushes was best shown, however, by the volt-ampere readings. It was found that the fall of potential is independent of current in the case of the metallic brushes and very nearly so for the carbon brushes. In many cases with metallic brushes the fall of potential was actually greater for very small currents than for the heavier ones. One pair gave 1·6 volts drop for four millionths of an ampere, and only ·7 volt drop for 50 amperes. These rather surprising results are explained on the assumption that the coating which forms upon the commutator surface is practically a non-conductor, and that each different current tears it apart to a different degree. The theory is supported by the behaviour of the resistance when sand-paper is applied to the surface of the commutator. Under such circumstances the voltmeter reading falls practically to zero. With metallic brushes oil produces much the same effect by softening the film. Besides testing the effect of current density upon the contact resistance, runs were made to determine the effect of speed and brush pressure. These seemed to show, as theory would indicate, that mere change in the velocity of rubbing had little or no effect, any increase of resistance with speed being due to increased vibration. The curves for resistance as a function of pressure agreed with those obtained by Messrs. Cox and Buck as to form, which was much like that of the curves for resistance as a function of current. In one case, increasing the pressure of a metallic brush from 1lb. to 6lb. per square inch caused a decrease of only 12 per cent. in the resistance. A pair of carbon brushes showed 28 per cent. decrease in resistance for an increase of pressure from ½lb. to 5½lb. per square inch. It thus appears that brush pressure within the usual working limits is not a very important factor in determining the contact resistance. The results of the experimental work may be summarised as follows: (1) Mere change in the velocity of rubbing has no effect upon contact resistance. (2) Within ordinary working limits increase of brush pressure causes only a slight decrease of resistance. (3) Sand-paper used occasionally upon a commutator will greatly reduce the losses through resistance. (4) Oil used with metallic brushes materially reduces the resistance, especially for small currents. The effect is, however, temporary. (5) Both carbon and metallic brushes tend to reach a limiting condition in which the resistance varies inversely as the current. Although there is nothing particularly unexpected in them, Messrs. Edsall and Rorty's results may be worth the attention of central-station engineers.

THE PRINCIPLES OF ALTERNATE-CURRENT WORKING.*

BY ALFRED HAY, B.SC.(EDIN.), A.I.E.E.

(Continued from page 68.)

33. We are now in a position to consider the *growth* of a current in an inductive circuit under a steady impressed E.M.F. At any instant, the impressed E.M.F. may be regarded as made up of two components—viz., the component required to maintain the current through the resistance of the circuit, and the component required to balance the counter E.M.F. due to the inductance of the circuit. The first component is simply the product of the current into the resistance; we shall refer to it as the $r\,i$ component of the E.M.F. The second component is measured by the rate of change of the magnetic flux through the circuit. Let us suppose that the inductance of the circuit is L, and that during t seconds the current has changed from i_1 to i_2; the corresponding change in the magnetic flux is $L\,i_2 - L\,i_1 = L\,(i_2 - i_1)$. The mean *rate of change* of the magnetic flux during the same time is $\frac{L(i_2 - i_1)}{t} = L\frac{i_2 - i_1}{t}$; but $\frac{i_2 - i_1}{t}$ gives us the rate of change of the current. Hence rate of change of magnetic flux $=$ L $\times$ rate of change of current.

It is convenient to use a special symbol to denote the rate of change of the current at any instant, and we shall use i' to denote this rate of change.

If we suppose E to denote the E.M.F. applied to the circuit, we have the relation

$$E = r\,i + L\,i' \quad . \quad . \quad . \quad . \quad . \quad (20)$$

This equation will hold good whether E be constant or not. In the present case we suppose E to be constant, but cases will present themselves later on in which E is variable. The equation expresses the fundamental relation between the instantaneous values of the E.M.F. and current in an inductive circuit, and it is very important that the student should have a perfectly clear conception of the physical meaning of the equation. E, i and i' may all change from instant to instant; but *at any one instant* these three quantities are so related as to satisfy equation (20).

34. From equation (20) we have at once

$$i' = \frac{E - r\,i}{L} \quad . \quad . \quad . \quad . \quad . \quad (21)$$

This equation enables us to calculate i' for any given value of i. The relation between these two quantities may be represented by a straight line, as shown in Fig. 25. The greatest rate of change of the current, O A $\left(= \frac{E}{L}\right)$, occurs just at the commencement, when the value of the current is zero. As the current increases, the *rate* at which it does so diminishes, until finally, when the current has reached its steady value, O B $\left(= \frac{E}{r}\right)$, the rate of change becomes nothing.

The student will readily see that the rapidity with which the current rises to any fraction of its steady value will depend on the inclination of the line B A in Fig. 25 to the vertical. The greater this inclination the more rapidly will the current establish itself in the circuit. For if we suppose that the line B A is displaced into the position B A′ so as to become more inclined to B O, then for any given value of the current, such as O P, its *rate of growth* is *increased* from P Q to P Q′; hence, the current will attain its steady value more rapidly in the second case. *Any change in the circuit, therefore, which causes the point A to travel away from the origin will accelerate the rise of current in the circuit.* Now, for a given value of the steady current, $\frac{E}{r}$, the distance of A from the origin may be increased in two ways: first, by *diminishing* L; secondly, by increasing *both* E and r, so that the ratio $\frac{E}{r}$ remains unaltered. In most cases which present themselves in practice it is not practicable to reduce L, but we may in most cases adopt the second expedient by connecting in series with the inductive resistance a large non-inductive one (which adds practically nothing to L but materially increases r), and using a higher E.M.F.

35. Since the rapidity with which a current establishes itself in a circuit depends on the inclination of the line B A, it is convenient to know what the angle O A B is. This angle is generally assigned in terms of its tangent (Art. 2), and the tangent is termed the *time-constant* of the circuit. Now $\tan \text{O A B} = \frac{\text{O B}}{\text{O A}}$—*i.e.*, since O B $= E/r$, and O A $= E/L$, $\tan \text{O A B} = \frac{L}{r}$, so that we have the following alternative definition:

The time-constant of a circuit is the quotient of its inductance by its resistance.

In a circuit having a large time-constant, the current takes a comparatively long time to rise to its steady value; in a circuit whose time-constant is small, it establishes itself very rapidly.

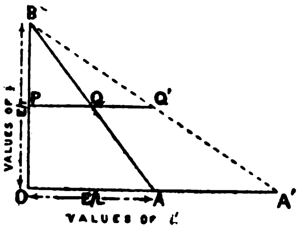

Fig. 25.

The diagram of Fig. 25 may be used for an approximate method of determining the relation between the current and the *time*. The method is based on the assumption that the rate at which the current changes does not vary continuously, but by a series of small steps. The student will best understand the method by studying the following numerical example.

36. Let an E.M.F. of 100 volts be applied to a circuit whose resistance is 10 ohms and inductance ·05 henry. The value of the steady current is $\frac{100}{10} = 10$ amperes. In Fig. 26, let O be taken as origin, and let the vertical axis be the axis of current. We shall suppose that the time is measured along the horizontal axis to the right of the origin. Lay off a length O B $=$ 10 units to represent, on a convenient scale, the 10 amperes. From O lay off O A $= \frac{E}{L} = \frac{100}{\cdot 05} = 2{,}000$, to a convenient scale. The line O A in Fig. 26 corresponds to the line O A in Fig. 25, and it represents the rate at which the current increases just at the commencement. Divide O B into any number of equal parts, say 20; each of these divisions will therefore represent ·5 ampere. The greater we make the number of these divisions the more accurate will be the result. Through the middle point of each division draw a line parallel to O A until it intersects the line A B. The first of these lines determines the mean* rate of variation of the current between the values 0 and ·5 ampere, and we shall suppose that as the current increases from nothing up to ·5 ampere, its rate of change, instead of varying, remains constant and equal to the mean rate of change between those limits. When the current has reached the value ·5, we suppose that its rate of change *suddenly* diminishes, and remains constant while the current increases from ·5 to 1 ampere, and equal to the mean rate of change between those values of the current, and so on. This supposition is equivalent to assuming that the line A B, instead of being a continuous straight line, is a stepped or zig-zag line (shown dotted in Fig. 26).

In order to construct the curve connecting *time* and *current*, we proceed as follows. From the diagram to the left of O B we find that the mean rate of change of the current between 0 and ·5 ampere is 1,950 amperes per second. This means that the current would change by

* Based on a series of evening lectures delivered at the University College, Liverpool.

* Mean, that is to say, with respect to the current, but *not* with respect to the *time*; and that is precisely where the error is introduced in this approximate method.

Digitized by Google

one ampere in $\frac{1}{1950}$th, or ·000513, of a second; hence it would increase by ·5 ampere in ·000256 second. We thus get one point on our curve (*a* in Fig. 26). To obtain the next point, we notice that between ·5 ampere and 1 ampere the mean rate of increase of the current is 1,850 amperes per second. Hence the current would increase from ·5 ampere to 1 ampere—*i.e.*, by half an ampere, in $\frac{1}{1,850 \times 2}$ = ·00027 second. Corresponding, therefore, to one ampere we have the time ·000256 + ·00027 = ·000526 second. This gives us another point, *b*, on our curve. By proceeding in this manner we obtain 20 points. According to the supposition which we have made, the growth of the current would be represented by the open polygon formed by joining the points determined as above by straight lines. But we know that the rate of change of the current varies *continuously*, and not by sudden steps. Hence it will be more correct to draw a continuous curve through the points. This curve is shown in Fig. 26.

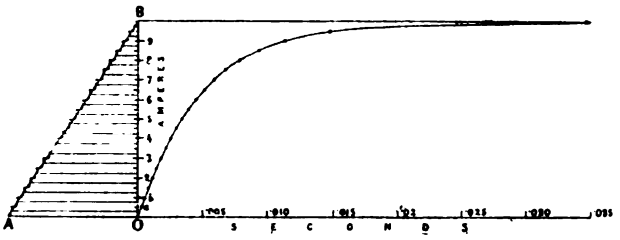

FIG. 26.

The approximate method just explained for drawing the *time-current* curve presents no difficulties, and is capable of furnishing very accurate results. The accuracy may be increased as much as we please by sufficiently increasing the number of points on the curve.

As a matter of fact, the current never reaches the value which we call the "steady value" $\left(\frac{E}{r}\right)$. But after a very short time from the instant of closing the circuit it differs so very little from its steady value, and grows so very slowly, that for all practical purposes it may be regarded as having reached the steady value. Thus, in the example considered, it may be shown that the current falls short of its steady value by only $\frac{1}{100}$th of 1 per cent., ·046 second after closing the circuit.

37. We now pass on to the consideration of an inductive circu t conveying an alternating current which is a simple harmonic function of the time. We shall suppose that the resistance, *r*, and inductance, L, of the circuit are known, and that the maximum value of the current is I. The problem is to find the impressed E.M.F. (Art. 26) in the circuit.

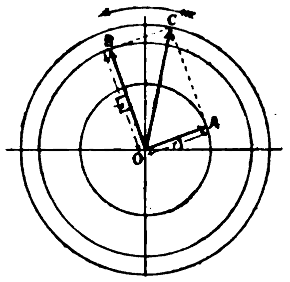

FIG. 27.

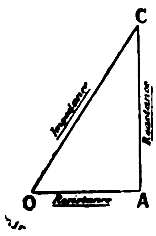

FIG. 28.

At any instant, if *i* denote the current, we have the following relation (Art. 33):

$$\textit{impressed}\ \text{E.M.F.} = r\,i + L\,i',$$

where *i'* stands, as before, for the rate of change of the current at the instant considered. The impressed E.M.F. is thus seen to be made up of two components, the component *r i*, which serves to maintain the current through the *resistance* of the circuit, and the component L *i'*, which balances the E.M.F. called into play by the *inductance* of the circuit. Since we suppose the current to be a simple harmonic function of the time, we may represent its value at any instant (Art. 22) by the projection on the vertical axis of a rotating vector of length I. By taking another rotating vector, O A (Fig. 27), of length *r* I (the vector being in the same phase as that which represents the current) and projecting it on the vertical axis, we obtain an alternating vector whose value at any instant gives us the *r i* component of the impressed E.M.F. Again, since the current is capable of being represented by an alternating vector, its rate of change will be represented by another alternating vector (Art. 22), whose amplitude is *p* I (*p* standing for the angular velocity), and which is $\frac{\pi}{2}$ (or 90deg.) in advance of it as regards phase. The rate of change of the current would therefore be obtained by projecting a rotating vector of length *p* I, and at right angles to O A, on the vertical axis; and the L *i'* component of the E.M.F. (= L × rate of change of current) may be represented by the projection on the vertical axis of a rotating vector O B (Fig. 27) of length L *p* I, which is at right angles to O A. We thus see that the impressed E.M.F. is the sum of two alternating vectors. In order to obtain this sum of the projections of O A and O B, we may first find the resultant O C of the two rotating vectors O A and O B (Art. 18 and Fig. 11). The projection of the rotating vector O C on the vertical axis gives us the instantaneous value of the impressed E.M.F.

38. We have thus shown that if the current in a circuit of constant inductance obeys the simple harmonic law, the impressed E.M.F. is also a simple sine function of the time. In order to find the maximum value O C of this E.M.F., we have merely to notice that since the triangle A O C is right-angled,

$$\begin{aligned} OC &= \sqrt{OA^2 + AC^2}, \\ &= \sqrt{OA^2 + OB^2}, \\ &= \sqrt{r^2 I^2 + L^2 p^2 I^2}, \\ &= I\sqrt{r^2 + L^2 p^2}. \end{aligned}$$

From Fig. 27 we also see that the current is not in phase with the impressed E.M.F., but *lags* behind it by an angle A O C. Now

$$\tan AOC = \frac{AC}{OA} = \frac{LpI}{rI} = \frac{Lp}{r},$$

i.e., the tangent of the angle of lag is equal to the quotient of L*p* by *r*.

If we now suppose that a simple harmonic E.M.F., E sin *pt*, is applied to a circuit of resistance *r*, and inductance L, then it follows from the above that the current is given by

$$i = \frac{E}{\sqrt{r^2 + p^2 L^2}} \cdot \sin(pt - \theta) \quad . \quad . \quad (22)$$

where θ is an angle such that its tangent is equal to $\frac{pL}{r}$.

If we use I to denote the maximum value of the current, then

$$I = \frac{E}{\sqrt{r^2 + p^2 L^2}} \quad . \quad . \quad . \quad . \quad . \quad (23)$$

These equations are of fundamental importance in the theory of alternating currents, and should be committed to memory by the student.

Equation (23) shows that the maximum value of the current is obtained by dividing the maximum value of the E.M.F. by the quantity $\sqrt{r^2 + p^2 L^2}$. This quantity, which is the analogue of resistance in a continuous-current circuit, is termed the *impedance* of the circuit. The quantity *p* L is called the *reactance*. We thus have

$$(\textit{impedance})^2 = (\textit{resistance})^2 + (\textit{reactance})^2;$$

and if θ denote the angle of lag of the current behind the E.M.F., we have

$$\tan\theta = \frac{\textit{reactance}}{\textit{resistance}} \quad . \quad . \quad . \quad . \quad . \quad (24)$$

The diagram (Fig. 28), which a reference to Fig. 27 will at once enable the student to understand, may help to exhibit the important relations between the quantities we have just been considering.

39. The variations of an alternating E.M.F. or current which

Digitized by Google

is a simple sine function of the time (Art. 22) are always capable of being represented by a simple sine curve, such as that which is shown in Fig. 12. The time taken by the E.M.F. or current to run through a complete cycle of values is, as has already been explained (Art. 14), termed a *period.* The number of complete periods in one second is termed the *periodicity*. The symbol ~, introduced by Mr. Mordey, is used to denote the periodicity. Thus 100 ~ per second means "100 complete periods in every second." If the periodicity n is given, then, remembering that $p = 2\pi n$ (Art. 17), we can at once calculate the reactance, and hence also the impedance, for a circuit whose resistance and inductance are known. The periodicities commonly used in this country vary from 40 to 100 ~ per second.

40. We shall now apply the results established above to a numerical example.

Let an alternating simple harmonic E.M.F. whose maximum value is 100 volts be applied to an inductive circuit whose resistance is 18·2 ohms, and inductance ·0796 henry. The periodicity we shall suppose to be 100 ~ per second. In order to find the maximum value of the current we must calculate the impedance Now, $p = 2\pi \times 100 = 628{\cdot}32$, so that

$$\text{reactance} = p\,L = 628{\cdot}32 \times {\cdot}0796 = 50.$$

Hence

$$\text{impedance} = \sqrt{r^2 + p^2 L^2} = \sqrt{18{\cdot}2^2 + 50^2} = 53{\cdot}21.$$

Therefore,

$$\text{maximum value of current} = \frac{\text{maximum value of E.M.F.}}{\text{impedance}} = \frac{100}{53{\cdot}21} = 1{\cdot}88 \text{ amperes.}$$

Next, if θ denote the angle of lag,

$$\tan\theta = \frac{\text{reactance}}{\text{resistance}} = \frac{50}{18{\cdot}2} = 2{\cdot}747.$$

In order to determine θ, we may, as in Fig. 28, construct a right-angled triangle O A C whose sides O A and A C are equal to the resistance and reactance respectively. The angle A O C will then be the angle of lag. By measuring this angle with the protractor the student will find that it is about 70deg.

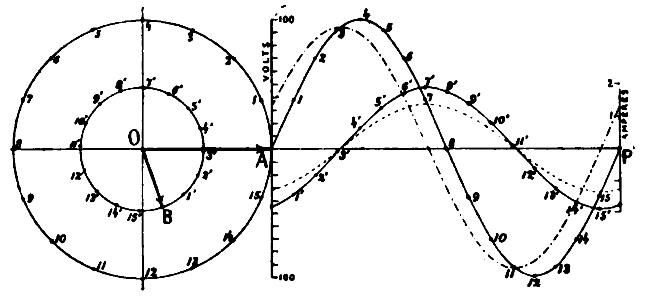

Fig. 29.

To construct the E.M.F. and current curves we may adopt the method explained in Art. 20 and illustrated by Fig. 12. Take one rotating vector, O A (Fig. 29), of length = 100 (to a convenient scale), and another, O B, of length = 1·88, inclined to the first at an angle of 70deg. As the two vectors rotate with the same angular velocity, p (= 628·32 radians per second), round O, the projection of O A on the vertical axis gives the instantaneous value of the E.M.F., while that of O B gives the instantaneous value of the current. By dividing the circumferences of the two circles along which the extremities of the rotating vectors travel into the same number of equal parts, and proceeding as explained in Art. 20, we derive the E.M.F. and current curves shown to the right of Fig. 29. The points of division 1, 2, 3 . . ., and 1′, 2′, 3′ . . ., are so related that they correspond to simultaneous positions of the two vectors. The distance A P corresponds to a period—*i.e.*, to ·01 second.

41. The impressed E.M.F., as we have seen, may be regarded as made up of two components, the one to overcome the resistance of the circuit (the $r\,i$ component), the other to balance the effect due to the induced E.M.F. We can readily analyse the impressed E.M.F. curve shown in Fig. 29 into these two components. By taking a number of points on the current curves, and multiplying the corresponding ordinates by 18·2 (the resistance of the circuit), we obtain the $r\,i$ component of the E.M.F., shown dotted in Fig. 29. By subtracting the ordinates of the curve so obtained from the impressed E.M.F. curve, we obtain another sine curve, which gives us the component required to balance the E.M.F. due to inductance. This is shown chain-dotted in the figure. These curves might also have been obtained directly by projecting two rotating vectors, the one of length r I and in phase with O B, the other of length L p I and at right angles to O B (*c.f.* Fig. 27). The student will notice that the L i' component of the impressed E.M.F. passes through its zero value when the current reaches its maximum value—*i.e.*, becomes stationary for the moment, so that its rate of change is nothing—and *vice versâ.* This will also be at once evident by referring to Fig. 27.

42. The quantity, then, which determines the amplitude of the current—*i.e.*, its maximum value, Art. 14—in an inductive circuit is not merely the *resistance* of the circuit, but its *impedance.* If the periodicity is low then the resistance of the circuit is more important than the reactance, so that for *very slow* alternations of the E.M.F. the current will depend mainly on the *resistance* of the circuit. As the periodicity increases, however, the *reactance* becomes more and more important, and for *extremely rapid* alternations of the E.M.F. the impedance will depend almost entirely on the *reactance*, the resistance becoming practically insignificant.

In order to exhibit this change of impedance with the periodicity the numerical values of the reactance and impedance corresponding to various periodicities for the circuit already considered have been plotted in Fig. 30. The horizontal straight line above the axis of periodicity, and at a distance of 18·2 from it, represents the *resistance* of the circuit, which is assumed to be independent of the periodicity.* The sloping straight line represents the *reactance*, which increases at a constant rate with the periodicity. Finally, the uppermost curved line gives the values of the *impedance*, calculated from the formula $\sqrt{r^2 + p^2 L^2}$. It will be noticed that for *very low* values of the periodicity, the impedance line is almost coincident

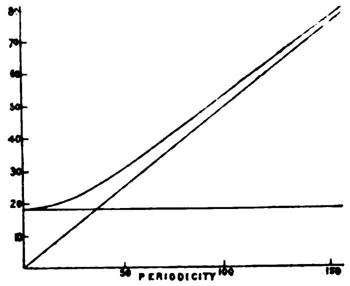

Fig. 30.

with the line of resistance, while for *very high* values it tends more and more towards coincidence with the line of reactance.

We have hitherto supposed that we are dealing with a circuit for which L is a constant. In many important practical cases, L is a variable quantity; this is always the case for any coil containing a core of magnetic material. The simple relations which we have established between the E.M.F. and current will then no longer hold. But the general principles involved will be the same. Thus, the fundamental equation connecting impressed E.M.F. and current will assume the form

impressed E.M.F. = $r\,i$ + *rate of change of magnetic flux,*

instead of the more special and simpler form of Art. 33. The general conclusions regarding the effects of resistance, reactance, and impedance which we have deduced for a circuit of constant permeability will also hold for a circuit containing iron.

(To be continued.)

* As a matter of fact, the resistance is *not* independent of the periodicity, owing to the crowding of the current towards the outer portions of the conductor. This effect will be discussed later.

RAILWAY BLOCK SIGNALLING.

BY J. PIGG.

(Continued from page 69.)

The form of indicator connected in the continuation of the "down" line wire between E and B, at C and D, is shown by Fig. 16. The dials are divided and lettered in the same way as those of the block instruments, but the signalmen at C and D have no control over the indicators.

FIG. 16.—Subsidiary Block Indicator.

They are merely used to indicate the condition of the line between E and B in order that the signalmen at C and D may not undertake any operations involving the fouling of

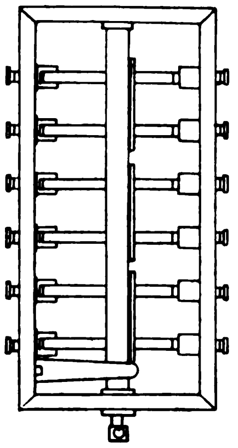

FIG. 17.—Switch (Plan). Instruments in Circuit.

the "down" line under such conditions as, by an error of judgment or failure of apparatus, would lead to an accident.

closing certain cabins at stated periods, and working the traffic between the cabins on each side as a block section. Thus, of three successive cabins, A, B, and C, B may be closed from 10 p.m. to 6 a.m., say, and the section between these times would be from A to C. The alteration in the lengths of the section would be effected by a switch placed in B, which would be turned to the appropriate position

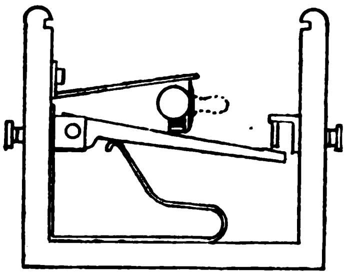

FIG. 18.—Switch (End View). Instruments out of Circuit.

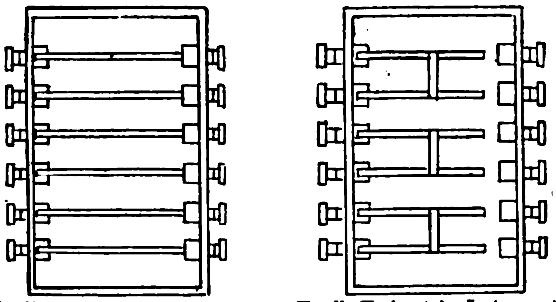
by the signalman before leaving, and after giving notice to A and C by the signals provided in the code for such purpose.

The form of switch generally used for switching three-wire circuits is shown by Figs. 17 and 18, and the diagrams (Figs. 19 and 20) show the connections in the switch for the two positions it can occupy.

FIGS. 19 AND 20.—Three-Wire Block Switch.



Handle Vertical. Instruments in Circuit. Handle Horizontal. Instruments out of Circuit.

The connections for a complete block cabin of the simple character indicated by Fig. 9 are given, diagrammatically,

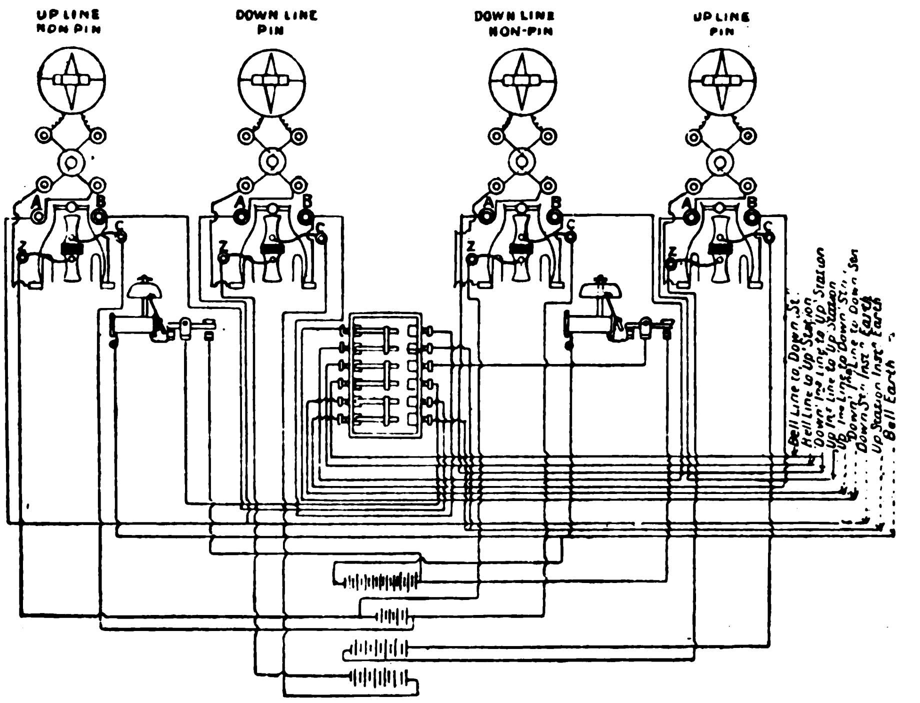


FIG. 21.—Diagram of Connections.

SWITCHING BLOCK APPARATUS.

It frequently happens that a block cabin is not required to be open during the whole 24 hours, owing to the traffic being less than ordinary during part of the time. Advantage is taken of this, wherever possible, to economise labour by

in Fig. 21, in which the switch is shown with the connections arranged as when the cabin is closed. It will be noticed that the two indicating instruments working to the "up" station are in circuit, and will, therefore, reproduce all signals sent from the cabins on either side. The object

Digitized by Google

of this arrangement is to enable the signalman to ascertain, when opening out the cabin for ordinary working, whether any trains are in the section he is about to divide. If the block indicators show that trains are in the section, or that the preliminary signals for trains entering the section have been acknowledged, the signalman at the cabin which is being opened pins the instruments at that place appropriately. If he gets the "Train passing out of section" signal from the advance cabin, he also gives that signal to the cabin in the rear, and afterwards takes all

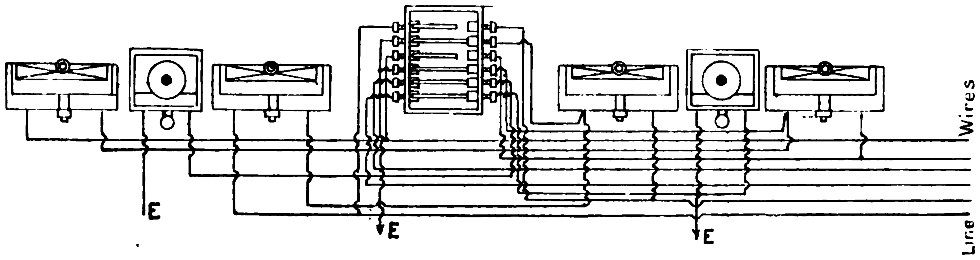

FIG. 22.—Instruments in Circuit—Cabin Open.

succeeding signals himself. The code provides signals which indicate to the cabins on either side when an intermediate cabin is being closed or opened, so that the signalmen at the ends of the long section know when they are working to each other, and when to the intermediate cabin.

Another method of switching instruments in and out of circuit, with a switch of similar construction, is shown in the diagrams Nos. 22, 23, and 24. In Fig. 22 all instruments are earthed at that cabin which is open. In Fig. 24 all instruments are cut out of circuit, and the cabin is closed.

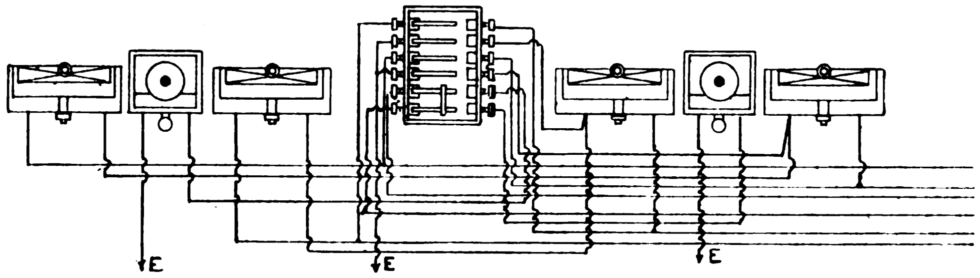

FIG. 23.—Intermediate Position—Cabin about to be Opened.

In Fig. 23 the block indicators are in circuit, but are working through between the cabins on either side. With the switch in the latter position the signalman is able to ascertain whether there are any trains in the section he is about to divide, in order that he may arrange to exhibit the proper indications on the block instruments at the two cabins he will work to.

The essential difference between the two methods of switching is that with the switch shown in Fig. 21, one instrument for each line is constantly in circuit; with the

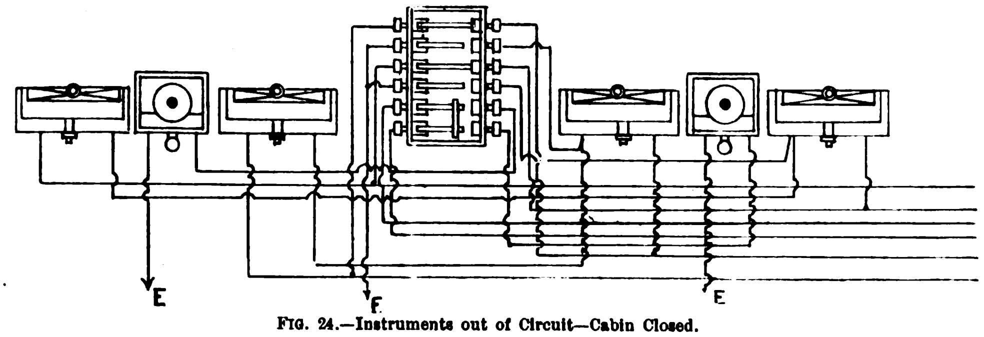

FIG. 24.—Instruments out of Circuit—Cabin Closed.

switch shown by Figs. 22, 23, and 24, all instruments are cut out of circuit until such time as they are required to be brought into operation. It will be noticed that with either form of switch no alteration of battery power is made at the cabins which are working through another which is closed. The batteries are always installed with a margin sufficient for the maximum distance they have to work through.

GATE CROSSINGS.

It frequently happens that a highway crossing is situated between two block cabins. Such crossings are, of course, provided with a gatekeeper, but if the crossing is situated on a sharp curve, or during foggy weather, the gatekeeper has some difficulty in assuring himself that no danger exists in opening the gates for vehicles, foot-passengers, or, worst of all, cattle passing along the road. Matters were improved by providing the gatekeeper with an intermediate bell connected in the block bell circuit, which reproduced all the bell signals exchanged between the cabins on each side of the crossing. This method was imperfect, in that the gatekeeper had to distinguish the different classes of signals from each other, to rely on his memory after the signals had passed, and was unable to distinguish between signals for "up" and "down" trains.

The apparatus now provided is shown by Fig. 25. The small needle indicators are inserted in the "up" and "down" block indicator circuits, and the bell is inserted in the block bell circuit as before. The gatekeeper has no control over the instruments, and is not called upon to do any work in connection with them, but by the aid of the indicators he is able to see at any time whether a train is approaching from either direction, and from the character of the indication, "Train on line" or "Line clear," is able to judge its approximate distance.

SIGNAL REPEATERS.

When signals are not visible from the cabin from which they are worked, some means of indicating the position of the arm becomes necessary. At one time it was customary to fix a small subsidiary signal in a position where the signalman could see it, and arrange it to be worked from the same wire as the signal it was intended to represent. Such mechanical repetition had many defects and was unreliable, and electrical methods of repeating signals were early brought into use.

The forms that signal repeaters have taken at various times and in various hands have been numerous. Some have been miniatures of the signal and arm, others have the indications lettered on dials, and the position of the arm is shown by relative positions of the pointer, or the indications exhibited. Some repeaters show "off" and

Digitized by Google

"on" only. Others have been made to show "on," "caution," and "off," whilst still others show "on," "out of order," and "off." Some forms of repeaters require two wires, but the majority only require one; some forms require continuous currents to maintain the "on" positions, others to maintain the "off" position, whilst still others require continuous currents for both "on" and "off." The disc indicator, shown in Fig. 26, requires continuous currents for both "on" and "off"; the semaphore form shown in the same figure requires a continuous current to maintain the "on" position, whilst the needle form of indicator shown by Fig. 28 requires continuous currents for the "off" and "out of order" positions.

The construction of the contact-boxes at the signal for providing the necessary indications is naturally governed by the character of the indications decided upon as desirable. An earlier form of contact-box and the method of fixing is shown in Fig. 27, where the movement is obtained from the rod at a point between the counterweight and the arm. In

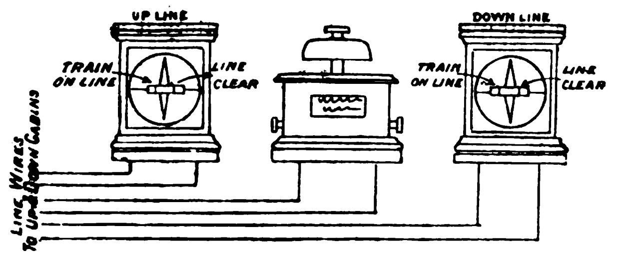

FIG. 25.—Gate Crossing Equipment.

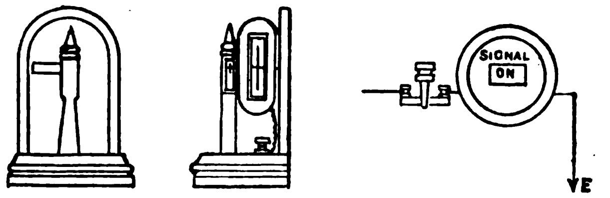
this method the indicator shows two positions only—"on" and "off," the "on" position being the normal indication when no current was passing, and the "off" being maintained by a continuous current.

Consideration of the conditions of working shows that such an arrangement lacks the reliability so important a piece of apparatus should have. In the first place, the point indicated is not that of the arm itself; in the second place, the apparatus is self-testing in one position only. If the rod working the signal arm broke between the contact-box and the arm, or if the key fixing the arm to the spindle slipped out, the arm would indicate "off" whilst the electrical repeater would be showing "on."

Further consideration shows that the relative positions of the signal lever, signal arm, and electrical repeater are of great importance, and that there exists a great necessity for the repeating apparatus being self-testing in the "on" position. If the signal arm is "on" when the signalman expects it is "off" no accident is likely to occur, and slight delay to traffic is the only probable consequence. If, however, the signal is "off" when the signalman expects that it is "on" the consequences may be very different, since it

FIG. 26.



Semaphore Distant Indicator. Disc Indicator with Plug Switch

is the signal arm which ultimately controls the passage of traffic, and all other apparatus, mechanical or electrical, are merely accessories used to ensure the exhibition of the proper outside signals for the time being.

The forms of contact-box shown by Figs. 28 and 29 are fixed concentrically with the spindle of the signal arm, and obtain the motion from the movement of the spindle. They are used in connection with the needle form of repeater shown in Fig. 29. With this form of repeater three positions are shown—"on," "out of order," and "off"; and Fig. 29 is drawn to show the "out of order" position. This indication, as will be seen, is an intermediate one between the "on" and "off" positions of the arm, and must be passed over each time the arm passes from "on" to "off," and *vice versâ*. The chief use of this indication is to show that the signal arm is *fully* "on" or "off." An "out of order" signal would be shown on the electrical repeater instead of an "off" signal in one case, or an "on" signal in another case, if the wire working the signal has become slack or tight from expansion or contraction respectively, and such an indication would be interpreted by the signalman as indicative of the necessity for regulating the wire working the mechanical signal.

It will be noticed that the movement indicated is not that of the arm but that of the spindle; and that the

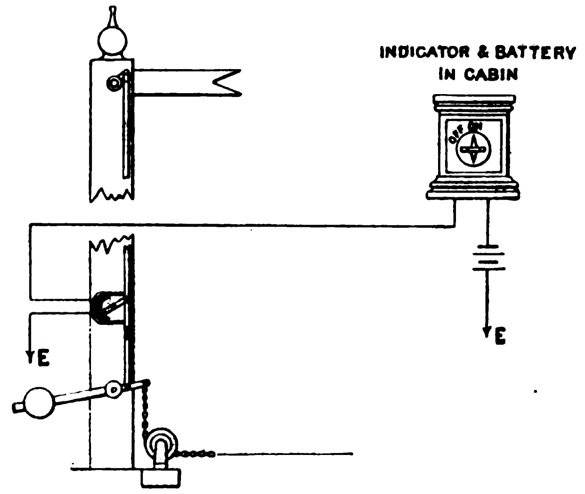


FIG. 27.

removal of the key fastening the arm to the spindle would allow the signal arm to fall, without effecting a corresponding change of position of the electrical repeater. It is true that the position the arm would take up under these circumstances would, if noticed by a driver, be regarded with suspicion, but it should not be forgotten that it is the signalman for whom the repeater is provided, and he would have no notification of the position of the arm being other than that corresponding to the position of the lever working it.

The "out of order" indication of the form of electrical repeater shown in Fig. 29 is of some interest when its

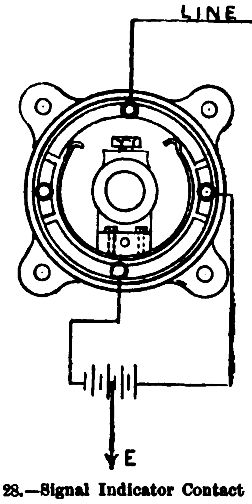

FIG. 28.—Signal Indicator Contact Maker.

significance is understood, and the limitations imposed by the form of instrument and the method of using are considered. As has been stated, the "out of order" indicates a discrepancy between the relative positions of the signal arm and the lever, and so far it is a true "out of order" indication. Whilst this is so, it will be observed that owing to the repeating apparatus not being self-testing in the "on" position, conditions may easily arise where the indication of the electrical repeater may differ from the actual position of the arm, and the latter differ from the position of the lever. Further, a defect in the repeating apparatus, if it occurs when the signal is "on," affords no indication of its existence to the signalman.

To the writer it seems unsound to treat the signal and the repeating apparatus as different pieces of apparatus. Rather, it seems, that they should be considered as one,

Digitized by Google

and the "out of order" signal should be such as not only indicates a discrepancy between the positions of the arm and lever, but also a defect in the repeating apparatus. In short, an efficient repeating apparatus should do, for a signal which is out of sight, all that a signalman can do for himself in connection with a signal within sight.

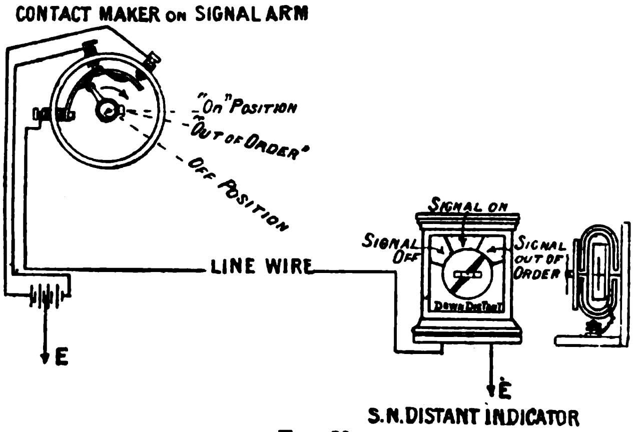

Fig. 29.

Another form of contact-maker, and the method of attaching to the signal, is shown by Fig. 30. It is used in conjunction with the disc indicator shown in Fig. 26. The "on" and "off" positions are both maintained by continuous currents: if from any cause the circuits are broken, the indicator takes up an intermediate position as shown in Fig. 30. This form would appear to possess considerable advantages over the forms shown by Figs. 27, 28, and 29 in that the movement indicated is that of the arm itself, and the apparatus is self-testing in any position. The intermediate position shown by Fig. 30 is a true "out of order" signal and is shown not only when the arm occupies a different position to that of the lever, but also when a defect occurs in the electrical repeating apparatus. A

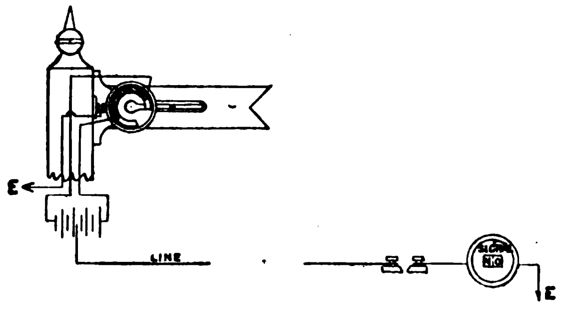

Fig. 30.

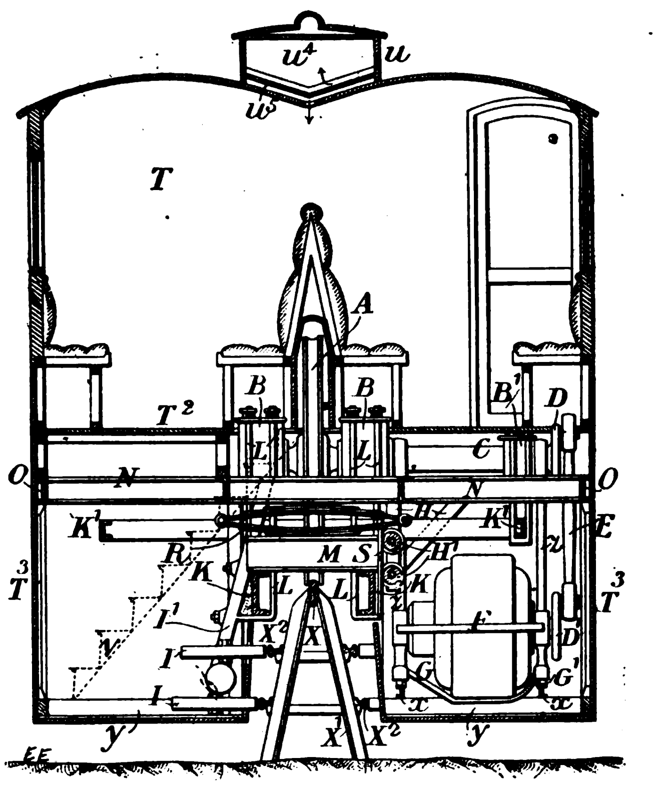
small peg switch is provided by which the circuit may be disconnected during such times as the signal is not being used, in order to prevent the batteries being run down unnecessarily. As the Board of Trade inspectors require signal indicators to be fixed in plain sight and immediately opposite the lever working the signal, there is not much danger of the absence of the peg being unnoticed when the apparatus is being brought into use. At the same time, combinations of circumstances may arise in which the absence of the usual indication would be undesirable.

(*To be continued.*)

LIGHTNING EXPRESS RAILWAY TRAINS.

On Monday last we inspected a model of Mr. F. B. Behr's lightning express trains by invitation. The method devised by the inventor for the attainment of average speeds of from 100 to 150 miles per hour has been before the public for some years. The feature of the departure from existing practice is that of supporting the weight of the train on one rail only. The simplicity of the track is not in any way increased by the reduction of the number of rails from two to one. It appears from our talk with Mr. Behr that four guide rails become necessary, and that the central weight-bearing rail has to be supported at from 39in. to 60in. above the surface of the ground. The general arrangement of the track is seen in the illustration, which also shows an end section of the car. Each carriage will have its own driving power, so that there will be little stress in the couplings. We had a long and most interesting conversation with Mr. Behr on his details of design, and were pleased to hear that he is constructing a trial track at Brussels. It will form one of the attractions of the 1897 exhibition to be held at that city. The line at Brussels will be about 3½ miles long, and will be practically oval in form. The end curves are, however, arcs of circles. We understand that a speed of 95 miles per hour has been guaranteed on these curves, which have a radius of only some 550 yards. From a pamphlet given us, dated 1893, we find the mechanical stress has been well considered, but we fail at present to see that the scheme has exceptional advantages over the ordinary railway. The Brussels line will, however, give a good trial to the proposed arrangement, and if the speed guaranteed can be maintained with safety it must be quite



Section of Carriage and Track of High-Speed Train.

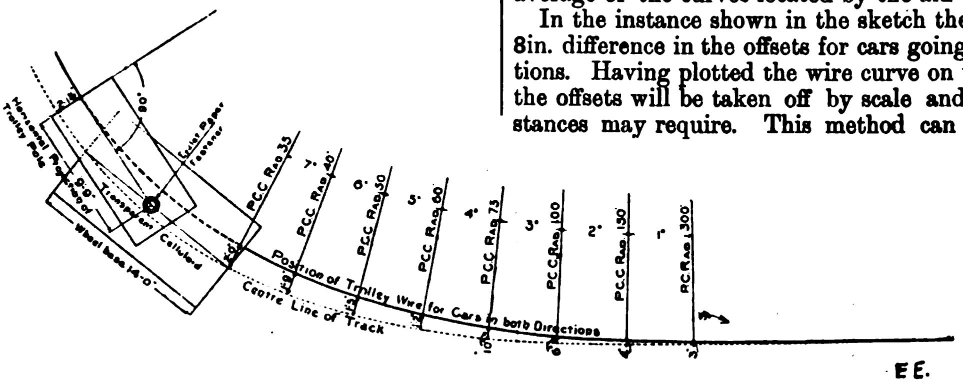
safe on a straight track. The electrical details of this trial line have been placed in the able hands of T. Parker, Esq., of Wolverhampton, so that nothing in that section of the problem will suffer from want of experience. The mechanical stress when running at 95 miles per hour on the above-mentioned curves reaches an alarming amount. Thus, the centrifugal force tending to throw the cars outwards reaches the respectable figure of 20 tons. This stress is to be taken by the guide wheels on the inside. Then we are assured that the guide wheels on each side of the car are so linked together that the pressure on both sides is bound to be equal. If this should really be so, we wonder what driving power will be required on the curve, as it would appear from the above that the guide wheels will seize the rails.

The following are the improvements claimed by Mr. Behr, the mention of which may be of interest to those of our readers not already acquainted with this invention.

Firstly, the carriages have a considerable total length to enable them to pass readily round sharp curves. This is effected by constructing the carriage in two or more separate parts, joined together by a pivot or universal joint. A flexible enclosure covers a platform between the two adjoining parts, from which access is gained to each part. Each half is supported on the rail by two driving wheels, placed as close as practicable together so as to obtain a comparatively small fixed wheel base.

Digitized by Google

Secondly, the centre of gravity of the carriage is kept below the level of the line of rail, even when the entire floor for the passengers is raised above the line of rail. This is effected by placing the motors that propel the carriage at the bottoms of the two lower parts of the vehicle, and so arranging them that although they partake of the vertical motion of the carriage body upon its springs, the distance between their driving shafts and the driving wheel axles, by which they are connected by driving gear, shall always remain constant.



Method of Locating Trolley Wire on Spiral Curves.

Thirdly, the carriage body, though having a vertical motion on springs, is so guided that it cannot move laterally; this is effected by constructing the framing carrying the driving wheels and bogie entirely separate from the framing of the carriage body and guiding the former in a vertical position by means of guide wheels running on lateral guide rails on the line rail supports. The framing of the carriage body, which rests upon the wheel framing with springs, is prevented from lateral motion by providing the wheel frame with vertical rails, against which bear rollers attached to the carriage body.

Fourthly, two guide rails are provided, situated one above the other, against which bear two corresponding guide wheels on each side of the wheel frame of the carriage. In order to ensure that both wheels shall always be kept automatically in contact with both the guide rails so as to distribute the lateral strains on the carriage uniformly over both, the guide wheels are mounted upon vertical arms projecting upward and downward from a horizontal axis that can turn in bearing in brackets on the wheel frame.

Whatever be the result of the Brussels trial line, we consider that Mr. Behr deserves credit for the energy he has thrown into the subject, and for the fact that the money to equip this line is provided privately by himself and a few friends.

THE CORRECT POSITION OF A TROLLEY WIRE OVER CURVES.

Mr. C. A. Alden, writing to the *Street Railway Journal*, describes the following method of graphically ascertaining the correct position a trolley wire should take over a curve on an electric railway. Mr. Alden says that the proper location can be easily found by the use of a template of the essential elements of the problem—*i.e.*, the wheel base and the horizontal projection of the trolley pole.

Having a plan of the curve for which the location of trolley wire is desired to a scale of 5ft. to the inch, or larger, take a piece of thin transparent celluloid and cut it to the length of the wheel base (on the same scale as the plan) and mark with a sharp point a line for the centre line of the car and mark the centre of the wheel base. Then cut another piece a little longer than the horizontal projection of the trolley pole. Mark a line on this at right angles to one end and mark the length of the horizontal projection of the trolley pole from this end. Then join the two pieces at the centre of the wheel base and centre of the trolley base by an eyelet paper-binder, loosely enough so that they may turn with some little friction.

Then, placing the template upon the plan of the curve so that the wheel base coincides with the centre line of the curve, and swinging the "trolley pole" until the square end is radial to the track curve, we can mark a point which will be approximately on the wire curve. Carrying this process through the spiral to the point where the offset becomes constant, we next sketch in the approximate location through the points just found. Going over this again, and making the "trolley pole" square with radial lines from this approximate location instead of those of the track curve, we can lay down the final location of the wire for cars to run in one direction. If cars are to run in both directions the location should be found by taking an average of the curves located by the aid of the template.

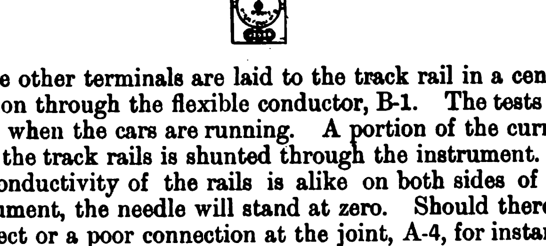
In the instance shown in the sketch there is from 6in. to 8in. difference in the offsets for cars going in opposite directions. Having plotted the wire curve on the plan, of course the offsets will be taken off by scale and used as circumstances may require. This method can also be used for locating frogs over complicated switchwork when the curves are compounded, in finding the proper position for the trolley wire in a carhouse door, and in other ways which will suggest themselves to the constructing engineer. The time taken for the operation, having the plan and template in hand, should be trivial. If the outer rail of the curve is elevated the trolley wire should be set in towards the centre of the curve an additional amount equal to

$$\frac{\text{Elevation} \times \text{height of trolley wire above rail}}{\text{gauge}}.$$

HENRY'S RESISTANCE DETECTOR FOR RAIL JOINTS.*

The object of this instrument, invented by Mr. John C. Henry, of Denver, Col., is to make an examination as to the conductivity of the joints connecting the track rails. Heretofore the only method of testing the bonds when any trouble occurred was to open the pavement and replace all the bonds, both good and bad.

By the Henry method an electrician, with the assistance of a couple of boys, is enabled to examine the condition of the joints on several miles of road in a day, and can mark the defective ones for repairs. The theory on which the method works is as follows: The instrument, which is called a "resistance detector," is a specially designed differential ammeter, which is so arranged that opposing magnet coils influence the needle. Those coils are connected to the portable flexible conductors, B and B-2.



The other terminals are laid to the track rail in a central position through the flexible conductor, B-1. The tests are made when the cars are running. A portion of the current from the track rails is shunted through the instrument. If the conductivity of the rails is alike on both sides of the instrument, the needle will stand at zero. Should there be a defect or a poor connection at the joint, A-4, for instance, more current will flow around that joint through the right-hand coil of the instrument and the lead, B-2. In consequence, the instrument becomes unbalanced, and the pointer shows the direction of the cause. By closing in with the conductors, B and B-1, the bad joint can be located and marked for repairs.

BOUND VOLUMES.

Vol. XVI. of new series of "The Electrical Engineer" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

CABLES.

Many years ago an educational reformer remarked that reforms were obtained, not by once showing existing methods of procedure wrong, but by continuously, and over a considerable period of time, pointing out their defects. It is the constant dropping of water that wears away the stone; hence with such views and axioms before us we have no hesitation in again and again calling attention to points which, under certain circumstances, are apt to be overlooked. Initial expense *v.* maintenance might well be a text fixed above the entrance doors of all central stations. From all sides we are constantly hearing strong criticisms about stations designed evidently without due consideration of ultimate requirements. At various times specific points have been discussed in these columns, but there is one which has not had its due share of discussion. We refer to cables. In many instances the cables originally laid have had to be replaced, in some cases more than once. It would be an interesting paper that dealt completely with this subject, giving the exact history of half a dozen well-known undertakings. The explanations added to estimated costs and balance-sheets frequently contain paragraphs pointing out that a large initial expenditure has been incurred in laying mains which in the early days of the undertaking will not be fully utilised, but with increased demand for current will be brought into full operation. That is all very well, and no engineer objects to looking ahead in that manner; but objection is taken to the false economy of putting down mains that will be utilised to their total capacity almost before the end of the first year's working of the station. Here, again, however, we may admit that in many instances the load does increase far more rapidly than could well be anticipated, and the engineer may, under these circumstances, be acquitted from blame. The worst case of all is to be found in the fact that "faulty" cables are far too frequently found in central-station work. Now, the engineer's duty, if he considers the maintenance cost, is to be on the safe side with his mains. There ought not to be a quarter of the faults that are daily found. Each fault is a source of various troubles, all more or less costly, the least of which is perhaps its repair. These things are all well known, and need only to be stated to be accepted as correct. The moral, however, is more to our purpose. The cost of renewals is usually added to capital account; the cost of repairs, the cost of leakage, and other evils, appear among current expenses. A large part, if not the whole, of these costs might be avoided by proper mains in the first instance. Cheap and nasty is as appropriate to mains as to any other article of commerce. We will not go so far as to say that faults can always be avoided; they cannot, but a large percentage of the usual faults as now found in mains can be avoided. The additional initial cost would be a small addition to capital account compared with the cost of renewals, and when within the short period of three or four years renewals have to be made two or three times, the capital

Digitized by Google

account ultimately stands at a much higher amount than it ought to do. To earn dividends upon too great capital means increasing disproportionately the responsibilities of the station officials, dividends are decreased, and price per unit to customers increased, thus doing damage all round. It has not been a general maxim among all manufacturers of mains that insulation for electric light and power purposes is as important a factor in good work as is insulation for submarine cable work. Firms of repute, however, have from the very first understood the importance of the subject; but, as an engineer said the other day, the danger is from mains and wires made by nobody—that is, are not sold as manufactured by a firm of repute. It is not often that mains by unknown makers are used in central-station work, but they have been largely used in private work; hence the necessity of calling attention to the danger of using them. Mr. Nobody, in the case of fault, is the responsible party, and as he cannot easily be found the course usually taken is to replace the main and make as little fuss over the matter as possible.

Another question which will have to be considered is the deterioration of mains. They are not going to last for ever, but as yet we have absolutely no exact knowledge as to the life of a properly constructed, insulated, and laid main. As usual, we shall no doubt be twitted about writing generalities rather than criticising specific instances, but we can assure our readers that under existing legal disabilities specialisation in these matters is impossible. Indeed our purpose will be served if the younger generation of engineers are rendered a little more cautious in writing their specifications, and prefer the safe rather than the cheap, and think more of the future than the present.

CHOKING COILS AND ARC LAMPS.

Our special correspondent's letter in our last issue has had most beneficial results. The editor of our contemporary, after carefully looking up the theory of the matter, now assures his readers that the usual method of obtaining constant current is to vary the voltage of the circuit according to the number of lamps. Mr. Feldmann has, however, the same editor's kind permission to say that the system with choking coils in parallel with arc lamps keeps the voltage constant within limits. The editor admits that this is quite possible, but to support the last part of the letter in question he states that he previously had doubted the veracity of our special correspondent. The interview in question has thus evidently repaid him for reading it a second time.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ELECTRICAL SANITATION.

SIR,—It having come to our knowledge that certain works have been established, advertisements published, and circulars issued by certain persons calling themselves the British Electrozone Corporation, Limited, with reference to the manufacture and sale by them of a disinfectant called "Electrozone" and "Meditrina," and also with reference to a process which they claim for treating sewage by means of electrolysis, we take this early opportunity of informing you that we have commenced proceedings against the British Electrozone Corporation, Limited, for an injunction to restrain them from infringing our letters patent Nos. 5,393 of 1887 and 15,384 of 1887, and for damages, it being alleged by us that the process adopted by the defendants is an infringement of the process protected by our patents.

We may say that our process has been for some time past successfully adopted by the War Office at Netley Hospital, by the Corporation of Ipswich, the marine hospital at Rio de Janeiro, Brazil, by a French steamship company on one of their American line of steamers (the ss. "Paraquay"), and is under consideration by numerous other public bodies both in this country and abroad.

Our process is economical, effective, and continuous, and can be used either in the place of or in conjunction with existing systems of drainage, whether in towns, public or private buildings, ships, or any place where sewage or sewage effluent is required to be treated without interference with existing drains or pipes or cisterns, and it not only removes all noxious smell, but is a complete germicide.

We are also manufacturing the solution in portable form, and shall be pleased to forward samples, with any further particulars or information, on application.—Yours, etc.,

E. HERMITE.
E. J. PATERSON.

AN INTERNATIONAL (?) CONGRESS.

SIR,—Noticing some paragraphs in the technical Press announcing how certain American electricians of high standing were coming over as delegates to an international electrical congress to be held at Geneva in August next, it occurred to me to enquire what questions were to be discussed at this congress, and who were the British delegates. As a member of the Electrical Standards' Committee of the British Association, I had heard nothing of any proposals, nor had I any recollection of any delegates being sent by the Institution of Electrical Engineers.

The replies to my queries only add to my bewilderment. Nothing has been heard of the proposed international congress at the Foreign Office, at the Board of Trade, or at the General Post Office. Mr. Preece, who has attended every electrical congress hitherto, has heard nothing of this affair at Geneva, except what he has gathered from the recent Press paragraphs, has had no invitation to attend, and is not going. No invitations to send delegates have been received by the Royal Society, by the British Association, by the Physical Society, or by the Institution of Electrical Engineers. Nothing is known of the proposal by any of these bodies, except the Institution of Electrical Engineers, the president of which in February last received from Messrs. Palaz and Cuénod, of Geneva, a circular announcing that an electrical exhibition would be held in that city, and asking the "patronage" of the Institution for a congress of electricians to be held in August. The Council of the Institution on March 26 instructed the secretary to reply that they had pleasure in granting this request to enrol the Institution as a patron. At the same time, a corrected list of members of the Institution was forwarded to Geneva. Nothing more was heard until June 19, when a circular, also signed by Messrs. Palaz and Cuénod, dated June 17, and addressed to the *Journal* of the Institution of Electrical Engineers, London, was received by Messrs. E. and F. N. Spon. In that circular the following paragraph occurs: "Invitations to take part in the forthcoming congress [on August 4] are now being sent out, and with the object of making it more generally known we take the liberty of asking you to be kind enough to make this known in your next issue." But the invitations appear never to have been sent! So far as I am able to ascertain, not one single English electrician has yet been invited to attend, nor have any of the scientific societies received any subsequent communication.

It is now July 24; the "International Congress" is to meet on August 4. Even if in the interim invitations

Digitized by Google

should be received, it will be impossible for the societies to appoint delegates.

Any decisions of a congress so composed can carry little weight internationally. Assuredly England is justified in disclaiming beforehand all responsibility for the acts of a congress gathered together in so informal a fashion.—Yours, etc., SILVANUS P. THOMPSON.

July 22, 1896.

[The invitation referred to in the above letter reached us about four weeks ago, and was mentioned in our issue of June 26.—*E E.*]

A STUDY OF A THREE-PHASE MOTOR.*

BY C. W. VAN LAW AND H. S. SIMPSON.

The methods of testing, power measurement, etc., here described are applicable to machines of any size and power, and although the motor tested was a small one the results are typical of motors of this class.

The machine tested was a 3-h.p. Siemens and Halske motor, designed for three-phase currents at low periodicity and at a pressure of 115 volts. It was at first attempted to obtain the power required from two direct-current generators which had been fitted with collector rings for three-phase working, but it was found that these generators would not answer the purpose at all.

After some delay another direct-current generator was tried as an alternator, and found to give very fair results. The armature was of the Gramme type, wound with large wire and few turns per coil, giving a comparatively small self-induction. To convert this machine into a three-phase alternator the commutator was covered by an insulating sleeve of fibre, upon which were mounted three brass collector rings. These were separated by fibre rings, and were connected to three commutator segments 120deg. apart by set screws tapped through the fibre sleeve and into the segments. Thus between any two rings was embraced one-third the armature coils, and three-phase current could be led off from brushes resting on the rings.

The generator was driven from a De Laval steam-turbine which made 24,000 revolutions per minute. This, with 10 to 1 reduction gearing, and a bipolar field, gave a periodicity of 40. Ordinary excitation failed entirely. On open circuit, exciting from an Edison machine, 65 volts could be obtained, but this dropped to 35 on full load. Fluctuations in the Edison voltage also caused great trouble. To avoid these difficulties the following scheme was tried: only a part of the commutator was covered by the collecting rings, and it was determined to take direct current from the bare portion for the fields while taking three-phase current from the rings, thus making the machine self-exciting. This was tried, but variations in the load on the three-phase circuits so changed the "direct" voltage as to make this means unsuitable. We could get 100 volts or so for excitation when the motor was not connected, but this dropped to about 70 when load was thrown on.

This means also failing, the following was finally adopted, very satisfactory results being secured: the Edison generator was placed in series with the direct-current brushes on the generator in question This summation of potential gave 170 volts available for exciting purposes, which could be cut down to the desired amount by a rheostat and bank of lamps.

The fields were now saturated, so that fluctuations in the Edison voltage were hardly noticed. Still, the potential was much lower than was needed for the motor tests, and step-up transformers were resorted to. Only two of these could then be obtained, to transform up all three circuits. This was, nevertheless, accomplished by the following arrangement.

The two primary coils were connected in series, as were also the two secondaries. One brush of the dynamo was connected to the primary junction, and the other to the free ends. If the secondary ends be used as the three terminals of the system, three-phase current may be taken off just as from the machine, but raised in potential by the ratio of the transformer employed. Conard and Ehret transformers were used, and it was found possible, owing to their excellent regulation, to hold the motor's voltage at any point desired by slight variation in the exciting current.

The efficiency runs were first undertaken, the motor being tested at various loads up to 50 per cent. above its rated power, and at voltages from half its normal potential to somewhat above the figure for which it was designed. For these runs the following scheme of connections and arrangement of apparatus was adopted.

Three wires led from dynamo to motor, the two outside wires running to the instrument table and then back, while the third ran direct from one machine to the other, a light potential wire only being carried to the instrument table.

Wires 1 and 3 (Fig. 1) led through two ammeters, A A, of the Westinghouse "Station" type, and thence through the current coils of two Thomson recording wattmeters to the motor. The potential coils for these meters were connected between potential wire 2 and wires 1 and 3, as shown. Both meters were designated for 50 volts only, and to protect their potential coils at the higher voltages used, strings of lamps were connected in these two circuits as indicated in the diagram. Potential wire 2 could not then be connected at such a point as to give about 50 volts across the coils of the instruments. A small switchboard was so arranged that by placing voltmeter terminals in the appropriate clips, voltages could be read across any leg of the circuit (1-2, 1-3, and 2-3) or across the potential coils (1-1′ and 3-3′) very quickly and easily. The switchboard is shown in points 1′-1-2-3-3′ on the diagram.

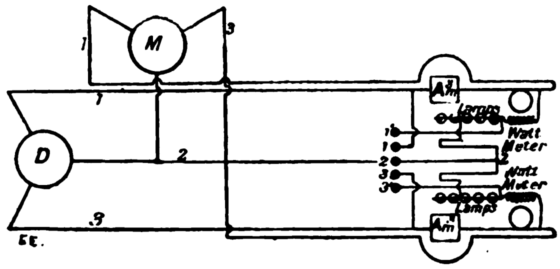

FIG. 1.

Load was applied to the motor by means of a special Prony brake, having water circulation to keep it cool. The load was increased by approximately equal increments from zero to a point where the safe current capacity of the machine was reached. At each load were taken the voltmeter readings referred to above, the wattmeter speeds—time in seconds of a given number of revolutions—ammeter readings in branches 1 and 3, brake load, and simultaneous speeds of dynamo and motor. From these data, and the instrument calibrations, the efficiency, etc., at the various points could easily be obtained.

During these runs one interesting fact was noticed. It may be proven that when the angle of lag in the individual circuits is greater than 60deg. one meter will run backward, and its readings must be subtracted from those of the other wattmeter. At 60deg. this meter stops entirely, while as the angle becomes less than 60deg. it starts again in a positive direction, running faster and faster as its load is increased This was observed during the tests—one meter at light loads running backward quite rapidly. As the load was increased it slowed up, stopped and started in a positive direction; its speed now increased with the load as the other meter had done all along.

At each of the voltages at which efficiency runs were made (65, 80, 95, 110, 115, and 120), a set of torque data was also obtained. Non-inductive resistance was introduced into each of the armature circuits, and the brake load increased as before up to the machine's capacity. At each brake load simultaneous speeds of dynamo and motor were taken, and the results were expressed in speeds in per cent. of synchronism and torque at 1ft. radius. Three different resistances were used at each voltage of approximately 10, 5, and 2½ ohms in each circuit, and these, with the data from the efficiency runs when the armature was short-circuited, gave four curves for each voltage.

In Fig. 2 is shown the efficiency curve taken at 115 volts, and typical for all the higher voltages. The showing

* From the *Electrical Engineer* (New York).

Digitized by Google

made by the motor is remarkably good in many respects. In the case of most small motors the efficiency at anything but full load is very low; and the efficiency rising at once to a fairly high value, a maximum well within the capacity of the motor and a curve nearly flat through a wide range of load about its rated horse-power. Further, as seen from curve D of the torque curves taken at this same voltage (Fig. 3), the slip increases, but slightly from zero to full load, being only 10 per cent. at 50 per cent. overload. The machine can be run at much above its rated capacity, right along, without danger, and is most satisfactory in every way. The efficiency curves taken at other voltages possess much the same characteristics, that at 110 being the

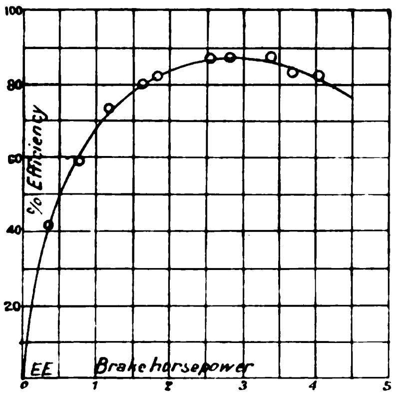

Fig. 2.

highest, reaching a maximum at 88 per cent., and being above 85 per cent. for quite a range of load. The efficiency at 65 volts—half the normal voltage—is still fairly high, reaching a maximum of 76 per cent., and being above 70 per cent. from less than ½ h.p. up. The power, however, is much less at these lower voltages, reaching a maximum of only about 1·3 h.p. for 65 volts.

The torque curves for 115 volts in Fig. 3 are of considerable interest as well. Curves A, B, C, and D are taken with 10, 5, 2½, and 0 ohms respectively, external resistance, approximately, in each armature circuit, for all runs. Curves "D" show only a slight slip from zero to full load for the higher voltages, but this rapidly increases as the lower voltages are used, and at 65 volts "D" drops 10 per cent. at less than half-load. The other curves are chiefly interesting as showing what starting torque might be expected with the various

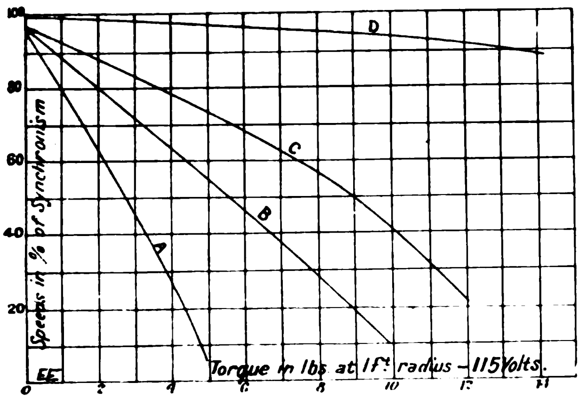

Fig. 3.

resistances used. By producing the curves to intersect the 0 speed line, the starting torque is evidently obtained, and is for the higher voltages amply high for the motor to start under full load, with 2½ ohms in each circuit. A certain resistance may be found for each voltage which will give maximum starting torque; if the resistance be either increased or diminished from this value the torque will fall off rapidly. If the armature be short-circuited, as it is when running at speed, the starting torque produced is very slight; and the machine will burn up before it can be got to start under load. Resistance must first be cut into the armature circuits till the machine starts, and then gradually cut out as the motor speeds up, the armature being fully short-circuited.

ALTERNATE-CURRENT TRANSFORMERS *

BY DR. J. A. FLEMING, F.R.S.

LECTURE I.

(*Continued from page 76.*)

Having thus seen the manner in which we can experimentally determine the form of an E.M.F. or current curve, which represents the different instantaneous values of a

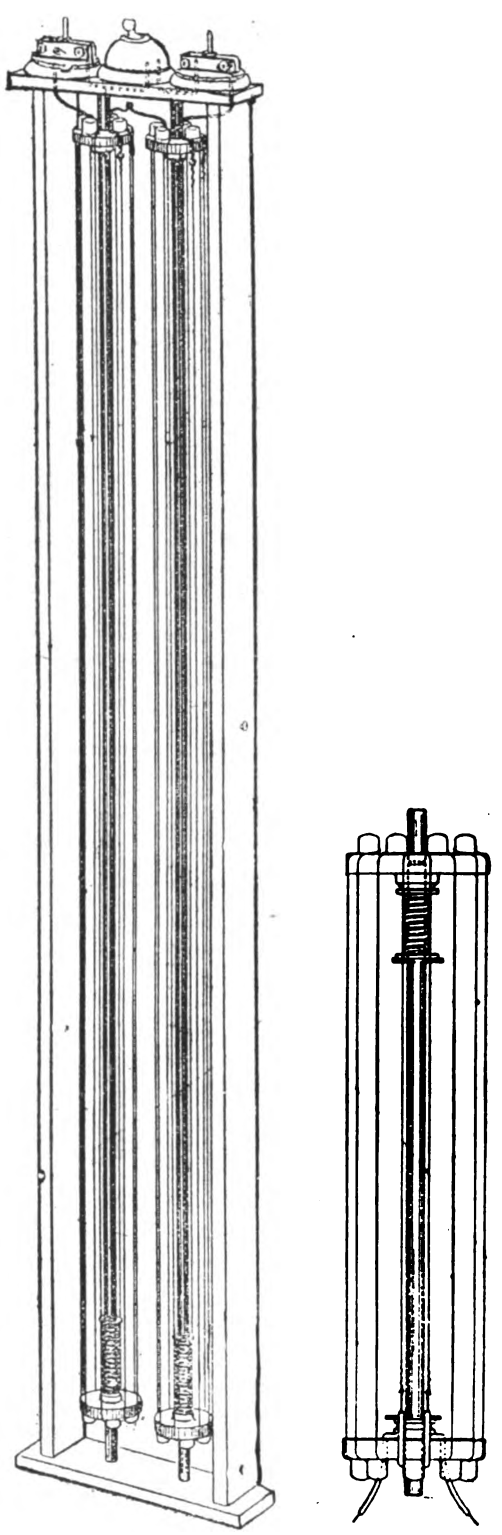

Fig 18

periodic E.M.F. or current, we can now proceed to discuss the manner in which these methods have been applied in the study of the alternate-current transformer. Let us first suppose that the transformer to be studied is a constant-potential transformer, having two windings, a primary and a secondary coil, both wound round an iron core forming a completely closed iron magnetic circuit. Let the primary coil be joined up through a non-inductive resistance, R^1, as shown in Fig. 2, with a circuit of constant potentials, and let the contact-breaker above described, denoted by C, and the electro-

* Cantor lectures delivered before the Society of Arts

Digitized by Google

static voltmeter, V, be applied to determine the form of the current curve flowing into the primary coil, P, of the transformer. In order to delineate the form of the curve of primary potential difference, it is necessary to put across the primary terminals of the transformer a non-inductive resistance, R^2, which is divided in a definite ratio, so that by measuring a fraction, say 1-20, of the whole difference of potentials between the terminals of the primary circuit of the transformer we can determine the total potential difference. After much experimenting I succeeded in devising a form of resistance which is now before you, and which is very convenient for this purpose. It is called a resistance cage. It

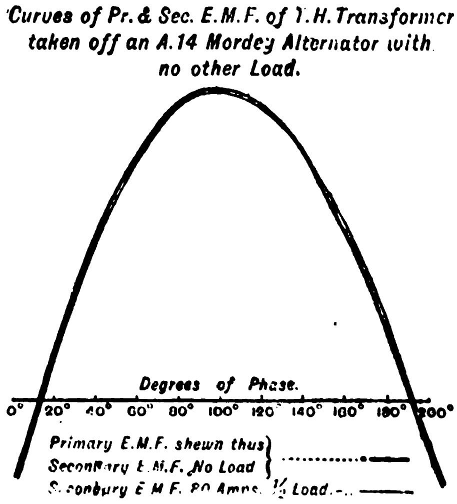

FIG. 19.

consists, as you see, of a series of brass rods held in a wooden frame, each rod carrying a pair of porcelain heads with porcelain pins on them (see Fig. 18), and these porcelain heads are kept pressed apart by a spring. Over the pins on these porcelain heads is wound, in zigzag fashion, a platinoid wire, so as to form a perfectly ventilated non-inductive resistance. Each of these resistances is adapted for withstanding 100 volts pressure, and carrying one-half or one ampere, and a series of 20 of these resistances can be put across the primary terminals of a transformer, and will withstand the pressure of 100 volts for as long as necessary. By measuring the fall of potential and delineating the periodic value of the difference of potential between the terminals of one cage, which forms one of a series of 20, we can delineate the whole difference of potential between the terminals of a transformer. In this way

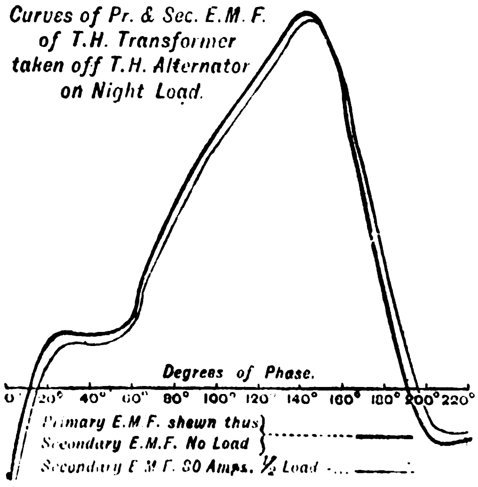

FIG. 20.

we can take curves of primary current and primary E.M.F. on the high-tension side of a transformer. In the next place we can perform the same operation on the secondary side of the transformer, and obtain the secondary terminal potential difference curve, and also, if the transformer is sending a secondary current, the secondary current curve for that transformer. When these experiments are carried out for any good closed-circuit transformer, and delineated in the form of a series of curves set in their proper relative position, which it is convenient to call a transformer diagram, we find the following results: In the first place, the curve of secondary potential difference is always an exact copy to a reduced scale of the curve of primary potential difference, and it is very nearly exactly in opposition to it in phase. This is shown in Fig. 19 and Fig. 20. Fig. 19 gives us the curves of primary and secondary E.M.F. of a Thomson-Houston transformer taken off a Mordey alternator. If the transformer is taken at no load, and if the curves of primary and secondary E.M.F. are drawn to such scale as to their maximum ordinates equal to one another, and if they are drawn on the same side of the axis then it is found that at no load the transformer curves exactly overlap one another. If the tranformer is partly or wholly loaded up on its secondary side, so as to cause it to send a secondary current, then the secondary E.M.F. is a little advanced in phase over the curve of primary E.M.F. as shown in Fig. 18. Fig. 20 shows the same thing for the same transformer taken off a Thomson-Houston alternator. Hence we see that the closed-circuit transformer acts like an electrical pantograph; it copies electrical potential difference, and the curve of secondary potential

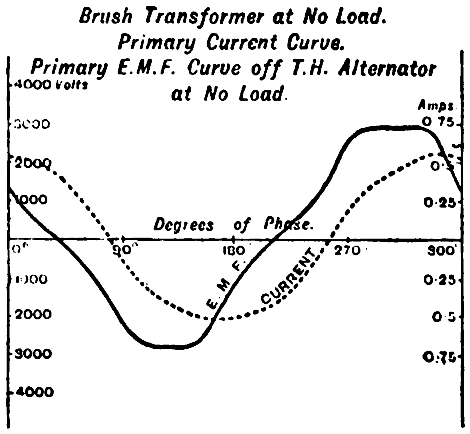

FIG. 21.

difference is always a nearly exact copy of the curve of primary potential difference; but to a reduced scale depending on what is called the transformation ratio of the transformer. On delineating the curve of primary current of the transformer when the transformer is taken at no load, as shown in Fig. 21, we see that the curve of primary current when the secondary circuit is open differs in phase from the curve of primary potential difference. It lags behind it, and the same thing is shown by reference to Fig. 14, where the curve of primary E.M.F. for another transformer taken off the same alternator is given. It will be seen that even if the same alternator is employed for the test, the curve of primary current at no load is not the same in form in the case of all transformers. The form of this primary current curve is governed by the nature of the iron employed in the core. We then notice that even in cases where the primary E.M.F. curve is more or less approximately a sine curve or simple periodic curve, the curve of primary current is always more irregular. Having in this manner delineated the curves

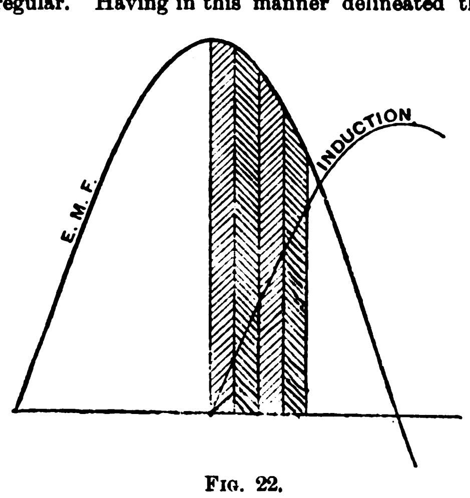

FIG. 22.

of primary current, primary E.M.F., and secondary current, we have then to determine the manner in which the induction in the core is varying with relation to these other varying quantities. We can draw out a curve of induction from the curve of a secondary E.M.F. in the following manner:

Since the secondary E.M.F. of the transformer at any instant is measured by the rate at which the magnetic induction linked with the secondary circuit is varying, we can construct the induction curve in the following way, as shown in Fig. 22. The curve marked E.M.F. represents a transformer secondary E.M.F. curve. The whole area of the curve is divided into two equal parts by a vertical line. Starting from this vertical line, half of the curve, say, the right-hand half, is divided up into narrow strips of equal area, which are represented by the

Digitized by Google

cross-hatched slips. The areas of these very narrow slips are then taken with the planimeter, and we set off, starting from the middle point of the time axis, the curve of induction by the following method. Starting from the middle point of the time line we set-off on the right-hand side of the first slip an ordinate which represents to some suitable scale the area of slip No. 1. On the right-hand bounding line of slip No. 2 we then set-off an ordinate equal to the same scale of the total areas of slips No. 1 and 2 together. On the right-hand bounding line of the third slip we then in the same way set-off an ordinate representing the total area of the first three slips, and so on. In that way we obtain points on a curve which represents what is called the time integral of the E.M.F. curve, and this is, therefore, the proper representation for the induction curve. In order to determine the scale to which this induction curve is drawn we must know what is the value of the maximum ordinate of the induction curve. This can be done in the following manner.

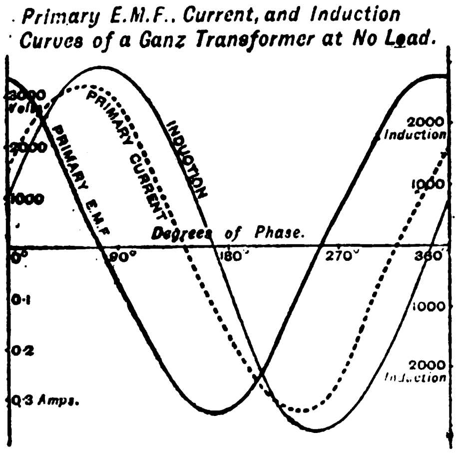

FIG. 23.

If B represents the induction in the core, S the cross-section of the core, N_2 the number of turns of the secondary circuit, n the frequency of the alternating current, and f the form-factor of the secondary circuit curve, then it can be shown that the root-mean-square value of the secondary E.M.F. is equal to $4 f . n . N_2 S B$, and hence, since the root-mean-square value of the secondary E.M.F. is immediately known from the delineated curve, and also its form-factor, we can easily calculate the value of B—that is, of the induction*—that is to say, in this manner not only can we thus delineate the curves of current and E.M.F., but also the induction, and represent them graphically on the same diagram. In Fig. 23 are shown the curves of primary E.M.F., primary current, and induction for a Ganz transformer taken at no load. The curve of induction can be determined in the above-described manner, not only from the curve of secondary E.M.F., but also from the curve of primary E.M.F.

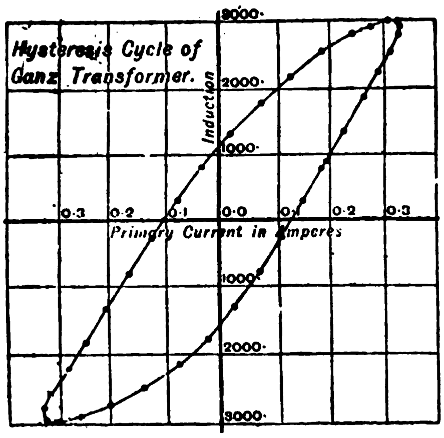

FIG. 24.

If this be done it is found that two curves of induction so obtained do not exactly coincide. The reason for this is the magnetic leakage of the transformer. This last term is best defined by saying that when the transformer is at work and sending a secondary current, the whole of the magnetic induction which is linked with the primary circuit is not linked with the secondary circuit. There is, as it were, an escape of induction from the secondary circuit which is called the magnetic leakage. In discussing in a later lecture the testing of a transformer we shall consider how this quantity can be measured. Having delineated the whole of these curves for a transformer, we are then in a position to draw a hysteresis diagram for the transformer. To do this, we have to set off in the form of a cyclic curve the variation of induction with magnetising force. It can easily be shown that if we construct a closed curve by setting off on a horizontal axis the different instantaneous values of the primary ampere-turns of a transformer on open secondary circuit taken at equal time intervals during the phase, and if corresponding with these we set off the vertical ordinates representing the total induction in webers in the core of the transformer corresponding to these different values of the ampere-turns, then the total area of that curve integrated in turns of a unit of area—one side of which represents a weber, and the other side of which represents an ampere-turn to the selected scale—will give us the value in joules of the energy wasted in the core of the transformer in one complete magnetic cycle, and in this manner we can determine from the transformer diagram the power wasted in watts in the core when the transformer is on open secondary circuit. This power is spoken of as the iron core loss in the transformer, and it can be determined directly from the transformer diagrams. In a later lecture we shall see how it can be more conveniently determined by one single direct measurement with the wattmeter. The diagram in Fig. 24 shows the hysteresis diagram thus determined for a Ganz transformer.

We have now briefly reviewed the chief actions going on in the transformer. Let us sum them up. If we apply to the terminals of a transformer a periodic E.M.F. varying according to any law, we find that we have a periodic current set up in the primary circuit which lags behind the primary E.M.F. when the transformer is an open secondary circuit, but which gradually comes into step with it in proportion as the transformer is loaded up. In good closed-circuit transformers a very small amount of loading up—even as much as one-fiftieth of full load—will suffice to bring the primary current curve into step with the primary E.M.F. curve. Secondly, we have a periodic magnetic induction in the core, which differs in phase, both from the primary current and the primary E.M.F., and it is found that this magnetic induction curve is always a more regular curve than the curve of primary E.M.F. When the curve of primary E.M.F. is approximately a simple periodic curve, then the curve of induction is more nearly a simple sine curve. Thirdly, we have a curve of secondary E.M.F. which is similar in form to, and exactly opposite in phase to, the curve of primary E.M.F. when the transformer is on open secondary circuit, or when it is sending a small secondary current into a non-inductive resistance. If the secondary circuit of the transformer is practically non-inductive, as it is when the transformer is working upon a load of incandescent lamps, then the curve of secondary current is always in step with the curve of secondary E.M.F., and can be deduced from it. Lastly, we have a curve deduced from the curve of induction and primary current of no load which give us the hysteresis curve of the transformer. The curve of primary current of no load is generally spoken of as the magnetising current, and the total power taken up in the iron core in watts is spoken of as the iron loss of the transformer.

* See "The Alternate-Current Transformer," vol. i. (new edition), p. 358.

LEGAL INTELLIGENCE.

QUESTION OF LIABILITY.

In the City of London Court, on Monday, before Mr. Commissioner Kerr, the case of the Cruto Incandescent Lamp Agency Limited, *v.* New and Mayne was heard. The plaintiff company, Dock House, Leadenhall-street, E.C., sought to recover the sum of £12. 3s. for electrical goods from the defendants, who are electrical engineers at Palace-chambers, Bridge-street, Westminster.

Mr. Bingley, counsel for the plaintiffs, said that the defendants had a branch office at Hull, and the plaintiffs received an order purporting to come from the defendants' Hull branch and signed by their manager (Mr. Fitzmorris). When the plaintiffs applied for payment of their account, they were told by the defendants in London that they had disposed of their Hull branch 12 months before to their late manager, and that if he had gone on using their paper, etc., it was not their (defendants') fault.

Mr. Whateley, defendants' counsel, said the defendants could not possibly be held liable for the acts of their manager after he had ceased to represent them, and after he had, in fact, taken over the business from them.

Evidence having been heard, **Mr. Commissioner Kerr** said the plaintiffs could not get over the fact that the defendants themselves had never ordered the goods which were being sued for. That being the case, there must be judgment for the defendants, with costs.

Verity's, Limited.—This is a new company, registered on July 9 by B. Verity, 39, Oakhurst-grove, Dulwich, S.E., with a capital of £2 000 in £1 shares, in order to carry on business as cycle manufacturers and electrical engineers in all or any of their respective branches. The Company is registered without articles of association.

COMPANIES' MEETINGS AND REPORTS.

ELECTRICAL POWER STORAGE COMPANY, LIMITED.

The ordinary general meeting of this Company was held on Thursday week at the offices, Great Winchester-street, Mr. J. Irving Courtenay presiding.

The **Chairman**, in moving the adoption of the report and accounts, stated that the directors were able to recommend the same dividend as that which was paid in the previous year—5 per cent. Full provision had been made for maintaining their buildings and plant. The quantity of their manufactures sold during the year showed an increase, in spite of the keen competition. It had given them much pleasure to have M. Camille A. Faure, to whose brilliant invention in 1881 secondary batteries owed their commercial existence, associated with this Company's manager, Mr. Frank King, with the result that, after long and exhaustive experiments in the Company's laboratory, extending over a year and a half, a reduction in weight in the battery of over 40 per cent. and a reduction in space of 45 per cent. had been achieved, and this without any sacrifice of stability. The importance of these improvements in connection especially with autocars, tramcars, and self-propelled vehicles generally could not be over-stated, and they had just come when most wanted by engineers and the public. He had read with some surprise the statement in a report of the committee of the Glasgow Corporation that the combined system of the overhead trolley and accumulators which had been installed at Hanover, in Germany, was in their opinion objectionable. In consequence of this statement he had taken some pains to get official information, and he had found that the results of the installation were so favourable that the directors of the Hanover Street Tramways had resolved to increase very considerably the size of the installation. The installation generally appeared to have given every satisfaction, and had fulfilled all the claims made upon it, and it was important to notice that the financial results as regarded the maintenance of accumulators had been exceedingly satisfactory. Moreover, the local authority, which in this case was the police authority, confirmed the great superiority of the arrangement of accumulator traction in the town of Hanover over any other system of electric traction. He moved the adoption of the report and the payment of the dividend mentioned.

Sir Daniel Cooper seconded the motion, which was carried unanimously.

A vote thanks was passed to the manager and staff for their services during the year, and a special compliment was paid to Mr. Frank King in reference to the secondary battery.

Mr. King briefly replied, and the rest of the business, which was purely formal, consisted of the re-election of a director and the auditors and a vote of thanks to the chairman for presiding.

INDIA RUBBER AND TELEGRAPH COMPANY.

The adjourned special meeting of the shareholders of the India Rubber, Gutta Percha, and Telegraph Works Company, Limited, was held on Tuesday at Cannon-street Hotel, Mr. Matthew Gray presiding. It will be remembered that at the Company's meeting on the 7th inst. it was proposed to make certain alterations in the articles of association, and after discussion it was decided to adjourn the matter for a fortnight to allow the shareholders further time to consider them. The new articles proposed were given in our issue of July 10.

The **Chairman** now formally proposed and **Mr. W. S. Silver** seconded the adoption of the new articles.

Mr. Cochrane objected to the resolution on the ground that the existing articles made it compulsory on the directors to furnish the shareholders with fuller information in the accounts than they would have to give under the new articles, and asked on what ground the auditors suggested the proposed alterations. Fuller information had been repeatedly asked for from his (the shareholders') side of the table, and had been always refused. Items that should have been by the articles stated separately had been put together. Had they (the shareholders) been more sharp, they could have claimed the information they asked for as a matter of right under the articles. He (Mr. Cochrane) would like to hear from the auditor what the reasons for the alterations were.

Mr. Clarke (Messrs. Turquand, Youngs, and Co.) stated that personally he had audited the Company's accounts for only three years. He drew attention some time ago to the fact that the accounts were not quite in accordance with the articles, but it was considered that the words "as near thereto as circumstances admit" covered the case." As the result of further consideration, however, and on its being explained to him that to give the full details required by the articles would be prejudicial to the Company, he suggested that the articles should be altered as now proposed. He did not think for a moment that any objection would be raised to the proposals. The articles were in an obsolete and out-of date form. He (himself) had taken the same course in all the companies with which he was connected, and similar alterations had had the approval of Mr. Swinfen Eady. He (Mr. Clarke) had not at the time imagined that there would be any opposition to the proposal.

The **Chairman** said the Company was a trading one, and was bound to give tenders for supplying a great deal of the materials they manufactured. It was highly desirable that those tenders should not be known to competing firms. Some of their competitors had actually bought a few shares in their Company, and he could only imagine it was for the purpose of acquiring information. It was therefore desirable that while the auditor had full inspection of the accounts, the articles should not compel him to include in the published statement information that might be injurious to the interests of the Company. Moreover, the articles as they stood required a separation of the profits on different work, which was practically impossible.

The resolutions for the amended articles were carried, with one dissentient. There will have to be a formal meeting to confirm them.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY, LIMITED.

The half-yearly general meeting of this Company was held on Tuesday at the offices, 38, Old Broad-street, Admiral Sir G. H. Richards presiding.

The **Chairman**, after referring to the death of Sir John Pender, who was the first chairman of this Company, said that they had no official business to transact, nor had the directors any accounts to place before the shareholders. Although they had not carried out any large contracts so far this year they had received orders from various companies and governments for several hundreds of miles of cable, a good deal of which had been completed. But, perhaps, the most important operations they had performed had been the repairing of different cables, all of which had been successfully accomplished. The principal of these had been the repairs to the French Telegraph Company's cable between Brest and New York. Although the Board were desirous of giving all the information they could to the shareholders they felt that it would be unwise to allude to any contracts of which they were not absolutely in possession, for experience had shown that there were always delays and disappointments in matters of this kind, especially when dealing with foreign countries. They proposed to pay the usual interim dividend of 12s. per share, being at the rate of 10 per cent. per annum.

No resolution was submitted.

BRITANNIA MOTOR CARRIAGE COMPANY, LIMITED.

The statutory general meeting of this Company was held on Tuesday at Winchester House, E.C., the Hon. J. H H. Berkeley (the chairman of the Company) presiding.

In the course of his speech to the shareholders, the **Chairman** referred to the prospectus, which did not state the nature of the motor. It could not, for various reasons, be either a water, steam, oil, benzine, or spring-driven motor, and therefore "any intelligent investor, seeing that it would not be driven by any of these powers, and understanding there is no such thing as perpetual motion, would know that there was only one other power available—viz., electricity." After mentioning that the motor had been on view in Tottenham Court-road, the Chairman continued: "Exception was taken that no reference was made that a battery would be necessary, and that a battery would add very considerably to the weight. Well, we were only advertising a motor; we had nothing to do with advertising a battery. We were pledged to no particular sort of battery, our intention being to use any battery which was most suitable for our motor, for we claim it can be driven equally well either with a secondary or primary battery, and in some instances no battery would be required, such as when the motor is on a tramcar, or for stationary work." The weight of the motor was about 100lb., and the additional weight of the battery for the horse-power employed would not be more than 518lb., what their 2-h p. motor was asked to do was one fifth of what the omnibus horses do in London; therefore the omission in stating that a battery would have to be employed was not of very material importance. Another criticism was that the motor would constantly require to be recharged, and the accumulators could not be charged in country places. Anyone living in a country place where there was not a supply of electricity would not use an accumulator, but a primary battery, which was quite as applicable to their motor. Anyone who applied for shares in a company exploiting a patent must be aware that he was dealing in a speculative company. They had had many offers for the motor from those who had seen it. From one well-known seaside town alone they had an offer to take a very large number. These were offers from hard headed business men who, having seen the motor, believed it would be put to practical use in competition with other motors that are being offered. In reply to a Shareholder who enquired as to primary batteries, the Chairman subsequently said, "at the present moment we have a primary battery offered to us which, if it fulfils all it is said to do, will answer every expectation. I do not think it would be desirable at the present moment to disclose any of the negotiations. It is stated here that the secondary battery would run from 60 to 100 miles. The inventor, Mr. Sherrin, has made a statutory declaration that with a battery and motor such as we have had he went 64 miles."

There was no resolution before the meeting, but a vote of thanks to the chairman and directors was proposed and carried.

EASTERN TELEGRAPH COMPANY, LIMITED.

The report of the directors of this Company for the half-year ended March 31 states that the revenue for the period amounted to £466,093, from which are deducted £99,152 for the ordinary expenses, and £33 956 for expenditure relating to repairs and renewals of cables, etc., during the half-year. After providing

Digitized by Google

£4,413 for depreciation, £389 due to revaluation of currency assets, £5,806 for income tax, and transferring £20,000 to the fire insurance fund, there remains a balance of £302,377, to which is added £49,353 brought forward, making a total available balance of £351,730. From this balance there have been paid — interest on debentures and debenture stock £29,282, dividend on preference shares £20,296, an interim dividend of 2s. 6d. per share on the ordinary shares £50,000, leaving a balance of £252,152, out of which the directors have placed £10,000 to the reserve fund for maintenance ships and £125 000 to the general reserve fund. The directors now recommend the declaration of a final dividend for the year of 2s. 6d. per share and a bonus of 3s. per share, amounting together to £110,000, both payable on 23rd inst., free of income tax, and making with the three previous payments, a total distribution of 13s. per share, or 6½ per cent. for the year on the ordinary shares, and leaving £7,152 to be carried forward. The directors have appointed as chairman of the Company, in place of the late Sir John Pender, the Marquis of Tweeddale, who has been vice-chairman since 1874. They have also appointed the present managing director (Mr. J. Denison Pender) as vice-chairman, and Mr. C. W. Earle a director of the Company.

The ordinary general meeting of this Company took place yesterday (Thursday) at Winchester House E.C., the Marquis of Tweeddale presiding. Resolutions for the dividend, etc, were carried on the motion of the Chairman, seconded by Mr. J. D. Pender. There was also a motion of condolence with the family of the late Sir John D. Pender, which was proposed by Mr. J. Gibbs and seconded by Mr. H. Burcher.

CITY AND SOUTH LONDON RAILWAY COMPANY.

Directors: Charles Grey Mott, Esq. (chairman), Harrow Weald, Middlesex; Charles Seymour Grenfell, Esq., Elibank, Taplow; Sampson Hanbury, Esq., Wyvenhoe Park, near Colchester; S. Barclay Heward, Esq., 96, Ashley-gardens, Westminster; Edwin Tate, Esq., 21, Mincing-lane E.C.

Report of the directors, with abstract of accounts for the half-year ending June 30, 1896, to be submitted to the half-yearly ordinary general meeting of the Company, to be held at Winchester House, Old Broad-street, E.C, on Tuesday, July 28, 1896, at 12 noon:

The receipts from all sources for the past half-year have amounted to £24,910. 18s. 9d., and the cost of working has been £15,001. 17s. 10d., leaving a profit of £9,909. 0s. 11d. Inclusive of the balance brought forward from December 31 last, the net revenue account shows an aggregate total of £11,158. 5s. 2d. After making provision for the debenture and debenture stock interest, a balance remains available for dividend of £7,499. 1s 8d. Out of this sum your directors recommend that the full dividend of 5 per cent. per annum be paid on the preference shares, and that a dividend at the rate of 1⅜ per cent. per annum be paid upon the consolidated ordinary stock, leaving a balance of £1,072. 5s 6d. to be carried forward to the next account. The following table shows the number of passenger, exclusive of season-ticket holders, carried since the opening of the railway in each half-year:

Half-year ended	Number of passengers (exclusive of season-ticket holders).	Receipts (including season tickets).		
Dec. 31, 1890 (11 days)	165 000	£1 568	3	9
June 30, 1891	2 412,343	19,403	6	9
Dec. 31, 1891	2,749,055	19,798	16	6
June 30, 1892	2,813,162	20,931	4	2
Dec. 31, 1892	3,117,602	22,002	17	5
June 30, 1893	3,146,656	22 458	6	9
Dec. 31, 1893	3,093,351	22,067	14	10
June 30, 1894	3,383,154	23,564	10	6
Dec. 31, 1894	3,275 649	23 540	12	4
June 30, 1895	3,113,199	23 711	5	8
Dec. 31, 1895	3,172 438	23 780	3	7
June 30, 1896	3 192,672	24,021	13	0
Total since the opening of the line	33 634,281	£246,848	15	3

The exceptionally mild winter and the extremely fine weather since experienced have, there can be no doubt, militated against the traffic of the line, and it is satisfactory that, in spite of these adverse conditions, the returns for the half-year show an increase both in the number of passengers carried and in the amount of receipts. The alterations at the City station have proved, as was anticipated, of considerable advantage in coping with the traffic in the busy hours of the day. The new coaches, and the locomotive constructed in the Company's own shops, are now in use with satisfactory results. The generating plant, locomotives, and rolling-stock have been well maintained, and are in good working order and efficiency. During the half-year, a further sum of £8,400 5 per cent. terminable mortgage bonds has been paid off. The erection of the condensing plant is now proceeding rapidly. This work has been somewhat delayed through the anxiety of your directors to avail themselves of the latest improvements with the view of obtaining as perfect an apparatus as possible. Active steps are now in progress for the acquisition of the sites required for the stations at London Bridge and Finsbury-pavement, and tenders have been invited for the construction of the works. Acting under the authority given by the proprietors at the last half-yearly meeting, the 20,000 5 per cent. perpetual preference shares then authorised have all been placed at a considerable premium, it being stipulated that no dividend shall accrue upon those shares until after January 1, 1899, by which time it is expected the extension will be finished and open for traffic. The Bill for the extension of time for the completion of the works authorised by the Company's Act, 1893 (Islington Extensions) has been considerably delayed owing to the opposition to the powers granted by the original Act for the acquisition of the site of St. Mary Woolnoth Church. In the first instance the rector and churchwardens of that church desired that the building should not be removed, and upon their opposition the House of Commons Committee inserted a clause in the Bill for the preservation of the fabric of the church, but when the Bill came before the Committee of the House of Lords, the rector and churchwardens informed that committee that, under the circumstances, they preferred that the church should be pulled down, and the committee thereupon struck out the clause inserted in the Commons. It is hoped that the Bill will now meet with no further opposition during its remaining stages,

CROMPTON AND CO., LIMITED.

Directors: John Trotter, Esq., chairman; Rookes Evelyn Bell Crompton, Esq., and John Francis Albright, Esq, managing directors; Bernard Gibson, Esq.; Carleton F. Tufnell, Esq.

Eighth report of the directors to be presented at the annual general meeting of the shareholders to be held at the City Terminus Hotel, Cannon-street, E.C, on Monday, July 27, 1896, at 3 p.m.:

By the fire at the Chelmsford works of the Company as reported by circular to the shareholders in November last the offices of the Company were, with the whole of their contents, including all the books of account there, and drawings, utterly destroyed, and as a consequence the directors are unable to present to the shareholders the usual statement of profit and loss for the past year. The directors have thought it best to have a complete revaluation made of all the Company's property and assets as at March 31 last, and the statement so prepared they now submit to the shareholders. The loss of property by the fire has been made good by the insurance companies, and the amount has been partly reinvested in similar assets, leaving a balance of £26 585 which has been placed on deposit to be applied only in restoration. The directors, owing to the growth of the business and the demand of the insurance companies that the generating station for the lighting of Chelmsford should be detached from the manufactory, have decided, after careful consideration, that it is advisable to construct new works upon a more convenient site, and they have accordingly purchased nine acres of freehold ground adjoining the railway at Chelmsford, and contracts have been let for the erection of commodious works with a siding on to the railway. The directors believe that these works, situated on the main line of railway and fitted with all modern appliances, will place the Company in a far more favourable position for manufacturing economically and rapidly than it could ever have attained at the old site. The Chelmsford Electric Lighting Company, Limited, is making very satisfactory progress. The station for generating the electrical energy has hitherto formed part of the manufacturing premises of this Company, and a fixed charge per unit has been made for current supplied to the lighting company. It is now, however, proposed that the electricity station which is being re-erected and

Digitized by Google

equipped after the fire shall be sold outright to the lighting company, which will thenceforward carry on its own business independently. Although the insurance companies have paid for the property actually destroyed by the fire, the consequential damage to the Company has been very great. Owing to the serious interruption to the business, and the greatly increased costs of manufacturing in temporary premises since the fire, a heavy loss has been incurred by the Company. The statement now presented shows a balance of £10,051. 0s. 11d. to the debit of the revenue account, to which must be added £1,000 as a provision for doubtful debts; and as this loss is entirely owing to the exceptional circumstance of the fire, the directors propose to place the amount to a suspense account. It is with much pleasure the directors have to report that the order book of the Company is so full that a larger number of men are employed at Chelmsford than has ever been necessary before, and the prospects for the future are most satisfactory and encouraging. The directors regret that, as announced at the general meeting last year, Viscount Emlyn has retired from the position of chairman of the company in consequence of his having been appointed chairman of the Great Western Railway. The Board have elected Mr. John Trotter to fill the vacancy thus caused, and a resolution will be submitted confirming this appointment. In accordance with the articles of association Mr. Carleton F. Tufnell retires from the Board of directors by rotation, but offers himself for re election. The auditors, Messrs. J. H. Duncan and Co., also offer themselves for re-election.

NATIONAL TELEPHONE COMPANY, LIMITED.

The report of the directors of this Company for the half-year ended June 30 states that the income accrued in respect of the business of the half-year amounts to £429,681, as compared with £396,385 for the corresponding period of 1895, being an increase of £33,295. The working expenses amount to £226,250, as against £207,628, being an increase of £18 622. The net result for the half-year (after deducting the Post Office royalties, amounting to £38,958) is a profit balance of £164,472, as compared with £152,322 for the corresponding period last year, being an increase of £12,150. The rentals carried forward for unexpired terms of running contracts amount to £438,322, an increase of £47,343 over the corresponding period in 1895. Out of the available balance of £136,612 the Board will recommend the payment of a dividend at the rate of 6 per cent. per annum, less income tax, on the first and second preference shares; 5 per cent. per annum, less income tax, on the third preference shares; and 5 per cent. per annum, free of income tax, on the ordinary shares. The Board also propose to transfer £35,000 to reserve, and to carry forward £17,133. The sum of £248,537 has been expended upon additional exchange and private lines erected during the half-year. A not inconsiderable proportion of this outlay is attributable to the substitution of metallic circuits for single lines and the construction of underground work in lieu of overhead wires; both these sources of expenditure having become necessary to ensure greater efficiency in the service to subscribers in the more important and crowded centres. In accordance with the agreement arrived at between the Post Office and the Board, the trunk lines from time to time erected by the Company were surrendered to the State on April 4 last in consideration, amongst other things, of the payment on the same date of their value as ascertained and fixed by experts after an elaborate and prolonged enquiry. This transfer, separating the conduct of the trunk business from the working of the local exchanges in the numerous areas assigned to the company, has naturally involved some inconvenience in connection with the "through" telephone business of the country, but as the authorities of the Post Office and the officers of the Company are loyally co operating with the object of securing to the public the most efficient service possible, it is hoped that the inconvenience adverted to may be speedily terminated. The Board have long had under consideration the advisability and necessity of establishing a pension fund for the benefit of the officers, clerks, and others in the service of the Company. The Board have had the advantage of the experience and advice of an eminent actuary familiar with the principles and details upon which many such funds have been founded, and are now working successfully, and felt that they would have the support and sympathy of the shareholders in dealing with the matter in a generous spirit, by making the annual contribution of the Company to the fund sufficient to ensure its stability and to provide for the case of those officers and servants who, having already been in the service some years, would otherwise be placed at great disadvantage in realising the benefits of the fund in comparison with new and younger members of the staff.

The general meeting takes place on the 30th inst.

DIRECT UNITED STATES CABLE COMPANY, LIMITED.

The report of the directors of this Company for the six months ending June 30 states that the half year's revenue, after deducting out-payments, amounted to £42,457, as compared with £37,653 for the corresponding period of 1895, being an increase of £4,803. The working expenses for the same period, including income tax, but exclusive of cost of repairs of cables, amounted to £19 692, leaving a balance of £22,764 as the net profit of the half-year, making, with £4,149 brought forward, a total of £26,913. For the corresponding period of 1895, the working expenses and other payments amounted to £18,909. Three quarterly interim dividends, amounting to £19,731 have been declared and paid during the financial year, and a final payment of 2s. 6d. per share is now proposed, making, with the three interim dividends, 2¼ per cent. for the year, being a total distribution of £27,319. After transferring £7,500 to the reserve fund, the balance of £4,235 is proposed to be carried forward. The directors have appointed Mr. E. M. Underdown, Q.C., to be chairman, in place of the late Sir John Pender. The cable repairs in progress in December last were satisfactorily completed early in January at a further cost, including new cable inserted, of £8,244, which has been debited to the reserve fund account, the balance of which, with the addition of interest, realised profit, and amount transferred from revenue account, now stands at £313,969.

The general meeting takes place on the 28th inst.

ANGLO-AMERICAN TELEGRAPH COMPANY, LIMITED.

The report of the directors of this Company for the past half-year states that the total receipts from January 1 to June 30, including the balance of £794 brought forward from the last account, amounted to £154,832 The traffic receipts show an increase of £11,917, as compared with the corresponding period of last year. The total expenses of the half-year, including the repair of cables, etc., as shown by the revenue account, amounted to £57,029, being an increase of £1,645. The directors, under the powers conferred upon them by the articles of association, have, before declaring the net profits, set apart the sum of £12,000 to the renewal fund, leaving a balance of £85,803. One quarterly interim dividend of 12s per cent. on the ordinary and of £1. 4s. per cent. on the preferred stock was paid on May 1 last, absorbing £42 000, and a second quarterly dividend of 12s. per cent. on the ordinary and £1. 4s. per cent. on the preferred stock, amounting to £42 000, will be paid on August 1, leaving a balance of £1,803 to be carried forward to the next account. The general meeting takes place to-day (Friday).

GLOBE TELEGRAPH AND TRUST COMPANY, LIMITED.

The report of the directors of the Globe Telegraph and Trust Company, Limited, for the year ended July 18 states that the net revenue for the year, after deduction of expenses, amounts to £185,223, and makes, with the balance of £1,238 brought

Digitized by Google

forward, a total of £186,461. From this amount there has been distributed the sum of £125,614 in interim dividends, leaving an available balance of £60,847. The directors recommend the payment of a final dividend for the year of 3s. per share on the preference shares, and of 3s. 9d. per share on the ordinary shares, making with previous distributions a total dividend for the year of 6 per cent., less income tax upon the preference and 4½ per cent. net (against 4½ per cent. for the preceding year) upon the ordinary shares, leaving a balance of £948 to be carried forward. The directors have deemed it advisable in future to pay the interim dividends on October 31, January 31, and April 30 in each year, the date of the final dividend remaining unchanged. Since the last meeting the remainder of the money resulting from the paying off of the Direct Spanish Telegraph Company's 6 per cent. debentures has been reinvested. The directors have appointed the Marquis of Tweeddale as chairman, in place of the late Sir John Pender. The shareholders' meeting is fixed for the 28th inst.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Odessa.—The Municipal Authorities will receive tenders up to August 13 for street electric lighting and for the lighting of the new prison.

Nava del Rey (Spain).—The Municipality are open to receive tenders up to August 28 for the electric lighting of Nava del Rey for a period of 20 years.

Brussels.—Tenders are requested by July 26 for repairs and renewals of lightning conductors for the local administration Applications to rue des Augustins 17, Brussels. The amount is about £400.

Mons.—Tenders are required for the construction of an electric generating station building for the Tournai Asylum. Particulars at Brussels, rue des Augustins 17, and tenders will be received up to August 3.

Vich (Spain).—The contract will be allotted by the municipal authorities of Vich on August 17 for the electric lighting of the town for 10 years from June, 1897. The annual payment proposed is about £800.

Halifax.—Firms desiring to tender for the electric lighting and hoists at the new infirmary to be built for the Guardians of the Halifax Union must apply before August 13 to the architects, Messrs. Horsfall and Williams, George-street and deposit two guineas with the Clerk to the Guardians, Union Offices, Halifax.

London, E.C.—Messrs. Hazell, Watson and Viney, Limited, invite offers for a motor van, suitable for carrying large quantities of paper between Aylesbury and London (30 miles). High speed not essential. Address offers, marked "Motor Van Tender," care of Hazell, Watson, and Viney, Limited, 1, Creed-lane, London, E.C.

Hapton (Padiham, Lancs.).—Tenders are wanted for lighting Hapton township with electricity from September 1, 1896, to April 30, 1897, for the Parish Council. Endorsed tenders should be sent to Mr. E. O'Shaughnessy, clerk, St. Anne's-terrace, Padiham, by August 3. Full particulars can be obtained on application to the clerk at that address.

Simla (India).—The Municipality is inviting tenders for lighting by electric light for a term of years the principal thoroughfares and buildings belonging to the Municipality. Tenders must be submitted by September 1 next. Should any proposal be accepted, the Municipality will afford the successful tenderer all facilities to extend the system of lighting to private houses.

Cologne.—Tenders are required by the Municipal Authorities for the construction and working of electric tramways in the city of Cologne to an aggregate length of 20·3 kilometres (12¼ miles). Specifications, plans, and particulars are obtainable for 10 marks (10s.) from der Registrateur B, des Oberbürgermeisteramt, Köln, Germany, and tenders must be in by November 6.

Madras.—Tenders are invited for the lighting by electricity of Government House, Madras, including the banqueting-hall and aide-de-camps' bungalow, and also for the lighting of Government House, Guindy, including the military secretary's bungalow. For particulars application must be made to the consulting architect to the Government, Chepank, Madras. Tenders will be opened on November 11, 1896.

Blackpool.—The Corporation require tenders for the supply of coal and oil to the electricity department. Specifications may be obtained on application to Mr Robt C. Quin, borough electrical engineer, Corporation Electricity Works, West Caroline street, Blackpool, and sealed tenders must be delivered at the electricity works not later than 10 a.m. on 27th inst., addressed to the Chairman of the Electric Lighting Committee, and endorsed "Tender for Coal" and "Tender for Oils" respectively.

San Juan (Puerto Rico).—H.M. Secretary of State for Foreign Affairs has received from H.M. ambassador at Madrid a copy of a Spanish Royal Order which has appeared in the *Gazette* inviting tenders for the construction and working of a telephone system in San Juan de Puerto Rico. A deposit of 800dol. must accompany each tender, which will be considered on August 10. The copy of the Royal Order may be seen on application to the Commercial Department of the Foreign Office between the hours of 11 and 6.

Voghera (Italy).—In view of the expiration of their contract with the local gas company in 1898, the municipal authorities of Voghera are desirous of receiving during the present year propositions for the lighting of the town either by the electric light or a mixed system of gas and electricity. The population is 16,000. Application should be made to L'Administrazione Comunale, Voghera, who will give all particulars necessary.

Mexico.—The municipal authorities of the city of Mexico are prepared to receive proposals for the street lighting by incandescent lamps for a period of eight years Tenders should be sent in by August 31. The Secretary of State for Foreign Affairs has received from the British Consul at Mexico a pamphlet issued by the Municipal Council of the city containing particulars as to the tenders, and this may be seen on application to the Commercial Department of the Foreign Office between the hours of 11 and 6.

Southampton.—The Harbour Board invite tenders for the construction and erection of four electric cranes and accessories, and also for alterations to gantry of an existing crane, on the Town Quay, Southampton. Specification, with two general drawings attached, may be obtained on and after 20th inst. from Mr. A. H. Skelton, clerk, Town Quay, Southampton, upon payment of £3. 3s , which will not be returned, and further detailed plans may be seen at the office of the electrical engineer, Mr. J. G. W. Aldridge, 9, Victoria-street, Westminster, S.W. Sealed tenders, marked "Tenders for Electric Cranes," should be sent to the clerk by August 10.

Hull.—Tenders are required by the Electric Lighting Committee for the supply of best South Yorkshire hard steam doubled-screened nuts for 12 months ending June 31, 1897, in accordance with the conditions set forth in the form of tender, which may be obtained at the Electric Lighting Offices, Dagger-lane. The contractor will have to enter into the usual form of contract required by the Corporation. Tenders, endorsed "Double-Screened Nuts for Electric Lighting Station," to be sent, under seal, to the chairman of the Electric Lighting Committee, Town Hall, by noon on 30th inst. Mr. A. S. Barnard, borough electrical engineer, Electric Lighting Station, Dagger-lane.

Mile End (London).—Tenders are wanted for the supply and erection of electrical plant, laying down electric mains, and wiring, for lighting premises in Bancroft-road, London, E , by electricity, for the Guardians of Mile End Old Town. Plans may be seen, specifications and full particulars obtained from Mr. C. F. Burden, architect to the Guardians, at his office on the premises, between 10 a.m. and 4 p.m., on production of a receipt from Mr. William Thacker, clerk, Bancroft road, London, E , of the deposit of a £5 Bank of England note, which will be returned on receipt by the Guardians of a bona fide tender, accompanied with such specification. The acceptance of a tender will be subject to the Local Government Board's approval of the scheme, etc. Tenders must be delivered by noon on 30th inst.

Kingston (Jamaica).—The Colonial Government invite electric tramway contractors willing to undertake the establishment and working of a system of rapid transit to send in applications for the grant of a license by the Governor in Privy Council under the Tramways Law, 1895. In all applications the principal questions to which attention should be directed are the following : (*a*) the amount of capital which the applicants are prepared to subscribe ; (*b*) the system which it is proposed to establish ; (*c*) the mileage of lines to be laid ; (*d*) the fares to be charged ; (*e*) the frequency of the service ; (*f*) the length of the license required by applicants ; (*g*) the guarantee which the applicants offer for the satisfactory performance on their part of any obligations devolving on them. Plans of the city of Kingston and part of the parish of St. Andrew, showing the routes on which the present tramway lines are laid, and copies of the law under which licenses are granted and of the rules made thereunder by the Governor in Privy Council, may be seen at the office of the Crown Agents for the Colonies, Downing-street, London, S.W. All applications must be delivered not later than July 31, 1896, in a sealed packet, marked on the outside "Application for Tramway License," to the clerk of the Privy Council, Kingston, Jamaica. Kingston has its principal means of transit at present supplied by the Jamaica Street Car Company by horse tramcars, the entire length of lines laid being about 12 miles. The concession granted by the Legislature of the island to the Jamaica Street Car Company will shortly expire.

RESULTS OF TENDERS.

Harrogate.—The Town Council have accepted the tender of Mr. J. Stephenson for the construction of a feed-water reservoir at the generating station.

Logan (Utah).—The contract for lighting the city by electricity has been obtained by the Hercules Power Company. By the terms of the contract the company agree to run 25 street lights of 1,200 c.p , with 16 incandescent lamps for inside use, at about £190 a year, the contract to be for two years, and the company to have the city's plant for the consideration of one dollar a year The Council could not make the undertaking pay.

Catalogues.—We have received from Messrs. C. W. Treacher and Co., of 165, Queen Victoria-street, E.C., their catalogues of telephones and bells, and of electric lighting material and apparatus. We hope to notice these catalogues at greater length shortly. We have also received, and reserve for further notice, Messrs. Rosling and Appleby's catalogue of dynamos, motors, and electrical machinery. Mr. F. C. Allsop's catalogue of electrical instruments must be similarly reserved.

Digitized by Google

BUSINESS NOTES.

Dover.—The Lord Warden Hotel has been fitted throughout with electric lights and lifts.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,762

West India and Panama Telegraph Company.—For the two weeks ended July 15 the receipts were £1,181.

Precautions Against Fire.—Messrs. Merryweather have just fitted hydrants, hose and other appliances at the St. Mary (Islington) and Chelsea electricity supply central stations.

Bucklow.—The Altrincham Electric Supply Company have given notice that they are about to break up about 200 yards of road for the purpose of laying down further mains at Bucklow.

Ayr.—Extensions of the electric lighting have been decided upon by the Town Council to Seafield at a cost of £264. 13s. 9d , and along Carrick-road, Broomfield road, and Racecourse View-road at a cost of £309. 7s. 6d.

Southwark (London).—The electric light is being installed into St. George's Cathedral and the work has been entrusted to Messrs. Fred. A. Donnison, Berlyn, Evans, and Co., of 116, Great Portland street, W.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending July 19 amounted to £1,267, as compared with £1,226 in the corresponding week of the previous year, being an increase of £41.

Govan.—The Burgh Commissioners have granted permission to Messrs. Simpson and Wilson, engineers of the subway, to erect an electric lamp at the corner of Paisley-road and Cessnock-street as a guide to their station in that quarter.

Bristol Tramways and Carriage Company, Limited.—The traffic returns for the week ending July 17 were £2,497. 15s. 6d., compared with £2,009. 9s. for the corresponding period of last year, being an increase of £488 6s. 6d.

Glover and Co.—The annual outing of the employés of Messrs. F. A. Glover and Co , of 97, Queen Victoria-street, E C , took place on Saturday last at Margate. The dinner was at the Margate Hotel Metropole, and Mr. F. A Glover presided.

Dublin.—At a meeting of the shareholders of the Dublin United Tramway Company the formal resolution has been passed authorising the purchase of the electric system of the Southern District Tramways Company for a sum of £273,000.

St. Pancras (London).—It has been proposed that the Baths and Wash-houses Committee should consider the advisability of installing the electric light at the baths and wash-houses, current to be priced at 5d. per unit as though for public street-lighting.

Chester.—Mains are now being laid in Bridge-street, Grosvenor-street, Pepper-street, St. John's-street, Eastgate-street, Foregate-street, Northgate-street, Town Hall-square, Watergate-street, and Nicholas-street. The price of current will be 6d. per unit.

Walsall.—At the monthly Town Council meeting the Town Clerk read a memorial signed by 75 tradesmen, etc , in favour of lighting High-street and Digbeth with the electric light. The memorial was referred to the Streets Committee for consideration.

Victoria (British Columbia).—The Consolidated Electric Railway Company has purchased the electric railway lines in this city, which were sold by auction recently. The company is an English syndicate, and owns the Nanaimo, Vancouver, New Westminster, and Victoria electric railways.

City and South London Railway.—The returns for the week ended July 19 were £857, compared with £831 for the corresponding period of last year, being an increase of £26. The total receipts for the half-year 1896 were £2,675, compared with £2,594 last year, being an increase of £81.

Glasgow.—It has been stated that the Corporation have practically decided to give the overhead electric traction system a trial on a small portion of their tramway system. No formal pronouncement has been made by the committee, but it is understood that this course will probably be adopted.

Eastern Extension, Australasia, and China Telegraph Company.—At a meeting of the Company on Wednesday, the Marquis of Tweeddale was appointed chairman of the Company in succession to the late Sir John Pender. Mr. F. E. Hesse was at the same time appointed manager as well as secretary.

Kirkcaldy.—At a meeting of the Town Council a report by Prof. Kennedy on the introduction of the electric light was considered. It showed that the new light could be conveniently introduced to Kirkcaldy at a cost of £20,000. It was agreed to remit the matter to a committee for recommendation.

Dover.—The Town Council have decided to await the report of the committee on the Rouen tramways before referring it to the surveyor to prepare plans for the tramways to be constructed and report on the system of traction to be adopted. The matter will come before the Council again at the next meeting.

D.P. Accumulators.—We have received from the D.P. Battery Company, of 66, Victoria-street, S W , a price list of the storage batteries. The list is headed with the statement that there are "eight miles of the cells in daily use." A number of testimonials from electrical engineers and private users are appended.

Swansea.—The Town Council have decided, instead of confining it to two local firms, to put the supply of an electric lighting installation for the market out to tender. Mr. Manville is the consulting engineer. The "triple scheme"—lighting, tramways and destructor—is still under consideration, with every prospect of adoption.

Broughton Moor (Cumberland).—Messrs. R. Wilson and Sons, of Broughton Grange, the owners, have commenced to put down plant at their collieries with a view to the works being lighted by electricity. The necessary machinery has arrived, and it is proposed to light the engine-rooms on the surface and the underground main roads.

Wellington.—At a special meeting of the Urban District Council it was decided that the Council, having considered the tender of the Brush Electric Lighting Company for lighting the town by electricity, should have an interview with their engineer with the view to the possibility of lighting the town by electricity in 10 months' time.

Halifax.—The new infirmary and market to be opened this week has been fitted with electric light, bells, and telephones. The contractors for the work were Messrs. Ullathorne and Hartley, Halifax and Bradford, and Messrs S J. Waring and Son, Limited, Manchester ; and for the dynamo and engine, Messrs. Greenwood and Batley, Limited, secured the contract.

Newington (London).—The members of that alliterative body, the Society for the Promotion of Practical Progress, connected with Murphy Memorial Hall, Newington, have been discussing the introduction of the electric light into the parish. Alderman Hubbard, of the London County Council, addressed them, but they do not seem to have come to any resolution or decision.

Bournemouth.—At a meeting of the Town Council the Roads Committee stated that at their meeting a letter from the provincial superintendent of the National Telephone Company was read, enclosing plan of proposed underground works, and they (the committee) recommended the surveyor be instructed to report with fuller details than he has at present. The motion was adopted.

Paisley.—The Town Council, in committee, have selected the the following as a "short leet" for selection for the position of resident electrical engineer : Mr. Bell, Manchester ; Mr. Christie, Londonderry ; Mr. Cooper, Blackpool ; Mr. Pilling, Bolton ; Mr. Teague, Coatbridge ; Mr. Pender and Mr. Anderson, Paisley. The salary is £200, and 61 applications were sent in to the Council.

British Motor Syndicate, Limited.—An extraordinary general meeting of the shareholders of the British Motor Syndicate, Limited, has authorised an increase of the capital of the Company to £1,000,000 by the creation of 850,000 shares of £1 each, and confirmed the action of the directors in purchasing patents and altering the name of the Company to the British Motor Company, Limited.

Westminster.—The order for the electric lighting of the National Gallery of British Art, now being built on the site of the Millbank Prison by Mr. Tate, has been placed in the hands of Messrs. Drake and Gorham. Mr. C. N. Russell, whose agreement with the London and Lancashire Electric Company has terminated, has joined Messrs. Drake and Gorham's staff, and is personally supervising the work.

New Company.—The Morley Fletcher Wave-Power System, Limited, which was registered on July 4, with a capital of £20,000 in £10 shares, to enter into an agreement with B. M. Fletcher to acquire patents relating to a system for employing or utilising sea or other wave power, takes power to carry on the business of an electric light and power company in all its branches. Mr. Fletcher is to be chairman, managing director, and engineer of the company.

Harrogate.—At a special meeting of the Town Council the Electric Lighting Sub Committee reported that they had resolved on the requisition of not less than six owners or occupiers to lay mains for the purposes of general supply of electricity along any street or part of a street in the area of supply, but outside the compulsory area. A resolution was received from the Highways Committee complaining of the way in which the Electric Lighting Committee had laid the cables under the footpaths in the streets.

Devizes.—A special meeting of the Town Council has been held for the purpose of considering an application by Messrs. Brown and May, Limited, for a concession to enable them to supply electric lighting to customers in the town. After a lengthy discussion, a resolution was unanimously agreed to appointing a sub-committee to ascertain whether there was likely to be any demand for electric lighting, and to recommend to the Council the advisability of considering the supply of the same, whether by contract or otherwise.

Wells (Somerset).—The town clerk has reported that the Royal assent had been given to the Act confirming the provisional order for lighting the city by electricity, and that in accordance with the resolution of the Council he was now about to instruct Dr. Hopkinson and the city surveyor to proceed with the preparation of plans and estimates, in order that as soon as the Act was published he might be able to apply to the Local Government Board and the Board of Trade for the necessary sanctions for loans and approval of system.

Blackpool.—The electric light has been installed at the Empire the current being generated on the premises. The plant has been fixed in the basement, and consists of a 25-h p. gas-engine and a non-magnetic dynamo, capable of supplying 750 16-c.p. lights, with a consumption of 900ft. of gas per hour. The National Gas Engine Company, Ashton under-Lyme, are responsible for the machinery, which has been running for several days to mutual satisfaction. There was a temporary failure of the town electric light in Bank Hey-street last Saturday.

Bromley.—Mr. Craig, highway surveyor for the district, reported at the meeting of the Rural District Council in regard to the application of the National Telephone Company to erect tele-

Digitized by Google

phone poles along the side of the highway from Keston Park to Holwood House, that at places the road was already too narrow for the ever-increasing traffic, and that the poles should be kept at least 4ft. outside the water-tables, which could not be done unless the poles were set in the bank. The matter was adjourned for consideration by the highway authority the following week.

Kirkby Lonsdale.—The electric lighting of Mr. Harris's house at Lunefield has just been completed. It is a seven-kilowatt plant, but is noticeable as the motive power is derived from the Mill Brow Beck. The dynamo is fitted with special carbon brushes and self-oiling bearings, in order to reduce attention to a minimum whilst running. The speed is 1,280 revolutions per minute. The current is carried a about a quarter of a mile to the house. The power-house was formerly a flour mill. A considerable fall has been obtainable, and a Gilkes' turbine has been put in to drive the dynamo.

Edison and Swan United.—The directors of the Edison and Swan United Electric Light Company, Limited, have determined to recommend the payment of a dividend in respect of the six months ended June 30 at the rate of 5 per cent. per annum on the "A" share capital of the Company, as now paid up, carrying forward about £5,000 as against £3,700 in the previous year, which together with the interim dividend at the same rate already paid in February in respect of the first half-year, will be equal to a dividend of 5 per cent. for the entire year. The dividend warrants will be posted on August 12.

Merthy Tydfil.—The Lords' Select Committee of the House of Lords on electric lighting provisional orders have considered the Bill promoted by the Corporation for powers to light their district by means of electricity. Mr. Lewis Coward, Q.C., appeared for the promoters, and Mr. Williams for the Merthy Tydfil Gas Company, who presented a petition to be heard on certain clauses of the Bill. Mr. Coward urged that the gas company had no *locus standi*, as the ground of their opposition was competition. Their Lordships decided that the gas company had no *locus standi*, and passed the preamble of the Bill.

Portsmouth.—The *Cambrian* (Swansea), in discussing the local tramway scheme, says: "There cannot be the slightest doubt about the success of the Portsmouth Corporation's electric light station. In a letter dated July 10, 1896, the chairman of the Electric Lighting Committee, Mr. Ellis, writes: 'You will doubtless be surprised to know that our output is now so great that we shall have to discontinue taking more consumers until we can get another engine, which is to be of 1,000 h.p.'" It is further added that the Portsmouth Corporation are now making enquiries in Swansea as to tramway working

Putz and Co.—The first meeting of creditors of the firm of F. J. Pütz and Co, chemical and general merchants, at 16 and 17, Great St. Helen's, E.C., has been held. One branch of the business was the purchase and sale of incandescent gas lamps and fittings. An action was, however, commenced by the Incandescent Gaslight Company, Limited, for an injunction against the debtor (the firm is now Mrs. Pütz) to restrain her from manufacturing and dealing in the lamps and accessories, which was granted, and the debtor attributed her insolvency to the action and inability to recover debts due. Mr. Ernest Cooper was appointed trustee of the estate.

Taunton.—At the Town Council meeting the Electric Lighting Committee reported that two boys broke a globe and otherwise damaged a lamp, and the committee had accepted £2, the cost of making good the damage. The committee, however, asked the Council to authorise them in the future to take proceedings against offenders. On the report, Alderman Spiller said he had noticed in the Press that at a Local Government Board enquiry held at Ealing, the cost of the installation of the electric light in various towns was produced. He was glad to see that the cost of the installation in Taunton was the lowest among all the towns where installations had been made.

River Plate.—Under the title of the River Plate Electric Light and Traction Company, Limited, a company has been registered by Ashurst, Morris, Crisp, and Co., with a capital of £300 000 in £5 shares, in order to adopt and carry into effect an agreement with the River Plate Electricity Company, Limited; to carry on the business of supplying electric light and motive power in the Argentine Republic, Uruguay, Paraguay, Chili, Bolivia, Brazil, or any other Republic or State in South America, or elsewhere; as contractors for the construction of rail and tram roads with electrical or other mechanical power. The registered office is 78, Coleman street, E.C.

Coolgardie.—The secretary of Westralia, Limited, has intimated to the shareholders that a company was promoted by Westralia Limited, to acquire and work a concession obtained from the municipality of Coolgardie for the lighting by electricity of that town. The directors now state that the lighting of the town was initiated on June 6 by the Mayor of Coolgardie, in the presence of the members of the Town Council. Further plant is under tender from firms in England, and it is confidently expected that when this is erected the lighting company will have entered the dividend earning stage. Westralia, Limited, holds a very large proportion of the capital of the lighting company.

Kidderminster.—The Select Committee of which the Duke of Westminster is chairman has had before it the Bill for a provisional order, promoted by a private company, for power to construct a tramway, to be worked by animal power or electricity, between Kidderminster and Stourport. The Bill had been before the Commons Committee, which, after 14 days' hearing, on the opposition chiefly of the Great Western Railway Company, who own certain branch lines in the district, found the preamble proved. Mr. Lewis Coward, Q.C., appeared for the promoters; and Mr. Pollock, Q.C., for the Great Western Railway Company. Ultimately, after hearing the evidence, the committee found the preamble proved.

Wolverhampton.—At a meeting of the Town Council a discussion took place upon the electric lighting works and their extension. One speaker said that with the exception of Manchester no town had made a profit during its first year's working of the electric light, while many towns had suffered heavily. Bristol during its first year's experience, incurred a loss of £4,090 and £2,509 in its second year; while Burton, Worcester, Dewsbury, and Bradford had also lost substantial sums as the result of the first 12 months' working. The loss in Wolverhampton was only £241 during that term, which was considered satisfactory. Some of the councillors, speaking from their own experience as manufacturers using the electric light, said it was cheaper and better than gas.

London County Council.—The Council's Committee have sanctioned an application made on behalf of the National Telephone Company for permission to lay two cables along the whole of the Garrick-street subway, as shown on a plan submitted with the application. It was further reported that the work at the electric meter testing station in connection with the registration of meters tested, and of the fees due, had fallen considerably into arrear owing to the increase of business at the station. So that there may be no undue delay in obtaining payment of the fees, and in order to overtake the arrears it is proposed that an additional clerk should be employed for three months at a salary not exceeding 30s. a week. The Establishment Committee are to select a man for the purpose.

Bury St. Edmunds.—The Town Council, after having adjourned the question for a month have now adopted the electric lighting scheme. Several of the members of the Town Council are interested in the local gas company, and the town clerk (Mr. C. Salmon) had given his advice that they might nevertheless vote on the point. However on the opening of the discussion, Alderman Lake, who supported the scheme, intimated that if they did so their action would be challenged. Alderman Floyd said the directors of the gas company had decided to abstain. This made the matter a foregone conclusion, and the report of the committee recommending the scheme was carried most of the known opponents of it taking no part in the division. It will be remembered that the proposal is to light the whole of the streets with incandescent lamps, but to supply private lighting in a restricted area only There are to be four arc lamps. Mr. Medhurst is the engineer.

Edinburgh.—At a meeting of the Electric Lighting Committee of the Town Council it was resolved to recommend the Magistrates and Council to accept an estimate for additions and alterations at the central electric lighting station, Dewar-place, amounting to between £4 000 and £5,000. The question of the proposed depreciation or reserve fund in connection with the electric lighting undertaking of Edinburgh has also been under consideration of the Electric Lighting Committee Prof. Kennedy, the Corporation's consulting engineer, attended the conference. With the exception of the treasurer, the meeting, it appears, was practically unanimous in favour of the establishment of a fund of some sort for renewal of perishable parts of the undertaking. The treasurer, on the contrary, is stated to have given expression to the view that there was no reason for establishing a depreciation or reserve fund, and that the whole electric lighting surplus of this and future years should go to the relief of the rates.

Appointments Vacant.—The Cape Town and Suburban Electric Lighting Company, Limited, invite applications from qualified engineers for the office of electrical engineer to manage the electric lighting of the company, and to carry out any new constructive work which may be required. The commencing salary is £300, and first-class passage will be paid to colony. Applications, stating age, qualifications, and experience, with copies only of testimonials, should reach Messrs. Davis and Soper, London agents, 54, St. Mary axe, E.C., from whom all further particulars may be obtained, not later than 31st inst.—The Rochdale Corporation want a working engineer to take charge of precipitation-tanks, sludge pressing machinery, and electric lighting plant at the sewage-disposal works, Rochdale. Wages, £2. 5s. per week. Application to Mr. S S. Platt, borough surveyor, Rochdale.—The Plymouth Corporation want an assistant to the borough electrical engineer. The salary is £150, and particulars are obtainable from the town clerk.

Charing Cross and Strand Corporation.—The directors of the Charing Cross and Strand Electricity Supply Corporation, Limited, have invited subscriptions for an issue of 10,000 4½ per cent. preference shares of £5 each at par. The prospectus states that the net profits for the half year ending June were £10,181, which were derived from the supply of electrical energy within the parish of St. Martin's in-the Fields. In order to meet the outlay for the erection of the station and machinery at 85, Commercial-road, as also for the laying of mains in the Strand district and for other purposes, the directors have taken powers to increase the authorised debenture issue from £100,000 to £150,000, and to issue £100,000 of preference shares. The sum of £50,000 is now required, and a further issue of preference shares will be made as and when the necessity arises. The list closed on Thursday. The directors have declared an interim dividend for the half-year at the rate of 5 per cent. per annum on the ordinary shares carrying forward £6,100, after payment of all interest on debentures.

Liverpool.—At a meeting of the Lighting Committee of the Corporation, Councillor Petrie presiding, Mr. Bellamy, gas inspector and superintendent of street-lighting, presented a report

Digitized by Google

respecting the lighting of the plateau in front of St. George's Hall and a portion of Lime-street in the immediate vicinity. He detailed the existing lighting arrangements, and suggested the substitution of the electric light for the majority of the present gas lamps. The committee adopted the report, and decided to recommend the Council to carry out the scheme. At the half-yearly meeting of the shareholders of the Liverpool Tramways and Omnibus Company, on Saturday, Sir David Radcliffe, the chairman, said the Corporation had approached the directors with a view to ascertaining whether, if some efficient means of mechanical traction were proposed by them, the company would be prepared to consider the working of it. The directors had expressed their readiness to move with the times in the matter of mechanical haulage, and wanted to adopt something which would not only do their work well, but which would also look well and be a credit to the city of Liverpool. A new overhead railway station at the Herculaneum Dock has been opened.

Chiswick.—A Local Government Board enquiry has been held with reference to the erection of a chimney shaft at a cost of £650. Mr. Ramsden explained that two years ago the Chiswick Local Board leased to the Bourne and Grant Electric Lighting Company, Limited, a piece of land on which to erect a lighting station for the supply of the electric light to the whole parish. The lease was for 42 years, with the option to the Council of purchasing the company's rights at the end of 21 years. The company submitted to the District Council plans on which the shaft was shown, and the Council then approached the company with the view of securing that the shaft to be erected should be of sufficient capacity to be utilised for the purposes of a dust destructor. The foundations of the lighting station had been already put in, but the whole of the works had been stopped pending the sanction of the Duke of Devonshire to the erection of a dust destructor. That sanction had now been obtained, and the plans had been modified by the Council to show a shaft enlarged in diameter and increased in height, from 60ft to 150ft. The saving which it was estimated would be effected by the erection of the enlarged shaft was £1,000.

Birmingham.—A meeting of the shareholders of the Birmingham Central Tramways Company, Limited, has been held to consider an agreement between the directors and Messrs. William Mackenzie and James Ross, representing a syndicate for the transfer of the business of the company for a consideration equal to par value of the debentures and preference shares of the company, and a sum of £6 for each £5 ordinary share, with interest at 5 per cent up to the completion of the purchase ; and a further proposition that, for the purpose of this sale, the present company be wound up. The assent of the Board of Trade and the Birmingham City Council as the lessors of the lines to renewed leases have been obtained, and as an inducement to the consent of the Corporation the syndicate have made several important concessions, among them the abolition of steam and the general adoption of electricity as a motive power. The syndicate propose to form a new company, with a nominal capital of a million and a quarter sterling—the capital of the present company was originally £650 000, but the ordinary shares were written down half from 1894, bringing the total to a little under half a million sterling—and to take over all the liabilities and assets of the existing company. The purchase money is £485,000. The purchase was agreed to unanimously

Cardiff.—At a meeting of the Lighting and Electrical Committee, Mr. N. Appelbee, manager of the electric lighting works, presented a report showing that the total number of 8 c.p lamps connected up to June 30 was 12,642, as compared with 4,992 in the corresponding period of 1895, being an increase of 7,650 Total Board of Trade units generated for the month of June 16,558, calculated revenue for the same—public arcs, £78 ; private supply (approximate), £195. 17s. 1d. ; total (approximate), £273. 17s. 1d. ; revenue for the corresponding month of last year, £141. 16s. 6d. ; calculated increase, £152. 0s. 7d. Mr. N. Appelbee further reported upon the breakdown and cessation of the electric lighting on the night of the Royal visit on Saturday, the 27th ult. He said that at the time the two triple-expansion engines were running separately on the load, being one on each of the two mains which supply the town. Each engine was developing about three-quarters of its full power. At about 10 p.m it was found that the big end of the intermediate rod of No. 2 engine had become heated, and as it could not be kept under the engine was shut down, and its load put on No 1 engine, which was thereby somewhat overloaded After a short time this engine also warmed up and had to be shut down to ease the bolts on one rod, thereby causing a total extinction. The cause of the whole affair was due to the heating-up of the first engine—*i.e.*, No. 2—which might possibly have been avoided by more care on the part of the greaser who was tending it.

City of London.—The Streets Committee have been inspecting the experimental electric lighting of the side streets of the City. First of all they dined together and presented a testimonial to Mr. Berridge, the late chairman and then proceeded to Wood-street to make an inspection of the experimental lighting in that thoroughfare and in the adjacent side streets. It proved a very interesting survey, and the result of the committee's deliberations on the question will be submitted in the shape of a report to the Commission of Sewers. The whole length of Wood-street between Cheapside and Cripplegate-buildings is lighted by gas lamps. In Watling-street, Old Change, Friday-street, Bread-street, and Bow-lane the lamps are arc and incandescent electric lights. Eleven arc lamps light Watling-street, Old Change, Friday-street, and Bread-street. They are supplied with energy from the alternating private supply circuits, and each lamp takes about 250 watts, or half as much as the power taken by a lamp in the main streets. In Watling-street, Old-change, and Bread-street the lamps are suspended above the centre of the carriageway from girders or rods fixed to the houses. In Friday-street, for the sake of comparison, the lamps are fixed on brackets Bow-lane is lighted by incandescent lamps fixed on five brackets. They are supplied with energy from the alternating private supply circuits, and take about 200 watts each, except the three lamps fixed on one bracket, which together take about 200 watts. At the Cannon-street end of Bow-lane three lamps have been fixed instead of one, with a view to determine whether improvement in distribution can be thereby obtained.

Leeds.—The British Thomson-Houston Electric Company have given notice to the Corporation that after the 31st of the present month they will cease to run their present service of electric cars on the Roundhay-road. This decision of the company appears to have been somewhat hastened by the letting of the tenders by the Corporation for the proposed new service of electric cars from Roundhay to Kirkstall. Mr. Hannam, the chairman of the Highways Committee, believes that in six months the alterations in the permanent way from Roundhay to Kirkstall, rendered necessary by the adoption of the new system, will be completed, and he sees no reason why, in eight or nine months from now, electric trams should not be able to run from Kirkstall Abbey to Roundhay Park. The construction of the works for the overhead electric traction system has just been commenced. At the new entrance to Roundhay Park in Prince's avenue the central line of a double track of tramway has been laid out, and the chairman of the Highways Committee formally started the work of digging for the foundation of the new track. The total length of the track work for the whole route is seven miles, for, although some 6½ miles of track is already laid, all of this will have to be taken up either for renewal or rearrangement as to gauge, etc. The whole of the contracts for the electrical part of the work are required to be completed within six months, and as in the nature of things the tracks must be the first portion of the work completed, the committee have divided this work into such a number of contracts that most of the paving and flagging contractors of the city have a share of it, and it is contemplated that all of this part of the work will thus be completed within the next four months. With a view to minimising the interference with the street traffic it has been arranged that the work in the crowded part of the city shall be proceeded with night and day.

Brighton.—The report presented by the Electricity Lighting Committee at the meeting of the Corporation stated that for the purpose of equalising the distribution of pressure it would be necessary, before next winter, to run inter connecting mains in certain streets, the total cost of which was estimated by the borough electrical engineer (Mr. Wright) at £860. He estimated that the profit on the supply of electricity to the gas lamps in these new streets would be £23 per annum As this inter-connecting from the side streets would certainly improve the pressure, and at the same time give the inhabitants opportunities for taking a supply of electricity, he trusted the committee would sanction this work being put in hand, for which the money was borrowed at the last enquiry The committee approved of Mr. Wright's proposal, and recommended that the public lamps along the line of such new mains be lighted by electricity instead of gas. The adoption of the proceedings was proposed by Councillor Stafford and carried. In his financial statement the chairman of the Finance Committee of the Shoreham Harbour Trustees (Mr. Sundius Smith) said that the importation of coal by the Brighton Gas Company to June 30 last was 41 560 tons as against 43 074 tons for the year ending June, 1895 The exceptional weather in the two periods was well known, but the effect of electric light was, perhaps, not so well known. From the returns of the Brighton Corporation and the Hove Electric Lighting Company to the Board of Trade, they sold an amount of electric current equal to one hundred million cubic feet of gas during the year 1895. This meant that had this not been so, some 10,000 tons more coal would have been required for gas manufacture, the whole of which would have entered Shoreham Harbour, and would have contributed to their revenue. Probably if the Trustees had enquired, they might have obtained the actual coal consumption at the generating stations, which would have been more to the point.

Oldham.—Lord Derby has given notice that he will in the House of Lords move a number of amendments to the Tramways Provisional Orders (No. 2) Bill, in which the Oldham, Ashton-under-Lyne, and Hyde district order is included. In Clause 6 his Lordship suggests that an alteration should be made to the effect that no junction should be constructed with the tramways of the borough of Oldham. For the protection of the Manchester Carriage and Tramways Company, he proposes to add to Clause 14 words to provide that the promoters shall not commence the construction of any part of the tramway No. 7 where the same shall be within 18in. of or between the rails of the tramways of the Manchester company at the said point of crossing until one month after notice has been given, the notice to be accompanied by particulars of the proposed works. If before the end of the month or of 48 hours (in the case of repairs) the Manchester company give notice that they desire themselves to execute the works of construction, maintenance, or repair, the Manchester company shall be empowered to do so. A new section provides that the promoters shall keep all posts, wires, and apparatus within 20 yards of the tramways of the Manchester company in good condition, and by another section the promoters are to work the traffic on tramway No. 7 (an electric line) where it crosses the tramways of the Manchester company so as not to impede the traffic upon the tramways of the latter company, and no vehicle on tramway No. 7 shall be permitted to approach within 10 yards of the crossing at any time when any vehicle of the Manchester company is

Digitized by Google

approaching the crossing and is within 30 yards thereof. A further section proposes that the promoters shall so construct and maintain the electric mains, wires, etc., as not to interfere or impede the tramways of the Manchester company and so as not to interfere with or affect the adoption by the Manchester company of electricity or other mechanical power as a motive power upon their tramways, and any overhead wires erected or used by the promoters under the powers of this order shall be at least 20ft. above the level of the tramways of the Manchester company at the said point of crossing. The promoters shall also be responsible for all damages by reason of any default or omission of the promoters.

Aberdeen.—Correspondence from the National Telephone Company was submitted at the meeting of the Finance Committee intimating the company's receipt of the committee's proposal to charge for each telephone pole erected in the city. The company stated that they declined to take any notice of the charge until the question of their request for the Council to lay pipes for the conveyance of the wires underground was settled. The committee unanimously decided to refuse the company's application as to the laying of the pipes. The work of fitting up the electric light in the Advocates' Library has now been completed by Messrs. Shirras, Laing, and Co.'s engineers In all 132 lamps have been fitted up. The current is drawn from the Corporation main, and is regulated by an Edison-Swan distribution board. A joint meeting of the Gas Sub-Committee of the Town Council and the Docks and Pilotage Sub-Committee of the Harbour Board has been held for the purpose of considering the question of introducing electric lighting at the quays. Discussion took place as to which part of the scheme would fall to be carried out by the Harbour Commissioners, and what part the Council would do. It was decided that the Commissioners should provide the necessary standards for the lamps, and superintend the lamps after they are erected. The Town Council, on their part, would supply the current and lay the mains It was remitted to Mr. Nicol, harbour engineer, and Mr. Blackman, electrical engineer, to bring up a report as to the type of mains that should be laid, on what part of the quays they should be constructed, and as to whether it would be necessary to put down two sets of mains—one for lighting and another to convey motive power for dock gates bridges, cranes, etc The meeting was unanimously of opinion that if electric lighting was to be adopted the installation should be of the most complete kind. The Corporation, in view of the additional plant they are laying down, will be able to supply any quantity of current; and it is expected that a considerable revenue will be derived from supplying light to vessels discharging cargo by night and for driving cranes on the quays. As to the price to be charged for the current, consideration of that was deferred until the Gas and Electric Lighting Committee have received a report on the subject from the engineer.

Warminster.—At the meeting of the Urban District Council a letter was read from the Board of Trade asking whether the electric light was still in vogue in the town, and if not whether the cable had been removed. The Chairman said that in reference to the matter they were to have a visit from Mr Mark Hill that day and they would let it remain over till then. Subsequently Mr. Hill came, and after some discussion on the subject of sewage asked whether the Council intended to pay him the money they owed him for the electric light? After a lot of persuading he was induced to allow a cable to be attached to his dynamo. Eventually he allowed it to run at the ridiculously low sum of £15 a year for the one lamp, conditionally that if more lamps were put up he should light them, and that he could continue his cable to light any business houses that required it. All this time he was losing £1 a week on the transaction. Subsequently he got a promise that something should be done. A meeting was held and it was decided to erect more lamps. They came to him and asked what he would light them at, and he gave a price. He went, on the strength of that, to considerable additional expense, including the purchase of another dynamo and cable. Before that could be completed the Smallbrook Mill scheme turned up and they threw him over. He wrote several letters, and finally he was told the Council had Smallbrook Mill, and did not want him. He could not keep on losing money, and he wrote to them accordingly. By and bye, he was compelled to switch the light off Then when he applied to put up other lamps he was told he would do so at his own peril. He sent in a reasonable bill for £50, and they offered him £12 10s., which he did not accept. Someone might say he ought to have kept on and finished his contract, but no one would have done that under the circumstances without some chance of getting his money back. Mr. Hill withdrew, and subsequently, after further discussion on sewage, Dr Alcock asked who it was made the promises to Mr. Hill. The Clerk said the only thing was a certain agreement was made with Mr. Hill to light the one lamp, this being terminable by notice, which was duly given, and expired last March. Ultimately, Mr. Chambers proposed that the Council adhere to the offer made to Mr. Hill in January, 1895 (namely, £12. 10s.). Dr. Alcock seconded, and this was carried. Nothing appears to have been settled as to the reply to the Board of Trade's letter.

Yarmouth—The Electric Lighting Committee reported that since the last meeting applications had been received from five customers for 222 lamps, the total number now being 177 customers or 8,365 lamps. The expenditure for June was £123. 8s. 2d., and the income from all sources £111. 18s. 8d, showing the cost of working over income to be £11. 9s. 6d. In addition to this, there is about £100 for interest, repayment of capital, etc., the actual deficit thus being £111. 9s. 6d. The borough surveyor, in his half-yearly report, submitted that the steadily-increasing demand would soon convert the loss into a gain. The difference between income and expenditure for 1895 was £766, £420 of which provided for the sinking fund. This was 75 per cent below the estimated loss. The income for the present year to date was £1 082, and the expenditure £817, leaving £265 for sinking fund, etc., and as this was estimated at £600 there was a net loss on the six months of £335. The interest charges would be increased next half-year, and would probably amount to £800, but it was hoped that this would be met by an increased income. The money earned in the first half of 1895 was £570, and in the latter half £1 370, whilst that for the half year just ended was £539 more than in the corresponding period last year, the working expenses being only £155 in advance, which latter was largely due to the continuous running through the day. The surveyor estimated that the loss for the whole of the present year would not exceed £400, and as 10,000 lights would be installed by that time, it might be anticipated that in 1897 there would be no loss to fall upon the rates. Mr. Preece being present when the report was given, stated that, after fully considering the financial position of the electricity supply works, he considered there was no cause for alarm as to the ultimate success of the undertaking from the fact that during the summer months no profit was being made. He advised that, wherever it could be done, encouragement should be given to customers to extend the hours during which the current was in use, and that special facilities should be given for the use of motors during the hours of daylight. As stated in the borough surveyor's report, the average earning per lamp wired up last year was 7s. 4d. As 9s. was the average earning of its equivalent in gas, this must be expected to be increased, and that the costs of working last year, which was 3·17d. per unit generated, would most certainly be reduced, and he hoped during the present year to see it reduced to 2½d. The public lighting last year had not been remunerative, but he hoped, as costs of working were lowered, to see this pay its way at the prices now charged. He considered that the present method of apportioning the sum to be paid for the public lamps each month according to the number of hours alight was not a proper one, as the cleaning, fixing carbons, interest, and capital charges were the same throughout the year. He produced tables of curves which had been prepared by Mr. Rankin, showing the lamp connections each month, the income derived from public and private lighting, and the expenditure, and from a study of these curves, and from what he knew of the works, he considered that the present charge of 6d. per unit would be remunerative, and that the prospects of the undertaking were most hopeful, and that as soon as possible it would be highly desirable, in the interests of the Corporation, to reduce the charges to persons taking current during the hours when a light load only was being sent out from the works, and he considered that 4d. per unit would be a remunerative charge. He further stated that for tramways and works of a similar character the current from the Corporation works could be profitably employed. The Borough Surveyor said that several of the proprietors of stalls in the market were willing to lay on the light. The cost would be about £15 for cable and £5 per customer for meter pit. The committee instructed him to ascertain the number of customers willing to come on, and the amount they were willing to guarantee as a minimum quantity for a year's supply, and also the proportion they were willing to pay towards the cost of building the meter pits.

London Extensions—The committee of the London County Council have received and sanctioned notices from the Metropolitan Electric Supply Company of intention to lay mains in Exeter-street, Burleigh-street, Tavistock-street, Southampton-street, Maiden-lane, Covent-garden, Bedford-street, New-street, Bedfordbury, Garrick-street Charing Cross-road, Shaftesbury-avenue, Rose-street Hart-street, James-street, Bear-street, Cranbourne street and alley, Leicester-place, Lisle-street, Little Newport-street, Gerrard-street, Macclesfield-street, Nassau-street, Hayes-court, Dean-street, Meard's-court, Frith street, Greek-street, Church-street, Old, New and Little Compton streets, Queen-street, Richmond-buildings, Carlisle-street, Charles-street, Rathbone-place, Hanway-street, Sutton-street, George-yard, Rose-street, Moor-street, Lichfield-street, West-street, Lumber-court, Tower-street Great and Little Earl streets Dudley-street, Great and Little White Lion streets, Stacey-street, Phœnix-street, Lloyd's-court, Denmark and Little Denmark streets, High-street, Arthur-street, Church-lane, George street, Bloomsbury-street, Broad-street, Great and Little St. Andrew streets, Seven-dials, Upper St. Martin's lane, Castle-street, Chapel-place, Mercer-street, Langley street and court, Queen street (St Giles), Short's-gardens, King-street, Endell-street, Brownlow-street, Hanover-street, Wilson street, Charles-street, Broker's-alley, Drury-lane, Museum-street, High Holborn, Coal yard, Smart's-buildings, Charles-street, Newton-street Cross-lane, King-street, Brewer-street, Parker-street, Great Wild-street, Stanhope street, Harford place, Brydges-street, York street, Wellington-street, Bow-street, Warwick-place, Grove End-road, Melina-place, Elm Tree-road, Hall-road, Circus-road, Garden-road, Hamilton terrace and gardens, Alma-street, Hill-road, Abbey road, place, and gardens, Violet-hill, Nugent-terrace, Abercorn place and mews, Marlborough-place, Edgware-road, Elgin road and avenue, Portsdown-road, Carlton road and hill, Lennard-place, Cavendish-road, Cavendish-road West, Wellington road and place, Eaton-terrace, High-street (Marylebone), Charles lane, Henry-street, Upper and Lower William streets, Barrow Hill-road, Chapel-street, Wilton-place, Charles-street, Park-road, Frederick-street, St. John's Wood road, Oak Tree-road, Lodge road and place, North and South Banks, and outer circle of Regent's Park, Marylebone-lane, Great Portland-street, and Euston-road. The work is to be completed in six months, or the sanction to expire. Some of the work is to be carried on continuously. Two notices have been

Digitized by Google

sanctioned given by the Charing Cross and Strand Electricity Supply Corporation of intention to lay mains in the Strand, Surrey-street, Norfolk-street, Howard-street Arundel-street, Water-street, Milford-lane, Essex-street, The Approach, Catherine-street, Holywell-street, Wych-street, Blackmoor-street, Stanhope-street, Newcastle-street, Clare-street, Holles-street, Houghton-street, Clare-market, Portugal-street, Twining-street, Carey-street, Serle-street, Chancery-lane, Cursitor-street, Church-passage, Bream's-buildings, Clement's-inn, Hart-street, James-street Bow-street, Russell-street, York-street, Catherine-street, Tavistock-street, Wellington-street, Burleigh-street, Exeter-street, White Hart-street, across the Strand in two places, Chandos-street, Beaufort-buildings, Savoy-street, Southampton-street, Tavistock-court, and Covent Garden. The St. James and Pall Mall Electric Light Company has given notice of intention to lay mains in Regent-street, Piccadilly, Piccadilly-circus, Shaftesbury-avenue, Coventry-street, St. James's street and square, Pall-mall, Waterloo-place, Carnaby-street, Ganton-street, King street (Regent-street), Chapel-court, New Burlington-street, Savile row, Vigo-street, Ormond-yard, York-street, Jermyn street, Eagle-place, Mason's-yard, Duke-street, Ryder-street, Bury-street, Charles street, John-street, and King-street (St James's); and there was also a notice from the House-to-House Electric Light Company of intention to lay high and low tension mains in Lexham-gardens, and to construct three transformer-boxes. Both these notices were passed. Sanction was also given to a notice from the Vestry of St. Pancras of intention to lay mains in Camden-road and Cantelow's-road. The usual conditions are attached.

PROVISIONAL PATENTS, 1896.

JULY 13.

15447. A brush-holder to be used on dynamos and motors. George Edward Francis, Warren-lane, Chapeltown, Sheffield.

15479. Improvements in submarine cable-laying appliances. Charles Scott Snell, Culver Park, Saltash.

15517. Improvements in electric batteries. Rodolf Sauerwald and Henry Griine, 4, South-street, Finsbury, London.

JULY 14.

15534. Improvements in the construction of armoured insulating conduits. Alfred George Brookes, 55 Chancery-lane, London. (Russell Teel Elwell, United States).

15585. Improvements in and relating to writing telegraphs. Philip Arthur Newton, 6, Bream's-buildings, Chancery-lane, London (The Gray European Telautograph Company, United States.)

15595. An improved electricity meter for registering the amount of current consumed on direct or alternating polyphase, triphase, or quadruplephase circuits. Frederick John Beaumont and Frederick Hallows, 166, Fleet-street, London.

15606. Improvements in printing telegraphy. Joseph Joachim Reifgraber, 53, Chancery-lane, London.

15614. Improvements in electrical relays. Willoughby Statham Smith and William Puddicombe Granville, 24, Southampton-buildings, Chancery-lane, London.

15622. Improvements in alternators. Howard Blain Little, Norfolk House, Norfolk-street, London. (Complete specification.)

JULY 15.

15677. An improved electrical counter. John George Dixon, 70, Palace-chambers, Westminster.

15678. Method and apparatus for utilising the mechanism of existing windmills for generating and storing electricity. Frederick Gray, 106, Priory Park-road, Kilburn, London.

15696. Improvements in the manufacture of tubes by electro-deposition. Edward Casper, 4, South-street, Finsbury, London.

15704. Improvements connected with joint or like boxes and appliances or attachments to be used therewith for electric and like wires. Charles Newton Russell, 166, Fleet-street, London.

JULY 16.

15768. An improved electromagnetic brake for vehicles. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Union Elektricitäts-Gesellschaft, Germany.)

15777. Improvements in electrically-actuated vehicle wheels. Charles Théryc, 45, Southampton-buildings, Chancery-lane London. (Date applied for under Patents, etc, Act, 1883, Sec. 103, January 30, 1896, being date of application in France.)

15782. Improvements in or relating to electric railways. Archibald H. Brintnell and George Samuel Baker, 111, Hatton-garden, London.

JULY 17.

15834. Improvements relating to the electrolysis of soluble salts especially applicable for the production of chlorine. Antoine Joseph Outhenin-Chalandre, 111, Hatton-garden, London.

15856. A new or improved electric clock. Joseph Pallweber and Adolf Kolbe, 6, Lord-street, Liverpool,

15837. Improvements in electric apparatus for st iking a bell, bells, or the like, or producing other effects by means of and at a distance from a clock. Edward Robert Dale, 77, Chancery-lane, London.

JULY 18.

15966. Improvements in or relating to electric arc lamps. Henry Leitner, 31, Southampton-buildings, Chancery-lane, London. (Complete specification.)

SPECIFICATIONS PUBLISHED.

1895.

10308. Locks and electric signalling apparatus for use in connection therewith. Defert.

12157. Electric lighting specially applicable for lighting vehicles. Berners and Griffin

15703. Electric cables. Hardingham. (Felten and Guilleaume.)

15863. Dynamo-electric or electro-dynamic machines. Statter.

15880. Electric accumulators. Jungner.

16700. Apparatus for supplying electrical energy to tramcars from underground conductors. Siemens Bros. and Co., Limited. (Siemens and Halske).

16701. Contact apparatus and appliances in connection therewith for facilitating the passing of tramcars over crossings and switches in electrical tramways with underground conductors. Siemens Bros. and Co., Limited. (Siemens and Halske).

16737. Electrical apparatus for extracting gold and silver from cyanide solutions. Pfleger.

23515. The manufacture of electric cables. Borel.

1896.

8380. Printing telegraph instruments. Merritt and Joy.

10608. Tumler electric switches. The Edison and Swan United Electric Light Company, Limited, and Proctor.

10816. Electric measuring instruments. Devonshire. (Thomson)

10846. Magnetically affecting the counter electromotive force of the voltaic arc of an electric arc lamp. Thomson. (Coffin.)

11232. Electric current conducting apparatus for electric railways. Stendebach and Linker

11471. Arc lamps for alternating-current circuits. Wise. (Fernald and Hubbell)

NOTES.

The New Anglo-German Cable.—The fourth Anglo-German cable was used for the first time on the 16th inst.

Institution of Electrical Engineers.—We have to acknowledge the receipt of the *Journal* of the Institution which completes the papers for last session. We may probably further notice its contents shortly.

Applied Chemistry.—The second International Congress of Applied Chemistry was opened on Monday at the Paris Sorbonne under the presidency of Mr. Berthelot, who in his presidential address referred briefly to the work done on metals with the electric furnace and to the possible influences of acetylene.

Telegrams to Hungary.—It is stated that during the International Telegraph Conference at Budapest an agreement was concluded between the British and Hungarian Telegraph Departments for the establishment of direct telegraphic connection between London and Budapest. Negotiations with that object had previously taken place, but without success.

Electric Light Race-Track.—It is stated that an electric light race-track has been laid out at Rosedale, near Cincinnati. The track is a third of a mile in circumference, and has 1,000 lights, with powerful reflectors. The "grand stand, fences, rails, and outbuildings are all painted a glistening white, so as to intensify the lighting." The effect may possibly be more curious than pleasing.

A Sensitive Relay.—Some time ago a method of making a relay more sensitive by adding a helical spring on each side of the armature was suggested in Australia by a Mr. MacDonald. It has now been claimed as a prior invention of Mr. D. B. Granby, of St. Louis, who, however, appears to have discarded it because he did not want it. Of course, it is an idea that is bound to get tried in more than one place.

Prizes.—Of the awards for 1896 of the French Société d'Encouragement, the Prix Melsens, for the author of an application of physics or chemistry to electricity, ballistics, or hygiene, has been awarded to Dr. Castaing for his work on ventilation. The prize of 2,000fr. for an incandescent lamp of 1 c.p., 100 volts, $\frac{1}{20}$ ampere has not been awarded, but an *encouragement* of 1,000fr. has been given to Messrs. Javaux and Nysten, and a similar sum to Mr. Solignac.

Earth Field.—The mean determination at Greenwich of the horizontal magnetic force with the Elliott instrument for 1895 in metrical units is stated as 1·8387. This is greater than the value given by the Gibson instrument by 0·0064. The difference is larger than in preceding years—viz., 0·0030—the increase of the difference being, no doubt, due to the permanent effect of the iron in the altazimuth building. The magnetic disturbances during the year 1895 were comparatively trifling.

Armature Losses.—According to an article in the *Elektrotechnische Zeitschrift* of July 23, Mr. O T. Blathy, of Budapest, states that he has discovered that there is a greater loss in armatures running on load than theory would indicate. From what we can gather from the limited details, this discovery is remarkable only because incorrect theories have been assumed. Every authority in England acknowledges that the Foucault loss increases with the load, and is not a constant, as assumed by Mr. Blathy.

A Spanish Installation.—The electric lighting of Carballino, in Spain, is the subject of a note in the *Revista Tecnologico-Industrial*. It is calculated on a base of 500 16-c.p. incandescent lamps and four arcs. The generating station is about a mile away from the town, and water power to the extent of about 100 h.p. is obtainable from the River Areuteiro, a 16ft. fall being available. The alternating-current system is adopted, with 2,000 volts on the transmission line and two transformers at the town. The construction has been done by Planas Flaquer and Co. for the concessionary, Don Ramon Laforet.

Paris Exhibition.—A deputation from the London and other Chambers of Commerce has waited upon the Under Secretary of State for Foreign Affairs, Sir Henry Bergne, K.C.B. (head of the Commercial Department of the Foreign Office), and Sir Courtenay Boyle, K.C.B. (permanent secretary of the Board of Trade), at the Foreign Office, on the subject of the arrangements for the forthcoming Paris International Exhibition. The deputation was introduced by Sir Albert Rollit, M.P. (president of the London Chamber of Commerce), and included Major S. Flood Page, Mr. Alex. Siemens, Sir Henry Doulton, and Sir Frederick Abel, K.C.B.

Lightning.—Some cricketers, or, perhaps, merely onlookers at a cricket match, had a narrow escape at Kirton Lindsey, in Lincolnshire, last week. If one of our provincial contemporaries is to be relied on, in Lincolnshire a match is not necessarily stopped even by what is described as a "terrific" thunderstorm. What it says is: "During the progress of a local cricket match a blinding flash of lightning knocked down three men named Holmes, Skinner, and Haydock. The former had his clothes ignited and lay unconscious. Skinner was seriously burnt, and Haydock sustained a severe shock. Others in the immediate vicinity felt the effects of the flash."

The Leeds Tramways.—The great sub-division of the contracts for this important work seems to have caused a good deal of misunderstanding. The divisional contracts for the overhead construction also included the bonding of the rail. This was first awarded to Messrs. Crompton and Co., but that company found that the latter part of the work had not been allowed for in their price, and hence withdrew. The next lowest price was that of Messrs. Siemens Bros. and Co., and now we hear that they, too, decline to undertake the work. We hope that someone will eventually take up the contract, but we understand that it is not a valuable one to dynamo builders.

Italian Thunderstorms.—In last week's issue of *L'Elettricità* no less than nine cases of damage or death from lightning are recorded as having taken place on the 18th or 19th inst. in North Italy. The list makes no pretence to be an exhaustive one, and it is highly improbable that this represents more than a percentage of the total mischief. At Solero, near Alessandria, one flash killed three people and seriously injured three more. An Italian ship at Fiume was struck at the same date, so that the storm must have been of very considerable extent. The crew received a severe shock and were mostly stunned. Alongside the ship struck was another loaded with powder, but fortunately this vessel escaped.

Wonders of Electricity.—A Dalziel telegram from San Francisco, which has been printed by several papers that ought to have known better, reports that Mr. Frank Close, of Oakland, California, has invented "a contrivance for seeing through a wire by an adaptation of the principle by which the telephone is worked, with an apparently similar transmitter and receiver. Attached to the latter is a piece of tourmaline, through which a person looks and sees what is happening at the other end of the wire." The reason of writing this note is simply in order that if any of our readers should come across a reference to the "telectroscope"—the design of the name is strictly on a par with the invention—they will know what that word means.

Digitized by Google

Lamp Economy.—In a paper read before the Canadian Electrical Association, and reprinted in the *Canadian Engineer*, Mr. P. G. Gossler remarks on the subject of the most economical voltage at which to run incandescent lamps—*i.e.*, whether or not to over-run them and put up with the short life. His standard is apparently a 50-volt lamp, which seems curious to us nowadays in England. This, however, does not affect the argument, which results in the conclusion that it depends, among other things, on the question whether the lamps are run at a time of maximum current output or not. Naturally, it would be so, but then the customer who pays at so much per unit for his current will not trouble to consider that. It is his own pocket that concerns him.

New Technical Journal.—We have received copies of the *American Electrician*, a new electrical monthly which has incorporated *Electrical Industries*, and is to succeed that paper. The care which is devoted in America to the appearance and general turn-out of a technical journal has always been noteworthy, and in this respect the new comer can hold its own with the best. One point is the placing of the contents in readably large type on the front page of the unobtrusively coloured wrapper. This is apparently to be sacred ground, from which the advertiser is rigidly excluded. The contributors include some well-known names, but at present we have not had time for a detailed investigation of the contents of the three numbers of our new contemporary now before us. It should be added that the publishing office is 1,315, Havemayer-building, New York.

The Telephone Girl.—The telephone girl is heard by many and seen by few, and some people when they hear her do not appear to be satisfied. She has, however, been put on the stage, and her counterfeit presentment is to be seen nightly at the Theatre Metropole at Camberwell. To those who do not know or are content to ignore the actual working of a switchboard the position of the operator has obvious dramatic possibilities, and hence we have the English adaptation of "La Demoiselle du Téléphone," which was played some time ago with considerable success in Paris. For the English edition the late Sir Augustus Harris and Messrs. F. C. Burnand and A. Sturgess are responsible. The plot, of course, turns on a telephone girl in the execution of her duties overhearing her lover making an appointment with a music-hall "artiste."

Tramways Institute.—The annual meeting of the Tramways Institute of Great Britain and Ireland takes place to-day (Friday), at the Holborn Restaurant. After the election of officers for the year and the appointment of the quarterly meetings for the session, the following papers will be taken: "Mechanics of Horse Haulage," Mr. T. H. Brigg; "Improvements in Horse Haulage Equipment," Mr. W. H. Sleep; "Mail Horseshoes," Mr. F. C. Miller; "Westmoreland Car Starter and Brake," Mr. W. Westmoreland; "Rawling's Patent Car Starter and Brake," Mr. John Rawlings, C.E.; "Mechanical Traction," Mr. J. Sturgeon; "Patent Reliance Check," Mr. J. H. Betteley; "The Brand Electric Railway System," Mr. Franklyn; "Signal Bells and Self-Acting Rain-Proof Seats," Mr. C. Challinger. The dinner takes place the same evening at the Holborn Restaurant.

The City of London Accident.—At the adjourned inquest on the death of Chisholme at the City of London Electric Lighting Company's station at Crosby-square, nothing more of importance was brought out. Tillbrook, the attendant at the St. James's-square sub-station, was called, and denied that he ever did anything to make any of the mains "alive." He merely visited the sub-stations to take readings of the supply of electricity to customers, as well as to see that the switches were in order, and to feel the secondary connections to see whether they had become warm or not. The jury then wandered off into the question of whether the company paid their workmen an ideal rate of wages, and ultimately returned a verdict of accidental death, adding various recommendations and opinions which, if they had been founded on expert evidence or a knowledge of the subject, might have been of value.

Self.—Several French writers on electrical subjects have recently got into a really very funny way of using the English word "self"—at least, it looks so to an Englishman. For instance, in the course of an elementary explanation of the phenomena of alternating currents by means of the hydraulic analogy, *L'Etincelle Electrique* speaks of "un circuit electrique à self et capacité," and similar expressions are constantly being met with. Of course, it all arises from taking over the English expression "self-induction" and then dropping the latter part of it without considering what the result may be on the meaning of the remainder of the compound. The French have a right to do as they choose with their own language, and the English language will not be hurt by one of its words being used wrongly abroad. But it seems a needless sort of barbarism among writers who are usually far more careful of their style than we care to be on this side of the Channel.

Current for Montreal.—It is stated that the Lachine Rapids of the Canadian St. Lawrence are to be utilised as a source of power. For some time work has been prosecuted on a large wing dam that runs out for more than a thousand feet into the St. Lawrence River. A fall of water is secured by means of a dam sufficient to develop at the low-water season about 15,000 h.p. This water power is to be transformed into electric current. Upon the dam a power-house will be built that will run its entire length and show an unbroken interior of 1,000ft. in length. The basement of this will be occupied by Stilwell and Bierce waterwheels. The main floor will contain the dynamos, of which there will be 12, each of 1,000 h.p., or 12,000 h.p. in all. They will generate current for transmission to Montreal, for use there in lighting the city, operating the street railroads, and for any and all other lighting and power purposes.

Water Power.—People are always talking about utilising water power, but if anyone does it they are more discontented than before. An anonymous "Tourist" has written a long letter to the *Daily Chronicle* objecting to the Duke of Fife lighting his new house electrically, because he (the tourist) fears that it may result in there sometimes being a little less water to come down the Linn of Corrymulzie The pretension of the townsman that anyone in the country must do nothing with his own property that interferes with the tripper's idea of what looks rural or romantic when he happens to take his holiday, is getting just a little extravagant. What would "Tourist" say if the Duke of Fife objected to an alteration of "Tourist's" shop or office on the ground that he came along the street once a year and did not think it would look quite so well as before, and, further, insisted on a right to interfere as to the water supply of the fountain in "Tourist's" villa garden.

Sparks Wanted.—In the old days, when the "music of the future" had not become the music of the present, or, to be more accurate, a rather small part of it, a great deal of fuss used to be made about the scenery and effects in connection with the Wagnerian operas at Bayreuth. It is to be regretted that the traditional—though, even then, not unquestioned perfection—does not seem to have been

Digitized by Google

maintained, and, from our point of view, still more regrettable that the electrical department appears to have been in fault. From this cause, at the last performance of "Siegfried" at Bayreuth, when the magic sword was being forged no sparks were obtainable. The smithy fire also misbehaved. But then in the old days they left the dragon, who is an important performer, without his head, this part of him having got sent to Beirout, in Turkey, instead of Bayreuth, by mistake of the forwarders. So, after all, things might have been worse without violating precedent.

Personal.—Mr. Joseph Laffargue has received from the French Government the honorary distinction of promotion to the rank of officer of public instruction. Mr. Laffargue is known in connection with our esteemed contemporary, *L'Industrie Electrique*.—The Executive Committee of the City and Guilds of London Institute have appointed Mr. W. E. Dalby, since 1891 university demonstrator of mechanism and applied mechanics at Cambridge, to the professorship of mechanics and applied mathematics at the institute's technical college, Finsbury, rendered vacant by the resignation of Prof. Perry. Mr. Dalby served a seven years' apprenticeship in the locomotive works of the Great Eastern Railway, and gained a Whitworth Scholarship in 1883. In 1884 he entered the service of the London and North-Western Railway; graduated B.Sc. (London) in 1890, and in 1894 received the full degree of M.A. *honoris causâ* from the University of Cambridge.

New Arc Lamp. — In Koerting and Mathiesen's alternate-current shunt arc lamp, instead of employing the usual attraction of a magnet in its armature for striking and regulating the arc, the inventors make use of the inductive repulsion of the rings placed in front of the poles of an alternate-current magnet. For this purpose there is employed a horseshoe electromagnet, having a core and coils, the ends of the core rising above the induction rings. A full description would be unintelligible without detailed drawings, but it is claimed for the principle involved that the "magnet with inductive repulsion" has an advantage over magnets with armature attraction, in that the position of the armature is without influence on the coefficient of self-induction of the shunt coils, and hence the lamp potential remains unaffected by the position of the armature. From the mechanical standpoint another advantage is claimed in the absence of a regulating spring, since alternating-current lamps are continually subjected to vibrations which gradually cause the weakening of the spring.

Cable Interruptions.—According to the official list published in the Berne *Journal Télégraphique* of July 25, up to that date the interruptions already noted of the Puerto Plata and Martinique cable and the Amazon Company's line beyond Monte Alegre still continued, as did the communications with Bissao and Bolama, and the Cartagena and Barranquilla lines in Colombia (New Grenada). In South Africa communication between Charter, Salisbury, and Beira, broken on the 9th, was restored the next day, but the Salisbury and Umtali line was interrupted almost immediately (on the 11th), and has not been restored. The Lourenço-Marquez (Delagoa Bay) and Durban cable was not working between the 13th and 25th. The Cadiz and Teneriffe cable was repaired on the 16th, after being interrupted since June 6, and the Jamaica and Colon (Aspinwall) cable, interrupted on June 10, was restored on July 3. The Pará and Maranhao cable was restored on the 16th after a week's interruption. The Shanghai and Nagasaki cable, which failed on the 23rd, was unavailable at the time the list was compiled. Some short interruptions of the Siberian land lines, now repaired, and a general breakdown in Ecuador on the 24th complete the list.

Rontgen Radiations.—It is stated that Messrs. Novak and Sulc have examined nearly 300 substances with a view to ascertain the absorption of the Röntgen rays by chemical compounds. Their method of investigation consisted in attaching rings of glass to a sheet of paper and placing uniform layers of the finely-pulverised materials in the different rings so that the thickness of the layer was 0·4cm. in each case. The paper with the rings was then placed over a photographic plate, which was enveloped in black paper and exposed to the Röntgen rays for a period of 20 to 25 minutes. By comparing the photographic effect of the rays where the substances were interposed, the relative absorptions were determined. A great number of organic compounds containing only carbon, hydrogen, oxygen, and nitrogen appear equally penetrable, and hence it is concluded that the absorption has no relation to molecular weight or the arrangement of the atoms. Organic halogen derivatives have been found to possess much greater absorption, which increased with the number of halogen atoms present. This effect increased with the atomic weights of the halogens, two atoms of bromine having a greater effect than six chlorine atoms, while iodine derivatives were entirely impenetrable under the conditions used in the experiments.

International Catalogue of Scientific Literature.—The international conference under the auspices of the Royal Society has been in every way a success from a scientific point of view, there being a general unanimity on all the questions decided. The new catalogue is to begin with 1900, is to be in English, and is to relate to "pure" science only, applied science being excluded; but the limits are to be decided hereafter. In indexing according to subject-matter regard is to be had not only to the title of a paper or book, but also to the nature of the contents. Moreover, the catalogue is to comprise all published original contributions to the branches of science indexed, whether appearing in periodicals or in the publications of societies or as independent pamphlets, memoirs, or books. The final editing and publication of such a catalogue is to be entrusted to a central international bureau acting under the direction of an international council, which will be responsible for the administration of the enterprise. Any country, however, which shall declare its willingness to undertake the task is to be entrusted with the duty of collecting, provisionally classifying, and transmitting to the central office, in accordance with rules laid down by the international council, all the entries belonging to its scientific literature. The central bureau is to be in London.

The St. Louis Tornado.—The following is from the *Street Railway Review* (Chicago): "A *Review* editor dropped into the luxurious office of Robert Andrews, vice-president of the Pintsch system of gas lighting in New York, as that gentleman was reading a letter from his St. Louis agent, in which was related the details of the great storm. One incident was especially remarkable and particularly interested Mr. Andrews, who was general superintendent of the Wabash railroad in 1872, when a big tornado swept East St. Louis. The railroad lost its round house and other buildings and hundreds of cars, and one 32-ton locomotive was hurled 20ft. from its tracks and thrown into a ditch. But this was not a circumstance to what happened in the recent storm as related in the letter. It seems the Brownell Car Company had just completed 10 very handsome cars for Columbus, O., in which, among other good things, were the Pintsch lights. These cars were loaded on flat cars, and would have left East St. Louis at 6.30 p.m. At 5.30

Digitized by Google

the storm broke in all its fury and six of the ten were badly wrecked. Three escaped unscratched, and one was lifted bodily into the air, trucks and all, turned completely over, and landed on the same flat car within a foot of the space it had been resting on a moment before. This car suffered comparatively little damage although the globes of the gas lamps were shattered. As Mr. Andrews remarked, it was one of those cyclone phenomena which could only happen once in a thousand times."

Excursion to Switzerland.—In connection with the Institution of Electrical Engineers arrangements have been made for a students' excursion to Switzerland. The party of students and their friends will leave London on the evening of Saturday, August 29, and arrive at Bâle on the following evening. It is proposed to spend one day at Bâle, one at Schaffhausen, three at Zurich, one at Lucerne, and three at Geneva. The party will probably leave Switzerland on Wednesday, September 9, but arrangements can be made for any who wish to extend their visit beyond that date, as the railway tickets are available for 25 days. Arrangements can also be made to return by steamboat down the Rhine, which would take about two days, and would cost about £2. 10s. extra. Students who are already in Switzerland can join the party at Bâle. Mr. Webb is endeavouring to obtain permission for the students to inspect a number of the most important electrical works and installations in Switzerland, including the following: the Maschinenfabrik Oerlikon, Messrs. Brown, Boveri, and Co.'s works, the wire-rope and electric power transmissions at Schaffhausen, the Stanserhorn and Mont Salève Electric Mountain Railways, Messrs. Escher, Wyss, and Co.'s turbine works, the two great water-power plants at Geneva, and the Geneva Exhibition. There are still a few vacancies in the party, and applications from those desiring to join should be made without delay to Mr. G. C. Allingham, hon. secretary, Students' Committee, at Eldon House, Lyndhurst-road, Hampstead, N.W. The cost of the excursion is expected to be about £12.

Poor Arcs.—In a paper read before the National Electric Association of New York, and reprinted in the *Electrical Journal*, Mr. H. L. Rogers, of Cleveland, expresses great dissatisfaction with the arc lamp as at present manufactured. Mr. Rogers says: "Let us examine the arc lamp hanging in our streets. We find a device 50in. to 60in. long, made of long tubes or chimneys, a sheet-iron drum, long side rods, and at the bottom a globe-holder. We can see Davy's two pieces of charcoal; one is 12in. long and the other 6in. The rate of consumption has not changed. We realise that the useful length of this lamp is the vertical length of the carbons. Dividing 18in. by 50in., we find that the useful length of this device is only 36 per cent. of its total length. The statement may be made by some enthusiastic observer that there are two pairs of carbons, one pair alongside the other; but he must not forget that with our improved eyesight in 1896 we can look clear through the device and see not only the skeleton, but the marrow in the bones. These carbons are fastened firmly in their respective holders, and the holders are rigid. The burning of the arc causes the carbons to point up quite decidedly. When the current is shut off momentarily, these points fall together, and it very often happens slip by each other and wedge. When the current is again sent through the coil, its lifting power is not sufficient to pull the carbons apart, the lamp is rendered utterly useless, the policeman reports it out, and a deduction is made from the bill of the lighting company to the city. To prevent these deductions, amounting to more than the original bill, a corps of patrolmen are engaged, whose business it is to watch the lamps all night long, to prevent them going out, as a nurse would watch a sick child." We did not think it was quite so bad as this; but doubtless Mr. Rogers knows what they do in America, and what style of papers they like at the National Electric Association. The drift of the sentence referring to the Röntgen rays we simply do not understand.

The Telephone Service.—At a meeting of the council of the Leeds Incorporated Chamber of Commerce on Wednesday the secretary (Mr. Calvert) read some correspondence with the Postmaster-General with respect to a proposed modification of the rule governing the duration of trunk telephone calls in such a way as to enable a second period of three minutes' conversation to be obtained without notice having been given beforehand. The Postmaster-General pointed out that the rule was framed with the object of securing regularity and certainty in the working of the trunk lines and the proper regulation of the traffic, and said he feared that if it were abandoned inconvenience would be caused to persons waiting to use the trunk circuit by the unexpected extension of time which it would be in the power of those in possession of the circuit to claim. In reply to a further letter, the Postmaster-General maintained his former contention, but stated that the efficient working of the trunk telephone lines was a matter which was engaging his earnest attention, Mr. Zossenheim said that, as a rule, two minutes were occupied in getting into communication with the person with whom they desired to speak, and the result was that they had barely commenced their conversation when they were disconnected. Mr. G. R. Portway moved that they should intimate that the reply to their representations was unsatisfactory, and that through the Leeds members they should bring parliamentary pressure to bear in order to bring about a change. Mr. Zossenheim seconded this, and Alderman Lupton went so far as to say that he really felt that the Post Office was trying to make it as difficult as possible to use the telephone. The resolution was carried. Without going so far as Alderman Lupton, these constant complaints made by business men who know what they are talking about, and many of whom are acquainted with the facilities afforded in America and abroad, show that something must be wrong somewhere in the spirit in which the work of supplying telephonic facilities is approached by the only people who are legally allowed to undertake it.

Geneva Exhibition.—The official programme of the excursion designed to cover visits to the principal electric installations in Switzerland covers a period of six days from Monday, August 10. The excursion will start from Geneva on Monday morning at seven o'clock. The works visited will be Lausanne (tramways), Freiburg lighting (150-volt continuous), the Jura Simplon Railway (accumulator train-lighting). The night is to be passed at Neuchâtel. On Tuesday the works visited are the Val de Travers water power, 750 h.p. (65 amperes at 7,200 volts), the Combe-Garrot generating station, supplying Chaux de Fonds and le Locle, another series system of 3,200 h.p. with an 150 ampere current at 14,400 volts; and, lastly, the Neuchâtel town works, with single and tri-phase currents (1,500 h.p. and 4,000 volts), leaving for Berne in the evening. On Wednesday, after visiting the municipal installation at Berne (continuous at 110 volts), the excursionists leave for Langenthal and inspect the Wynau works (2,000 h.p., triphase current), finishing the day at Aarau. On Thursday the Aarau works are seen (two-phase and continuous); and the excursionists then go to Bremgarten and inspect the Zufikon works supplying current to factories at Zurich

Digitized by Google

(1,500 h.p. and three-phase current at 5,000 volts). The day is finished at Lucerne, where the Thorenberg station (alternating current) is visited. On Friday there is an excursion on the Lake of the Four Cantons, followed by a trip up the Stanserhorn by the funicular railway. The Rathausen station is visited (two-phase current), and the night is spent at Zurich. Saturday, the last day of the excursion, is devoted to Zurich and its surroundings, including the Oerlikon and Baden works. The programme is signed by Mr. A. Palaz, the president of the Swiss Association of Electricians. The price of tickets is fixed at from 130fr. to 140fr. (£5. 12s.), according to the number joining. In order to arrange for lodging and means of transport it is essential that application should be made to Messrs. Ruffieux and Ruchonnet at Lausanne, with a deposit of £1 (25fr.) before 10 o'clock on August 8. Excursionists will travel second-class by railway and usually by special train. Accommodation will be provided at good hotels, but single bedrooms are not guaranteed. Ten francs extra (8s.) is required for this. A light breakfast, lunch, and dinner will be taken together. If the whole excursion is not taken, a rebate will be allowed on the scale of 10fr. a day. Arrangements will be made for forwarding a reasonable quantity of luggage. The excursion is, of course, designed in connection with the Electrical Congress at Geneva, which it immediately succeeds.

Tramcar Fenders.—The number of patents that have been taken out in the United States for tramcar fenders is remarked on in the *Street Railway Journal.* These cover devices of all kinds, sizes, and degrees of practicability, and are of such number and variety that among street railway men a new fender has come to be regarded in somewhat the same light as a new car coupler by steam railroad managers. Just how many fenders have been put on the market it is impossible to say, but a good idea of the large number can be obtained from the following incident: Some time ago a street railway manager stated in an interview, which was published in one of the daily papers of his city, that his company was on the look-out for a good fender. The interview was copied by a good many papers throughout the country, and within three months, it is said, 4,000 different fenders were offered him. The manager, in self-defence, was finally obliged to put up a notice on his doors, "No more fenders wanted." While the subject has its humorous side, and while many, if not most, of the devices are utterly absurd in conception and construction, the fact that so much attention has been given to fenders by the general public shows that there is a universal feeling that safety guards of some kind are necessary for electric cars in cities. At first this idea was not generally accepted by street railway managers, and quite a number still believe that fenders are not only not necessary, but often harmful. On the other hand, it is undeniable that they are being adopted in most of the large cities as well as in many of the smaller towns, and our contemporary thinks that all managers operating cars in crowded streets will do well, even if not believing that fenders are of much positive value, to disarm possible popular criticism by the employment of a safety device of the latest and most approved pattern. Another interesting and somewhat remarkable fact in connection with fenders is that, in spite of the enormous number of the fenders patented, but a comparatively small number of types have been adopted to any considerable extent. This might be understood in the case cited of a steam railroad coupler where uniformity of equipment is desirable, but with fenders a different type could be used on each road, or even on each car, without seriously affecting the efficiency of the service. Our contemporary argues that the fact that only about half a dozen types are in use shows that these do all that is requisite. The conclusion does not follow either in strict logic or railway practice, which is sometimes a different thing. Moreover, there is a difference between what is strictly requisite and what is desirable or, at any rate, desired.

A Conduit Rail.—Of the invention of methods of taking current from a conductor in a conduit "closed" or "open" there is no end, nor is there likely to be during the reign of the overhead trolley system, since, however pretty a plan may look on paper, nothing but an actual trial over a considerable length of way in all weathers can prove any device to be really effective, and when the ideal system has been found it will be always open to assert that just as good results can be obtained at less expense. Mr. Charles Sill's plan, which has been patented in America, is to put the conductor inside the rails. The rails form a continuous iron box or square tube, and the collector enters by a slit on the inner vertical side. The following is substantially the description of it as given in the *Scientific American*: "Each rail contains a continuous longitudinal duct, in which is carried the conductor, and on the inner side of the rail is formed a recess, in which is carried a sectional trolley wire which is engaged by a trolley wheel, whose rod is adjustably mounted in a bracket attached to the under side of the car. The upper ends of the trolley rod are drawn together by the tension of a coil spring, and they terminate in wires which lead to the motor, the action of said spring serving to keep the trolley wheels in contact with the trolley wire. The conductor and the trolley wire are normally disconnected, and they are automatically connected as the car passes along the track. This is done by means of a contact making and breaking device, which is adjusted in the inner web of the rail and consists of two rods, one of which carries the conductor and the other the trolley wire, said rods being normally held apart by the tension of a rubber spring. These rods are carefully insulated from the rail, which carries them, so that only upon their being brought into contact with one another by the pressure of the trolley wheel as it passes can any circuit be formed between the conductor and the trolley wire. The transversely extending rod which carries the trolley wire is slidably supported at the upper end of a vertical rod which is carried by the base of the rail, and carefully insulated therefrom. The whole of the insulation is carried out with great care, and the construction is such that all moisture is excluded from the conductor and leakage prevented. The trolley rod is hung pivotally on the upper arm of the above-mentioned bracket, and has a rocking motion transversely to the car, in a slot in the lower arm of said bracket. The trolley rod is joined by a connecting rod to a crank disc, secured on a shaft extending longitudinally to the car, which is connected at each end by bevel gear wheels with the controller shaft on each platform. By turning the controller in one direction, the crank discs operate to press the trolley-rod wheels against the trolley wire, and thus push its carrying rods into electrical contact with the carrying rods of the conductor within the rail duct, thereby forming a temporary circuit on that particular section of the track, during the passage of the car. A coil spring, engaging the trolley rod and the two carrying brackets allows sufficient vertical adjustment to meet the irregularity of the track or the passage of the car wheels over an obstruction." Thus the description in our contemporary. Immediately underneath the rail may be the best place for the conduit or may not, but to mix conduit and rail up together in this way seems likely to be productive of any amount of difficulty. The name of the contrivance is the "duct trolley rail."

THE 1896 MEETING OF THE VERBAND DEUTSCHER ELEKTROTECHNIKER IN BERLIN.

(BY OUR SPECIAL CORRESPONDENT.)

(Continued from page 65.)

The proceedings of Friday, June 19, concluded by an evening in "Cairo." The members of the society, including a goodly proportion of lady members and their friends, assembled in one of the largest restaurants in this exhibition. We then proceeded to walk through the streets of "Cairo," and to inspect the various attractions and scenic effects. The performance in the arena followed, and then the members gathered into the large room of the abovementioned restaurant. Presents were distributed amongst the ladies, and the evening's entertainment was finished by dancing.

Saturday, June 20.—The business was attacked with vigour on this morning, and, thanks to the generalship of the retiring president, Prof. Slaby, was easily concluded by 2 p.m. The programme was as follows:

1. Appointment of officers and council.
2. Selection of the place for the 1897 meeting.
3. Papers to be read and discussed: (*a*) Director Schwieger, on overhead and underground electric railways in large towns; (*b*) Prof. Heim, on a ballistic galvanometer unaffected by external influences; (*c*) Dr. Kaltman, electrician to the city of Berlin, on the effect of the electric problems of the future on municipal undertakings; (*d*) Dr. Görges, of Siemens and Halske, on variable-speed motors having revolving field.

The president elected for the present year was Mr. Stubben, of Cologne. The new council consists of Dr. Buddé, Prof. Slaby, Mr. Naglo, Mr. Jordan (of Bremen), and Mr. Jordan (of Berlin). The members of the larger committee of management were also slightly changed, and I was glad to see that Mr. Feldmann, of Cologne, was one of the new members elected.

The place fixed on for the 1897 meeting was Eisenach, a most picturesque little town in the centre of Germany. I understand that it was chosen so that the members could enjoy the surrounding country rather than for any engineering works to be seen in the district.

After the meeting was over a few gentlemen and I proceeded to the works of the Allgemeine Company to view a few high-tension experiments. The machine used was designed by Mr. Dobrowolsky, and generates current at the enormous pressure of 24,000 volts. The insulation on the coils is largely composed of mica, to enable them to stand this pressure. The experiments were not unlike those shown by Messrs. Siemens Bros. in this country, but the fact that the high pressure was generated direct in the coils, and not obtained by transforming up, formed their great distinction.

Interview with Von Dolivo-Dobrowolsky.

The subject on which I was most anxious to question Mr. Dobrowolsky was naturally that of polyphase work, of which he can justly claim an inventor's interest. The question of who may have been the first inventor by a few weeks, and whether the American were before the Continental experts, is one which in my opinion should be left to the historians to fight over. The real credit lies more in the fact that when the subject of our interview had discovered from his original researches the essential principles of the motor with a revolving magnetic field, he immediately put the same to practical ends. Since then the firm with which his name is so prominently connected has gone forward by leaps and bounds, and the advantages of this invention have been of service to the general public in hundreds of installations where the systems previously known would have been most inconvenient. It is also worthy of note that Mr. Dobrowolsky's patents are granted mostly for practical details and improvements now in general use. In these patents he acknowledges the prior work of Prof. Ferraris covering the first principles of the rotary field work. I found Mr. Dobrowolsky in his own office and very busy, but he kindly spared me a couple of hours of his most valuable time. He told me that the three-phase work could now claim the larger proportion of the total output of machines from the shops of the Allgemeine Elektricitäts - Gesellschaft. The total output of dynamos per annum now reaches the enormous aggregate of between 70,000 h.p. and 80,000 h.p., and their new works, which are referred to elsewhere, will enable the company to double this output easily. Some 20 machines of 1,000 h.p. and over were included in this large total. I next questioned Mr. Dobrowolsky on the vexed question of the drop of potential in three-phase work when used for lighting purposes. This effect has, he told me, been much exaggerated both abroad and in England, as with carefully-designed machines the fall of potential between no load and full load can be kept within 5 per cent. This, of course, is when incandescent lamps form the bulk of the load. He invariably uses the star method of coupling up the fields of the generators, and with the many and important installations carried out to his design has had no complaint of bad regulation. A very large plant is at present being laid down on this system at Oberspree, near Berlin, by the Allgemeine Company. The current will be generated at 6,000 volts between adjacent wires of the three-wire network, and then transmitted to the various suburban districts around the great city. The very best machinery will be used to ensure economy in working.

VON DOLIVO DOBROWOLSKY.

The engines will be triple expansion and condensing, the water supply for condensing purposes being ample. The coal supply can be drawn from any district as the prices may direct, and can be transported to the work either by the river or by one of the two railways which will have sidings to the works. The supply of power for manufacturing purposes is expected to provide the largest amount of load, although a large amount of lighting will be done. Mr. Dobrowolsky informed me that the charge for power would be 10pfg. ($1\frac{1}{4}$d.) and for light 50pfg. (6d.) per unit. With the lighting customers, however, good discounts will be given to regular consumers. The rate of discount will be based on the lamp hours by dividing the unit consumed by the maximum power required for the lamps. It is expected that a large number of electric tramways will be supplied from this station. The voltage of general distribution is fixed at 6,000 so that the fluctuations in pressure may be small. This pressure will be transformed down to 500 volts for motor work and to 120 volts for the supply of light. A low-tension distribution will is provided at these pressures as the demand arises. The magnitude of the district will be gathered from the scale map (Fig. 1). Current will be supplied at the start to the following places: Marienfelde, Britz, Lichterfelde, Spandau, Hohenschonhausen, Friedrichsfelde, Straulau, and Rudow. These places, shown by thick lines under the names, surround Berlin, so that a large mileage of mains will have to be laid. The mains to Spandau will be over 17 miles long, as a direct

Digitized by Google

route cannot be taken. Other suburban towns will be connected as the undertaking progresses till a complete network has been established round the city. The company also hopes to supply a few sub-stations within the area of the town of Berlin, as the increased demand renders the present stations too small for their work. In that case, motor generators will be used to give the requisite continuous-current supply to the existing mains. Certain outlying portions of the town, not at present connected to these supply stations, may also be supplied from the beginning on the three-phase system. The magnitude of the undertaking, together with the economic consideration in the selection of the site and the type of machinery, should ensure a large remunerative load for the station when complete. The day load from the tramlines alone will be a most paying item in the revenue account. The buildings are being erected to contain machinery of 50,000 h.p., but the whole quantity of generating plant will not be installed at first.

I next questioned Mr. Dobrowolsky as to the type of alternate-current motor he would use for the rotary transformers. The advantages of the non-synchronous type, in his opinion, warrant its selection for this purpose. In efficiency, when loaded, there is nothing to choose between the two types—*i.e.*, synchronous and non-synchronous—but in the power factor the synchronous motor has its only advantage. A non-synchronous motor of large output will take some 10 to 15 per cent. more current for a given power than the synchronous one. This disadvantage is more than compensated, in Mr. Dobrowolsky's opinion, by the increased facilities in starting a non-synchronous motor; also, when running, the drive is much more flexible with the motor not running absolutely in step with the generator. There is a slight variation in speed if a sudden load comes on, which prevents undue strain. Again, with a synchronous motor a short-circuit may cause it to fall out of step, after which there is no recovering power, while a non-synchronous motor will always pick up its load again after the temporary short-circuit is removed.

The next point we conversed on was the advantage of the three-phase current for driving the machine tools in a workshop. Mr. Dobrowolsky's firm use this system entirely throughout their works, and carry the sub-division of driving power rather to an extreme. Even the grindstones have individual motors, but a number of small lathes are usually grouped on to one common countershaft driven by one motor. In comparing the three-phase with the direct-current system, Mr. Dobrowolsky assumed that some 200 motors were required in a particular case. That meant 200 commutators and at least 400 brushes. Assuming the motors were well designed and in good order to commence with, it is extremely unlikely that the good condition will continue. If one motor wears its brushes rather quickly, and is not attended to when required, undue wear of the commutator takes place. So it is likely that a few motors will require repairs on their commutators, and that the brushes will be an item to be considered in the annual cost of upkeep. With the three-phase motor all the advantages of the direct-current motor can be obtained, and that without the use of either a commutator or brushes. The construction of the moving parts is also mechanically stronger, and moisture on the squirrel-cage rotor does no harm. It is also comparatively an easy matter to make the field coils waterproof. After seeing the plant at work, I could not but admit that the case for the three-phase motor was proved.

We then tackled the question of starting torque and current, together with the various starting devices used for three-phase work. Mr. Dobrowolsky informed me that a small motor, when connected direct to the full pressure of the mains, would take four or five times the normal current, and give at the same time three or four times the normal torque. Such a large starting torque is seldom required, and hence, except when the motor is used for working lifts or cranes, or some equally heavy purpose, the current at the start can be reduced with advantage. If, however, the generators are large compared to the motors, there is no reason why the motors should not be started by connecting them direct to the mains. This course is adopted in the Allgemeine works for motors up to 5 h.p. For larger sizes the starting current can be kept down by using a transforming device when first switching in. Another method invented by Mr. Dobrowolsky in the early days of three-phase work is that of inserting resistances in the armature circuit. This can, by means of a governor, be automatically short-circuited when a given speed is attained. This method, however, does away with the simplicity of the squirrel-cage construction, as collecting rings are required, and hence is not much used for small motors. A better way is to change the connections of

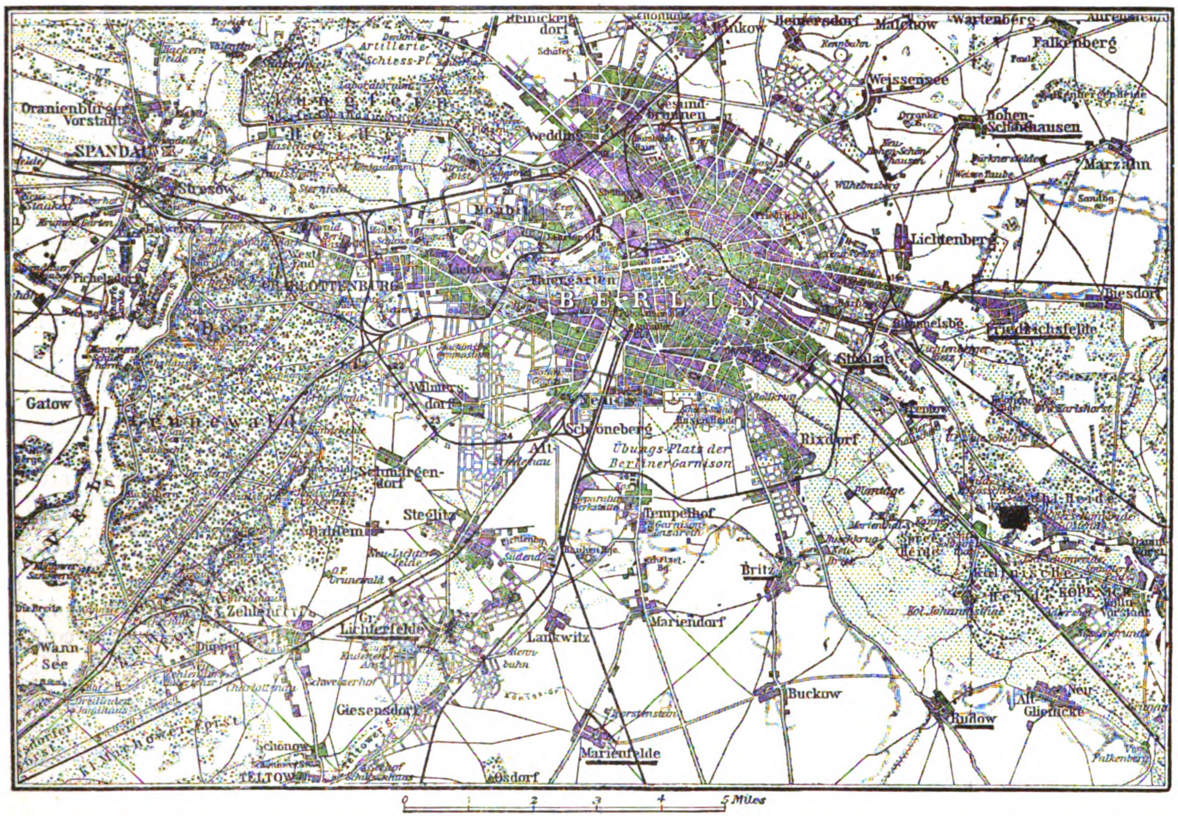

FIG. 1.—Map of the surroundings of Berlin, showing the district to be supplied from the Oberspree Station. ▬ denotes the station which will supply the places of which the names are underlined.

Digitized by Google

the motor by a kind of series-parallel device. Thus, by a simple switching device, the connections of the motor can be changed from the triangle coupling to the star coupling when starting. When this is done, the motor, when connected direct to the supply, will give its normal torque with only 1½ times its normal current. The diagrams of connections (Figs. 2 and 3) illustrate this. Fig. 2 shows diagrammatically the connections used when starting, and which are changed to Fig. 3 as the motor gains speed.

If it is very important to prevent fluctuating, resistance is sometimes put in series with the motor. With very large motors, such as those required in sub-station work for converting alternate currents into continuous, it is preferable to put resistance in the induced circuit. The regulation is then effected on the low-pressure side, and on a large current, which is better than using resistance to be subjected to, say, 6,000 volts pressure. As a guide to

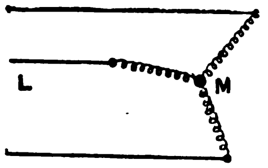

FIG. 2.—Starting Connections.

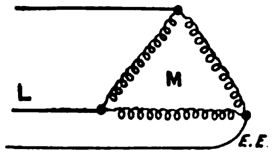

FIG. 3.—Working Connections.

what size motor can be used without starting gear, Mr. Dobrowolsky said that with a 300-h.p. generator a 10-h.p. motor can be switched directly on without disturbance to the surrounding light. The sudden drop then would be under 3 per cent. When using these motors for driving centrifugal apparatus for sugar refining, where a large mass has to be accelerated, care has to be taken that the motor does not take too much current during the time it is gaining speed. In such cases Mr. Dobrowolsky has found it better to design the motor to have more self-induction than usual, rather than to use starting resistances to be varied automatically or by hand. The regulation is then quite independent of the operations, and the motor brings the separator up to speed without straining anything. To show the power of these motors, one 4-h.p. motor in the works of the Allgemeine Company used to drive a wood-planing machine run at the high speed of 4,500 revolutions. When the wood is put to the revolving cutter it takes some 12 h.p., and yet the non-synchronous motor does not break down A high-frequency generator had to be used to drive the

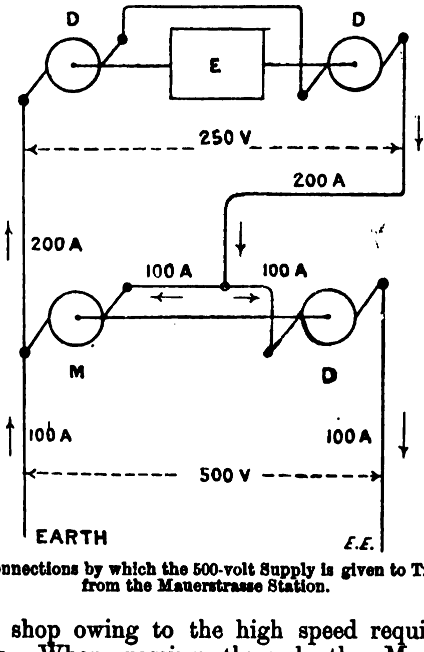

FIG. 4.—Connections by which the 500-volt Supply is given to Tramways from the Mauerstrasse Station.

carpenters' shop owing to the high speed required from the motors. When passing through the Mauerstrasse station of the Berlin electricity works the previous day I had noticed two of the large generators, coupled on either end of an engine shaft, to be running, although all the connecting rods were disconnected. As the Allgemeine Company have had most of this work through their hands, I asked Mr. Dobrowolsky the meaning of the above. He explained that most of the direct-current generators used in these works were wound to give 125 volts for the 110 volts supply on the main. The more recent additions are wound for 250 volts, so as to supply across the outside wires. The two machines I had noticed were these higher-voltage machines, and they were being used to supply 500 volts for traction purposes. The connections used are shown in Fig. 4. The main engine, E, of one coupled set drives the two dynamos, D D, at each end of the shaft. These are 125-volt machines and connected in series; they are used to supply the hitching-up motor generator, M D.

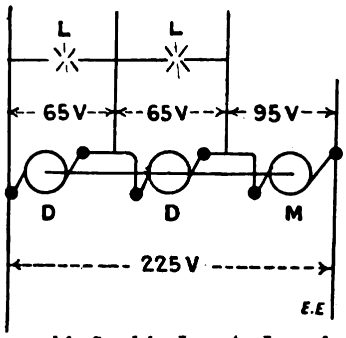

FIG. 5.—Connections used for Supplying Large Arc Lamps from 225-volt Supply.

These latter two machines are wound for 250 volts, and are mechanically connected to the engine crankshaft. The one acts as a motor and enables the other, as a generator, to hitch the voltage up to 500. The approximate distribution of current and voltage is shown. Mr. Dobrowolsky explained to me that by earthing the wire shown the insulation of the low-voltage dynamos was not strained. He also had used a similar arrangement for supplying large arc lamps from the two outside wires of the Berlin system. The connections used are shown in Fig. 5, and with them either lamp can be turned out without affecting the other. As a final subject I asked a few questions as to the conditions in town-lighting which determined the system. Mr. Dobrowolsky agreed that each place required separate consideration, but as a general guide said that for towns included in 1¼-mile circle he should always use continuous current if the station could be placed in the area. If the town was, say, three miles across, and the station outside the town, he should use a three-phase high-tension system. The transformer sub-station in such a case would be equipped with transformers of from 20 to 30 kilowatts. Strassburg has recently been equipped to his designs on the latter system.

EXPERT KNOWLEDGE IN AMERICA.

The New York State recently required an electrical expert to supervise, in the public interest, the equipment and running of electric railways. The various candidates were required to answer the following questions to show their knowledge of the subject:

1. State your age, education, and experience in the electrical business. Give details of positions held and duties performed, with time and place.
2. Give names of your present and former employers in electrical work, with addresses.
3. What type of electric generator is generally used in the electric railway power-house of to-day?
4. When more than one generator is used what practice is generally followed in their operation?
5. Give sketch showing connections of two railway generators when operating on the same circuit.
6. Give list of the protective and controlling devices on a railway generator switchboard, with sketch showing connections of same.
7. (*a*) What method would you employ in insulating generator base from foundation? (*b*) Why?
8. How would you quickly ascertain that the generator and switchboard operating devices were properly installed and insulated from ground while generator is in operation?
9. How would you ascertain if generator and switch-

Digitized by Google

board operating devices are properly insulated from ground when generator is not in operation ?

10. What would be good practice in supporting, locating, and insulating wires from railway generators to outside circuits ?

11. Explain methods employed to build up a generator when it fails to generate when running at normal speed.

12. Give full description of your method of figuring the amount of copper necessary for an even distribution of power on a trolley system with 10 per cent. loss in lines.

13. What drop in potential does good practice allow in the rail and ground return ?

14. Complete the connection between the overhead supply circuit and the return circuit through the car, with list of articles employed therein.

15. What safety devices should a motorcar be equipped with electrically ?

16. What safety devices should a motorcar be equipped with mechanically ?

17. What is your opinion of speeds for electric cars in cities of the second and third classes ?

18. What is your opinion of fenders ?

19. What is a guard wire for electric street railways ?

20. What is your opinion of the utility of guard wires ?

21. (*a*) What is the cause of shocks being received from electric railway tracks ? (*b*) What is the remedy ?

22. Give length and type of car, in your opinion, best adapted for ordinary street railway practice in cities of 100,000 to 500,000 inhabitants.

23. (*a*) What, in your opinion, is the best method of returning the current on a horse-car road which is to be equipped electrically and is laid with flat rails on stringers, if such rails have an iron plate under each joint ? (*b*) If no plates are under joints ?

24. What direct-current potential would you consider dangerous to human life, and what in the case of the alternating current ?

25. Explain the electrolytic disintegration of underground metallic conduits by reason of leakages from railroad circuits. A complaint is made that a water-pipe in a street upon which there is a trolley road is suffering from electrolytic corrosion. How would you determine whether the alleged corrosion was partly or wholly caused by electrolysis, and how would you determine the length of time the pipe would last under such action, and what means would you suggest for its partial or complete prevention ? Should there be any communication between the rails and water or gas pipes, and, if so, at what point ?

26. To what would you connect the ground 'bus of the central station ? Would you advise positive or negative terminals of dynamos to be connected to ground, and give your reasons ?

27. What is meant by over-compounding, and what is its function in practice ?

28. Describe the chief functions of a series-parallel controller for street-car motors.

29. How does the fluctuating character of an electric railroad load affect the choice of engines as regards condensing and non-condensing ?

30. What factors determine the speed of a motor, and what factors determine its power ? Give complete details and formulæ.

ELECTRIC LIGHTING IN BELFAST.*

BY VICTOR A. H. MCCOWEN, ELECTRICAL ENGINEER TO THE BELFAST CORPORATION.

Belfast, like many other large centres, was slow to make advances towards the adoption of a system of electricity supply, the chief reason being that the Corporation preferred that others should experiment, and that they themselves should profit by the experience thus gained. The Belfast Corporation, being the owners of the gasworks, and justly proud of the reputation they had gained of having their thoroughfares well lighted by gas, and the undertaking being also a paying concern, had no intention of allowing private companies to occupy the field. No fewer than seven of the latter in 1882 served notice of their intention to apply for provisional orders for power to supply electricity within the city. All these applications were successfully opposed ; the Corporation remained in possession, and for seven years no further active steps were taken. During these seven years the output of gas had risen from 615 million cubic feet in 1882 to 907 million cubic feet in 1889, and absolute necessity was shown for the extension of the gasworks to cope with the enormously increased consumption. A great difficulty arose as to where a suitable site for that extension could be found. The Gas Committee were thus led to consider the question of the introduction of electric lighting. In September, 1889, they reported that in their opinion the time had arrived when the Council should obtain powers to supply electricity for lighting purposes, etc., within the city, and they also recommended that authority should be given to apply to the Board of Trade for a provisional order for that purpose. Application was duly made and granted, the necessary power being contained in the Belfast Electric Lighting Order, 1890, and by the Belfast Corporation Various Powers Act, 1890. The Gas Committee were authorised to pay £50,000 out of the surplus profits of the gas undertaking towards the establishment of the electric light. Mr. James Stelfox, engineer and manager of the gasworks, reported to his committee regarding the proposed extensions, that "it must remain with the committee to decide to what extent they would anticipate the success of the electric, or any other method of lighting, resulting in a decrease in the demand for gas. . . . . I believe that as yet the use of electricity in any place has never resulted in a lessened demand for gas, and I see no reason to believe that such a result is now probable." The Gas Committee subsequently reported to the Council that they had had under consideration the question of the introduction of lighting by electricity, and that, taking into account the importance of the matter, they recommended the Council to appoint a special committee to procure all the information requisite for the guidance of the Council thereon, and to draw up a report embodying the same. This committee was appointed, and, after visiting the principal electrical installations in and around London and the electrical exhibition at the Crystal Palace, reported in October, 1892, in favour of the establishment of an installation of 10,000 lamps of 8 c.p., with room for extension. It was next decided to obtain the assistance of a consulting engineer, and Prof. Alexander B. W. Kennedy, F.R.S., of London, was appointed. On account of the saving in capital cost, and other circumstances of the case, he recommended the system about to be described.

Area Supplied.—The area at present supplied with electricity in Belfast comprises probably the best part of the city. It includes first-class shops and offices, hotels, clubs, theatres, and churches ; and in Howard-street and College-square private houses. The following tables gives the percentage in lamps connected of different classes of consumers :

	Per cent.
Shops closing late	8·0
Shops closing early	30·0
Shops closing early, but late on Saturday night	25·0
	63·0
Offices	11 0
Hotels and clubs	6·0
Theatres	12·0
Churches	4·8
Private houses	2·0
Motors	1 2
Total	100·0

As shops and offices together form a large percentage of the total consumption, the shape of the load curves depend greatly on their hours of closing. The Saturday curve shows the effect of the late closing of some shops, a much better load being then given with no very objectionable peak. The distance of the farthest lamp from the station is as yet only about 800 yards, as the present area supplied with electricity is only a small part of the city. There is no doubt that when mains are laid in the residential districts the load curve will be greatly improved. A good motor day load is looked forward to in course of time, as there is no doubt respecting the several advantages of electric motors, more especially to small users of power, and where the power is used intermittently. Up to the present the question of street-lighting has not been considered.

Mode of Distribution.—The system of distribution is what is known as the three-wire low-tension. The current is supplied to consumers at 110 or 220 volts pressure. The distributing mains are connected up in a network, and fed at seven points by feeders from the generating station. The feeders deliver the current at the feeding points of the distributing mains at a pressure of 220 volts. The drop in the feeders at full load is 10 per cent. The pressure between the middle wire and the positive or negative is 110 volts. Pilot wires are connected from the feeding points to voltmeters in the generating station, so that the switchboard attendant can always see what the pressure is at these points, and keep it constant by due regulation.

Charges and Pressures.—The charge for current for lighting is 7d. per Board of Trade unit, with discount ranging from 2½ to 17½ per cent. according to consumption; the maximum discount reduces the price to 5·77d. per unit. The charge for current for motors, heating, etc., in daylight hours is 4d. per unit with the above discounts, of which the maximum reduces the price to 3·3d. per unit. Meter rents range upwards from 2s. 6d. per quarter, according to size. Installations containing over 50 lamps of 8 c.p. are wired either with single 220-volt lamps, or with pairs of 110-volt lamps in series, or on the three-wire system. Motors of over 1 h.p. are supplied with current at 220 volts. The meters in use are those of the Ferranti type.

Station.—The generating station is situated between Chapel-lane and Marquis-street, within 250 yards of Castle-place, which is practically the centre of the city; it is therefore a good position from which to distribute the supply. In the selection of the site the question of convenience for delivery of coal, removal of refuse, etc., had not to be considered. The buildings were designed by Mr. C. Stanley Peach, of London. The shape of the site is rather irregular, and the space available has been made use of to the best advantage. The engine-room occupies the central and larger portion of the site, and measures 85ft. long by 33ft. wide at the east end and 44ft. at the west end. A six-ton overhead travelling crane is provided, all the motions of which are actuated from below by means of ropes. The switchboard platform is raised about 4ft. above the floor level, and runs the whole length of the west wall of the engine-room. The battery-room, measuring 28ft. square, is situated between the engine-room and the offices, on the same level. It contains four rows of stands for the cells, and is provided with ample means of ventilation. The offices occupy the west end of the site, with frontage to Marquis-street. The meter-testing room and storeroom are above the offices on the first floor. A fitting-shop and driver's room are placed at the east end of the building, and above them is the cooling tank, measuring 34½ft. by 12½ft. and 4ft. 2in. deep. Owing to the absence of anything like solid foundations to build upon, the whole site was piled with 480 piles of 35ft. length. A 3in. Memel flooring was secured to the pile heads, and on this was placed concrete to a depth varying from 3ft. to 4ft. to form the engine beds and the foundation for the walls of the building.

Engine-Room.—The plant in the engine-room consists of the following engines and dynamos: Four 120-i.h.p. tandem double-acting horizontal gas-engines, running at 160 revolutions per minute, and driving, through eight ⅞in. diameter cotton ropes, four 57·6-kilowatt dynamos of 240 amperes and 240 volts at a speed of 600 revolutions per minute. Two 60-i.h.p. single-cylinder double-acting horizontal gas-engines, running at 160 revolutions per minute and driving, through eight ⅞in. diameter cotton ropes, two 26·4-kilowatt dynamos at 750 revolutions per minute. Two 150-i.h.p. four-cylinder single-acting high-speed vertical gas-engines, running at 380 revolutions per minute, coupled direct to two 72-kilowatt dynamos of 300 amperes and 240 volts.

Switchboard.—The switchboard consists of five slates, each about 7ft. high; the centre one is 36in. wide and the others 32in. All are bolted to an iron framework, fixed on the switchboard platform about 4ft. from the engine-room wall. The centre slate carries the feeder and omnibus-bar voltmeters, the battery instruments and regulating gear, and the middle-wire ammeter and connections. The other four slates carry the feeder and dynamo instruments, switches, etc.; the two on the left hand are for the positive side of the system, and the two on the right hand for the negative side. The machine and feeder bars are fixed vertically on the front of the outer slates. Each is provided with three holes, through which a plug can be inserted to make connection with any one of the three omnibus bars that are fixed horizontally at the back of the board. The feeder bars are connected to the ammeters, to the switches, and to the fuses. From the feeder fuses to the point where they leave the station the feeders are brought in the form of bare solid copper rods supported on insulators, which are fixed behind the matchboarding at the south side of the engine-room. The machine bars are side by side with the feeder bars, and the connections to the machine ammeters and automatic switches are at the back. The leads from the dynamos consist of insulated cables, which are brought along behind the matchboarding at the north side of the building. The automatic switches are arranged to break circuit, should the current from the machine fall below 10 amperes. The shunt change-over switch is shown above the automatic, and connected with it by an interlocking lever. An ampere-hour meter is connected in the circuit of each dynamo, and registers the work done during a run, the readings being taken at start and finish. The voltmeters are Kelvin multicellular electrostatic, and are provided with multiple-contact switches. The feeder voltmeters show the pressure at any feeding point between the middle wire and the positive and negative wires. The bar voltmeters show the pressure between the positive and negative omnibus bars, and also between the middle wire and any of the omnibus bars. The dynamo voltmeters are used for showing the voltage of the machines before putting them on to the circuit. The batteries are connected through their ampere-hour meters, polarised ampere-meters, and emergency switches to the top omnibus bars. The usual practice at full load is to have all the machines and feeders plugged in parallel on this bar; but should it be necessary to run any particular pair of feeders at a different voltage, this can be done by plugging that pair of feeders and a machine on the bottom omnibus bar. As a matter of fact, it has never been required to run a separate machine on a separate pair of feeders, as a very even drop all round is obtained. The link connections in the circuits of the small machines are used for connecting them in the following different ways: (*a*) as balancing machines on either side of the system; (*b*) as a special charging circuit for the batteries; (*c*) in parallel with the large machines across the system. The starting resistances and the shunt resistances are fixed in the cellar beneath the switchboard. The shunt regulating switches are fixed on the handrail of the switchboard.

Battery.—The battery consists of 126 cells of the Electric Power and Storage Company's 34 K or heavy-discharge type—63 cells for the positive side of the system and 63 cells for the negative. The capacity of each cell is 500 ampere-hours, at a discharge rate of 100 amperes. The battery will, however, give a much higher rate of discharge for short periods. The plates are contained in lead boxes which are supported on wooden stands, being insulated from the latter by means of glass oil insulators. There are also eight hospital cells, which can either be used for assisting weak cells, or be put in series with the main battery. The connections from the battery to the regulator and switchboard consist of bare copper rods supported by oil insulators suspended from the roof. The method of regulating the battery is different from that usually practised by cutting in or cutting out end cells. The regulation here is accomplished by putting the cells at the middle-wire end of the positive battery in parallel with those at the middle-wire end of the negative battery; the other ends of the batteries being connected through ammeters and emergency switches to their respective omnibus bars. The regulator is placed in the battery-room, and is worked from a handwheel on the switchboard by means of a rack and pinion. A reversible ampere-hour meter, which registers both charge and discharge, is connected in each battery circuit.

Dynamos.—The dynamos are by Messrs. Siemens Bros., double-pole with drum armature and shunt-wound. The rope-driven machines are provided with heavy flywheels, and the larger ones have three bearings. The two small 26·4-kilowatt machines have double-wound armatures, each winding connected to a separate commutator. By means of a plug-board the armatures can be put in series or parallel, so that the machines can be run at 110 to 120 volts for balancing, or at 220 to 240 volts across the system. The voltage can also be increased to 270 if required. The rope-driven machines are placed close up to the back end of the back cylinder, to save floor space; and backward driving has been adopted, in order to get the slack of the ropes at top.

Gas-Engines.—The six horizontal gas-engines were manufactured by Messrs. Dick, Kerr, and Co., Kilmarnock, under Hartley and Kerr's system. The four larger are double-cylinder double-acting with the cylinders working tandem and the two pistons on the same rod, which is connected through cross-head and connecting-rod to the crank. The bore of the back cylinder is 13⅝in., and of the front 13½in.; the stroke is 20in. The flywheel and driving wheel, one fixed on each end of the crankshaft, are each 8ft. 5in. diameter, and weigh 37cwt. and 29cwt. respectively; the driving wheel is grooved for eight ⅞in. ropes. These engines run at a speed of 160 revolutions per minute and indicate 120 h.p.; the number of explosions per minute is 320, or two per revolution. The two smaller engines are single-cylinder double-acting; the cylinder is 13½in. diameter and 20in. stroke. They run at 160 revolutions per minute, and indicate 60 h.p. The number of explosions per minute is 160, or one per revolution. The flywheel and driving wheel are each 7ft. diameter, and each weighs 57cwt. The cyclical variation in the speed of the tandem engines is very small, owing to the number of explosions, their low initial pressure, and their even distribution, the number of explosions being as four to one in comparison with a single-cylinder single-acting engine. The impulses occur in the following order:

First, Front cylinder,	front end,	angle of	crank	0deg.
Second, ,,	,, back	,,	,,	180deg.
Third, Back	,, front	,,	,,	360deg.
Fourth, ,,	,, back	,,	,,	540deg.

There are thus four complete Otto cycles in two revolutions; and this working is continued right through the whole range of the engine load.

Governing.—The method of governing is different from that usually adopted of missing an explosion. With these engines the impulses are continuous, and are graduated according to the load. Sets of indicator diagrams taken from No. 6 tandem engine at several different loads, from 20 per cent. overload down to only dynamo excited, all ends working right through,

Digitized by Google

showed that no explosions were being missed. In the single-cylinder engines the same even distribution of work done is not obtained, and heavier flywheels have therefore been provided. With the tandem engines it is at once seen that very steady working may be attained without running at a high speed. These engines were originally intended to work down to one-third of full load without missing an explosion; and it was thought that at lighter loads an explosion might be missed and still sufficient steadiness be maintained. It was found, however, that the missing of an explosion at light loads affected the steadiness too much; and the adjustment of the engines was then taken in hand under the immediate personal supervision of Mr. Hartley, with the result of obtaining finely-graduated impulses, such as the writer believes have previously been unknown in gas-engines. The engines are now capable of working from 20 per cent. overload down to no load without missing an explosion. In diagrams taken when the engine was running light and without cutting out it is found that the initial pressure is 60lb. per square inch, the pressure when the piston is at half stroke is 20lb., and the terminal pressure is 3lb. The word explosion seems here somewhat misapplied when one considers the extremely low steady pressure all through the stroke.

Graduation of Explosions.—The difficulty to be overcome was the prompt ignition of the charge without initial shock, and under the difficult conditions of a rich charge varying down to an extremely poor one, and also to reduce the terminal pressure by more complete combustion in the cylinder. Diagrams show the graduated nature of the explosions under varying loads after the final adjustment of the engines. It was noted that the charge ignites promptly and without shock, and that the low terminal pressure shows that the charge is also utilised to the best advantage. The quantity of air supplied to the cylinder is practically constant, the quantity of gas only is varied; and hence the difficulty of ignition. It is well known that a poor mixture of gas and air ignites slowly. The method adopted appears to indicate that stratification actually takes place in the gas-engine cylinder, and that for certain purposes it may be rendered of great use. The regularity of the ignition was attained by admitting gas to the cylinder later and later in the charging stroke; and even at full power a considerable quantity of air is drawn into the cylinder before gas is admitted. At light loads this results in the cylinder being almost full of air immediately following the piston, with only a small portion of rich and explosive mixture near the ignition chest. The ignition is controlled by a timing valve, which opens always at the same point of the stroke. The gas charge is varied by a novel device, which is controlled by the governor. The gas-valve is worked by an expanding cam, which may be described as an ordinary gas cam divided into three leaves in planes at right angles to the axis of the cam shaft. These three leaves are capable of being spread or closed by a sliding key, which slides in a keyway cut in the cam shaft, and is controlled by the governor. A helix upon the key engages the leading leaf of the cam, and when the key is moved longitudinally along the shaft in either direction by the governor, the cam is spread or closed as the case may be. The third leaf is fixed on the shaft, the middle leaf being loose on the shaft and having a slot in which works a pin fixed on the leading leaf. The key and cam are held in position by a detent, during the opening of the gas-valve, but immediately it is fully opened the detent is released, leaving the cam again under the control of the governor. A Buss governor is employed, and the gas-valves are gridiron slide-valves; all other valves are of the mushroom type.

Ignition.—The method of ignition is by hot tubes which are of ordinary wrought iron, nickel steel, and porcelain. The economical life of the wrought-iron tubes is found to be rather short; after about 15 hours the tube gets partially choked up, and gives late firing.

Lubrication and Packing.—The cylinders are provided with valve lubricators opening inwards; the oil is drawn in during the charging stroke. Asbestos packing is used for the piston-rod glands, and no trouble has occurred with hot rods, notwithstanding the high temperatures to which they are exposed; they are as bright and clean as those of a well-kept steam-engine. The lubricant is ordinary gas-engine oil.

Cooling Water.—The cooling water from the overhead tank is circulated by means of small centrifugal pumps driven by belt from the crankshaft of each engine. The evaporation is made up through a ball-cock valve connected with the tank, and supplied by the town water supply. The town water can also be mixed in any required proportion with the tank water. Separate connections are made to the cylinder covers and jackets; and regulating cocks are supplied for the necessary adjustments. When returned to the tank the water is discharged into a long timber shoot provided with a number of holes, by which it is broken up into a shower, thus presenting a larger surface to the atmosphere, whereby the cooling is accelerated. This plan has been found of distinct advantage; and on few occasions has water been required from the town supply, even when running four or five engines together. The capacity of the tank is 10,700 gallons at 4ft. depth.

Gas Supply.—The gas is supplied through an 8in. branch from the Corporation gas-mains, brought into the station at the Chapel-lane end and connected to three 500-light dry meters; the three are connected in parallel, and each is provided with a by-pass. The gas is conveyed from the meters through an 8in. main, which runs the whole length of the engine-room, supported by brackets on the columns. Each engine gets its supply from the main through a 3in. branch pipe, provided with a valve and gas-bag. The ignition gas is supplied through a separate pipe and meters. The horizontal engines each deliver their exhaust gases through 6in. branch pipes into a common 18in. exhaust main. A silencer is connected between the main and the uptake.

High-Speed Engines.—The high-speed vertical engines, manufactured by the Acme Gas-Engine Company, Glasgow, have four single-acting cylinders arranged in two lines of two in tandem, working on to opposite cranks. The pistons in the bottom cylinders form guides in the usual manner. The piston-rod, connecting the top and bottom pistons, passes through a water-jacketed cylinder, the packing being ordinary Ramsbottom rings on the rod. The gas-valves and mixture-valves are of the mushroom type, actuated by means of cams. The piston-valves, which control the exhaust and time the ignition, are worked from a small crankshaft fixed on the same level, and are parallel to the main crankshaft, being geared from it in the ratio 1 to 2 through steel spur and pinion. The camshaft is also worked from this, through an upright shaft gearing with both. These engines being of the closed-in type, the base forms an oil-chamber in which the crankshaft works. The bottom pistons and the bottom piston-valves are lubricated by the splash from the cranks. Lubricators are provided for the top cylinders only. The engine base is extended to take the dynamo, and the crankshaft is coupled direct to the armature shaft. A flywheel of 3ft. diameter is fixed on each end of the crankshaft, the one at the dynamo end weighing 28½cwt. and the other 24½cwt. Each cylinder is fitted with a stop-valve, so that the engine can be run on one or more cylinders as desired. Each cylinder is provided with an ordinary pendulum type of governor, and the usual method of governing by missing an explosion is employed. Ignition is obtained by means of the hot tube. When the engine is running at full load, at its normal speed of 380 revolutions per minute and no explosions missed, 190 impulses per minute are obtained in each cylinder, or a total of 760 per minute in the engine. This, aided by the heavy flywheels, gives a very steady running. The engines are provided with a separate silencer and exhaust-pipe for each line of cylinders. The cooling arrangements are practically the same as with the horizontal engine. Tank water is circulated by means of a centrifugal pump, and there is also a direct connection from the town water-mains. Cooling pipes are also fitted to the crank-chamber. This kind of engine is specially suited for steady driving, high speed being attained without knocking, all parts being in constant thrust. This is obtained by having a high compression (about 90lb. per square inch) in one or other of the cylinders at every up stroke. When the bottom right cylinder is exhausting, the top right is compressing, and *vice versâ*. The same operation occurs in the left line of cylinders, and by cushioning at the top of the piston-valve cylinder, the piston valves are also kept in constant thrust. Where economy of floor space is a consideration, this kind of engine is very suitable. An engine of 150 i.h.p. requires a floor area of 6½ft. by 5ft., or 32½ square feet over flywheels, and the combined plant, engine and dynamo of 72 kilowatts, necessitate only an area of 62½ square feet.

Starting Arrangements.—The engines can be started either electrically or by compressed air. In the electrical starting the dynamo is run as a motor off the omnibus bars, pulling the engine round until it begins to explode. First the machine is plugged on to the omnibus bar, the machine automatic switch being left open. A starting resistance is then plugged into the machine circuit, the resistance switch being on the off contact. The field of the machine is next excited from the omnibus bar, by closing the shunt switch on the top or bar contact. An initial start is given to the engine by the driver, and the current is switched on gradually through the starting resistance. As soon as the dynamo is up to speed the starting current is cut off. The voltage is then regulated by the shunt resistance, and the dynamo switched on to the circuit by closing the automatic switch. The closing of the automatic switch actuates the shunt switch, changing it over from the top to the bottom contact, and the dynamo then runs as a shunt machine. The electrical starting is worked from the switchboard by the engineer in charge. In starting by compressed air the engine has first to be turned by hand by the driver into the correct starting position. The stop-valve admitting the compressed air is then opened, and is again closed as soon as a few explosions have taken place. The dynamo is then run up to speed and its voltage regulated, and it is put on to the circuit in the ordinary way.

Compressed-Air Starting Apparatus.—The air-compressor has two water-jacketed single-acting cylinders of 4½in. diameter and 8in. stroke. The pistons are driven by opposite cranks.

Note.—In Tests I. to V. both ends of the cylinders were working, no explosions being missed. In Tests VI. and VII. one end only of the cylinder was working.

The admission and delivery of air are regulated by slide-valves moved mechanically. The crankshaft carries on one end a flywheel and on the other a mortice-wheel, which gears with a steel pinion on the motor shaft. The power is supplied by a 6-h.p. electric motor, running at 800 revolutions per minute, and taking its current from the mains at 220 volts pressure. The air-receiver is 12ft. long by 4ft. diameter, made for a working pressure of 100lb. per square inch, and tested up to 200lb.; it is provided with safety-valve, pressure gauge, etc. A 4in. air-main from the receiver runs the whole length of the engine-room, with a 2in. branch pipe to each engine. In the tandem engines the connection is made to the back end of the back cylinder. The compressed air is admitted during the impulse stroke of that end by a valve actuated by a cam, thus giving an impulse every second revolution. The gas is cut off from the back cylinder while starting. As soon as an explosion occurs in the front cylinder the compressed air is shut off, the starting cam put out of action, and the gas turned on, letting the back cylinder take up its part of the work. In the single-cylinder double-acting engines the arrangement is the same, with only the difference in working that the gas is admitted to the front end of the cylinder while starting, but not to the back end. In the high-speed four-cylinder engines the compressed-air connection is made to the bottom right-hand cylinder, which for starting purposes is specially provided, firstly, with a valve to close the mixture-admission port, secondly, with an exhaust passage and a valve to close it, and thirdly, with an inlet for the compressed air. The valve of this inlet is worked by a double-throw cam, thus giving an impulse for every revolution in this cylinder. The speed increases quickly; and as soon as the explosions take place in the other cylinders, the compressed air is shut off, the starting cam thrown out of action, and the gas turned on to this cylinder.

Mains, Feeders, and Distributors.—These are mostly bare copper strip in concrete culverts. The strip is simply supported on earthenware insulators placed 6ft. apart, which are held in place by a pitch setting. The strip is laid in before the cover flags are put down; and extra copper can be drawn in at any time without raising the flags. Everywhere the culvert is placed beneath the footway. The lengths average 25 yards, and are built with a fall towards the junction-boxes, in order to all ow any water that may get in to drain off. The average depth of the copper below the surface is 20in. The space required for a three-way culvert for a distributing main is 27in. wide, with a minimum depth of 18in. below the surface. For a five-way culvert, which takes the distributing mains and a pair of feeders, the space required is 34in. wide with a depth of 18in.

Culverts.—These are built of cement concrete in the pro-

Digitized by Google

portion of 5 of gravel and broken stones to 1 of Portland cement. The side walls are 6in. thick and the bottom 4in., all faced inside with cement. The covering slabs are 2in. Kilrush and Caithness flags. The culvert when dry is itself a fair insulator, which is a great advantage where there is a possibility of sometimes getting a sag of the strip between the insulators, as may occur through the carelessness of workmen. At street crossings and under narrow footways where there is no room for a culvert, insulated cables in cast-iron pipes are used. Connections between the lengths of strip, or between cable and strip, are made in the street boxes by means of gunmetal grip boxes, which clamp the ends together. The copper strip is 1in. wide and 0·2in. thick, giving 0·2 square inch section. This is the section used in all the distributing mains, both for middle and outer wires. When the lamp density—that is, the number of lamps per yard—increases, the section of the outer wires can be increased by putting in another strip on the top of the present. The section of the feeders varies from 0·4 to 0·8 square inch, according to the length ; the longest feeder at present is 520 yards.

The distributing mains are all in parallel, and are connected at as many points as possible in order to equalise the pressure. They are brought back to the station to supply current for the lighting, etc. The middle wire is brought back from four different points of the network. The pilot wires are in the form of three separately insulated conductors, twisted together and cased in lead ; some have paper insulation and others impregnated jute. The joints are protected either by a lead sleeve soldered to the lead covering and filled with insulating oil, or by being placed in a special joint-box which is filled with insulating material run in hot. The pilot wires are drawn into cast-iron pipes laid along one side of the culvert. On account of the wet nature of the ground and the comparatively low level of the city, special precautions had to be taken against water getting into the culverts or accumulating in them, and the aim has been to make the whole watertight. The street boxes are built of brick, faced inside with cement, and the bottoms are concreted. They are provided with a cast-iron frame and cover, the latter being filled with concrete. A watertight joint is made between cover and frame by the use of House's slow-setting cement. Junction-boxes placed in the roadway are provided with specially heavy frames and covers, the latter being filled in with wood blocks. The covers are provided with inspection plugs, which allow of a rapid examination of the system being made without lifting the covers. Any accumulation of water can be removed through the inspection plughole by means of a small hand-pump. A record is kept of the condition of the boxes, and of the dates of their having been pumped out. The covers are also lifted periodically for the ventilation of the culverts. No trouble has been experienced from gas accumulating in the culverts. At the laying of the mains all defective gas services were renewed ; and those that ran close to the culvert were coated with a mixture of pitch and tar. The service mains are rubber-covered cables drawn into wrought-iron pipes, which are laid from the nearest street box. They are connected to the Corporation main fuses immediately inside the building. The connections to the distributing mains are clamped in the case of bare copper strip ; and insulated T-joints are employed for connecting to cable. Throughout the system the positive and negative mains have certain relative positions under the footway—namely, the negative main or feeder is everywhere next the kerb, and the positive next the houses.

General Remarks.—From the experience here gained the author is of opinion that a gas-engine station necessitates more attention than a steam-driven station, and more drivers of a better class are required for a given power than in the latter station. A couple of men are always required for the electrical starting of an engine. Without their help the strain on the armature would be too great if the current were switched on when the machine was standing. The following statement shows the cost of current sold from January 23 to December 31, 1895 :

Number of units sold	82,771
Number of lamps connected (equivalent in 8 c.p.)	10,500
Revenue from sale of current	£2,186
Average price obtained per unit	6·34d.

	Cost of production. £	s.	d.		Per unit sold. d.
Fuel (gas)	501	3	0	...	1·450
Oil, waste, water, and stores, including ignition tubes	80	4	3	...	0·233
Salaries and wages at generating station	444	17	4	...	1·290
Repairs and maintenance of buildings, engines, dynamos, and accumulators	93	16	8	..	0 272
Repairs and maintenance of mains	76	4	6	...	0·221
Rents, rates, and taxes	236	0	0	...	0·684
Management expenses, etc.	413	9	11	..	1·200
Insurance	23	2	0	...	0 07
Total	£1,868	17	8	...	5·42

A machine can be started up and got on circuit in about two minutes, the stand-by units being kept plugged-up on the switchboard and the ignition tubes kept hot. For the sake of efficiency the machines are run as near to full load as possible, but as far as governing is concerned, they can be run at any part of their load. The cost of fuel (gas) per Board of Trade unit sold for the year ending December 31, 1895, worked out at 1·45d. This, with gas at 2s. 3d. per 1,000 cubic feet, is equivalent to 53·6 cubic feet per unit sold, or 59ft. per unit generated. The total efficiency of units sold to generated is 91 per cent. This is equal to an average consumption during the year of 44 cubic feet of gas per electrical horse-power hour. A curve for the cost of gas per unit of electricity generated and sold throughout the year shows that it varies very little, whatever the output may be. The cost of engine-room stores, including oil, waste, water, and ignition tubes, amounts to 0·23d. per unit sold, which compares favourably with steam-driven stations. Ignition tubes form a heavy item of the cost. Good results are now being obtained with porcelain tubes, which require only a short time to heat up. The cost of cooling water works out at a low figure, and this is due to the use of a tank of large capacity, which has special cooling arrangements.

The cables and copper strip were laid and jointed by the Corporation workmen. Messrs. M'Laughlin and Harvey, of Belfast, contracted for the buildings, and Messrs. Scott and Sillar, of Aberdeen, and Messrs. William Coates and Son, Belfast, for the roadwork. The cast-iron work was manufactured by Messrs. Maclaren and Messrs. Shaw and Co., of Glasgow, and the cables were supplied by Henley's Telegraph Works Company, Silvertown, and by the Callender Bitumen Telegraph and Waterproof Company, London. The copper strip was supplied by Messrs. Curtis, of Dublin, and by the British Insulated Wire Company. Messrs. Dick, Kerr, and Co., of Kilmarnock, and the Acme Gas-Engine Company, of Glasgow, supplied the engines and dynamos. The compressed-air plant was made by Messrs. Kerr, Stuart, and Co., of Stoke-upon-Trent. The Electrical Power and Storage Company furnished the battery, and Messrs. Holmes and Co., of Newcastle, the switchboard. The station started to supply current on January 23, 1895, with 2,300 8-c.p. lamps ; there are now 13,500 lamps of 8 c.p. connected with the mains. The following statement shows the quantity of units of electricity generated, sold, etc., from January 23, 1895, to December 31, 1895 :

	Units.	Units.
Quantity sold : public lamps—		
Private consumers by meter, at 4d. per unit	574	
Private consumers by meter, at 7d. per unit	82,197	
		82,771
Quantity used on works	3,822	
„ lost in battery	6,304	
		10,126
Total quantity accounted for		92,897
Quantity not accounted for		2,229
Total units generated		95,126

From this it will be seen that :

	Per cent.
Total efficiency	=91·0
Loss in batteries	= 6 7
Loss in main	= 2·3
	100 0

The total maximum supply demanded was 159,000 watts, which is equivalent to 5,300 30-watt lamps.

THE DOT WALL SOCKET.

The manufacturer of this speciality, Mr. A. P. Lundberg, has recently sent us a sample for inspection. The wall socket and plug illustrated below consist of incombustible material

throughout. The socket is remarkable for its neat and compact design, coupled with good insulation. The over all diameter of the base is only 1 13-16in., while the straight over all, with the plug in position, is 1⅝in. A fuse is provided in the base. The complete fitting is another instance of the pitch to which the manufacture of porcelain has reached. We need only add that the address of the maker is Bradbury-street, Kingsland, N., and that the prices are somewhat in proportion to the dimensions.

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XVI. of new series of "THE ELECTRICAL ENGINEER" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

MANUFACTURING SYNDICATES.

The recent combination of the two largest manufacturing firms in America came as a surprise to all. The firms in question had for years been fighting each other, and the war in prices and between types of machinery had done much to benefit the general public. Now we are assured that the removal of the competition will also be beneficial. This assurance is not in keeping with the history of such combinations in the past. The influence on the few rival firms left to oppose the huge combination now formed is also not likely to be invigorating at first, but we do not doubt that eventually the advantage will rest with the smaller firms. We do not mean by the term small firm that the firm in question is one undermanned and ill-equipped, but rather a firm owned or controlled by one man. Such a firm small enough to be under the thorough control of one capable engineer will always be able to hold its own in manufacture. In the first place, it is untrammelled, and can move more quickly with the times. Then, the dead-weight of over-capitalisation which has to be borne by practically all these large combinations of interests is absent, and the financial problems are correspondingly simple to deal with. The great gain is, however, due to the personality of the control. This pervades all departments, and ensures better work from all concerned. As a gentleman said when referring to the Russian Government, "With an autocratic government, if you can state your case to the autocrat, you either get justice, and get it quickly, or else you never get it, and go elsewhere." So with a firm under autocratic control, the individuals forming the staff are all under personal supervision, and good men get a chance of adequate promotion. The promotion is, in fact, in some degree proportionate to the capabilities of the man in question, and not, as is the case with large syndicates, on his backstair influence. The man with inventive ideas takes his original methods of cheapening the cost of manufacture to the head of the firm, and stands a fair chance of getting some return. With a large combination of interests the financial head invariably gains supreme control, and as a consequence the engineering staff suffers. We even know of a case where the financial element has such a predominating influence that it has fixed a maximum salary, and that a low one, beyond which no member of the staff other than the head of a department shall rise. Such regulation and method of control tend to stagnation, and the members of the staff lose all incentive to excel. It is not, however, only in this way that unduly large concerns suffer. They are almost always under the control of some financial clique, and consequently are run in the interest of this clique. The way in which this interest tends is seldom apparent at first, but it is nearly always disastrous in the long run. It is the old story—either the clique keeps control and bleeds the public and shareholders, or else the shareholders demand redress and get reconstruction after writing off a large proportion of their capital. The abstract question is perhaps not so interesting as the query

Digitized by Google

as to what action the new American syndicate will take over patent rights. They will undoubtedly own the major portion of the patents of recent years dealing with electrical matters. Such of them as are valid they have a perfect right to rigidly enforce. What we object to is the interference with other manufacturers on invalid grounds. Perhaps the different patent law in America may alter the case, but in England it has too often been a case of length of pocket rather than validity of claims. Thus we hear rumours that sole rights for compound winding, the lamination of armature cores, and the use of carbon brushes are going to be claimed. We only trust such rumours are inaccurate, and that the English patents owned by the combination will not be the cause of heavy lawsuits.

THE TELEPHONE IN RAILROAD PRACTICE.*

BY W. W. RYDER, OF CHICAGO.

The growing use of the telephone in railroad work and its present advantages and present possibilities is a subject well worthy of consideration and study. The telephone equipment at local points best adapted to the transmission of the internal business of a railroad depends upon the location and degree of concentration of the offices at each point. The value of a private telephone line connecting intermediate points and the division headquarters along the line of the road is dependent to a large extent upon the number of instruments that are enabled to secure intercommunication thereby. In connection with the speaking-tube or internal telephone system special efforts are being made by the local telephone companies to offer the railroad companies instruments and apparatus that vary with the character of the service desired. For instance—

System A: A central switch with lines radiating from it, each line having one or more stations connected with it, the whole being arranged for intercommunication.—This system is operated in much the same manner as an ordinary telephone exchange, a switch being located at some central point provided with means for calling and receiving calls from each station, and for connecting the several stations with each other. The switch may be located where it can be operated by some person in connection with other work, or if the system is large the services of a regular operator may be required. This system (if but one station is connected on each radiating line) secures secrecy between any two stations, and provides for independent communication between a number of stations at the same time.

System B: A switch at a particular office with lines radiating from it, each line having one or more stations connected with it, the whole being arranged for communication to and from this particular office, but not for communication between stations on different lines.—This system is used for transacting business between a particular office and several stations in cases where it is not required that the stations communicate with each other. A switch is provided at the main office only. This system (if but one station is connected on each radiating line) secures secrecy between the main office and any one of the stations.

System C: A switch at each station, with means for connecting the instrument at such station with lines extending to each of the other stations.—This system is so arranged that a person at any station can call any other station over a special line and establish the desired connection without the aid of an operator. It does not secure secrecy to such a degree as systems "A" or "B." A switch being located at each station access may be had to all circuits whether in use or not, but as the bell at the desired station is the only one operated when a call is made secrecy is fairly assured, and interruptions are not likely to occur unless the use of the same circuit should be desired by a second party, and his instrument be connected for the purpose of making a call. It is possible for parties at several stations to converse independently with each other at the same time.

System D: A single circuit connecting two or more stations.—All instruments being connected upon one circuit no switching apparatus is required. Only two stations can use the line at one time, and there can be no secrecy, as a call made from any station will ring all bells simultaneously.

Systems "A" and "B" are especially adapted and serviceable for freight offices and yards, round houses, switching towers, etc. System "C" is perhaps the most convenient and satisfactory when the stations to be connected are not numerous. System "D" is the most simple and inexpensive.

An outgrowth from system "A" is the present private branch telephone exchange. The benefits derived from the establishment and operation of private branch exchanges seem comparatively unknown, and especially so to those who have not been closely in touch with the growth of this particular line of the business, and it is with a view of arousing interest in this direction, as well as securing additional information through the discussion which I trust will follow this paper, that I have endeavoured to collect as much reliable information as possible bearing upon this subject. This very lack of familiarity with the branch exchange frequently results in a much less efficient service from a given number of telephone lines than would be secured were they merged into the so-called exchange.

"In the march of civilisation the improvements of yesterday are discarded for those of to-day. The tin speaking-tube once used for interior communication gives way to the telephone. In this age, when only time saving is considered more important than labour saving, and the combination of both is the prime object with all active minds, the importance of rapid and reliable communication can not be over-estimated. Especially true is this of the business conducted in a large building where the labour and delay incidental to employing messengers or office boys make an important item of expense. In the general offices of a large railroad company, where every office can be connected one with another, and the various working departments be brought into talking relations with one another, this telephone service is a time, labour, and money saver; and where the heads of departments are separated from each other by doors, stairs, and passages it is invaluable."

Every railroad man is familiar with the general scheme of railroad organisation, and the relationship between the various departments, their chiefs, etc. The lines of authority are closely drawn, and the flow of communication naturally follows these divisional lines. As the division of responsibility among the several officials and employés who carry on the operation of the railway company is plainly defined, so the uses of the telephone tends to parallel those divisions of responsibility and to follow the lines which separate the duties which are to be performed. In the application of the telephone to the transaction of internal business at local points, and within a certain radius of the office building or about the yards and switching centres, the numerous communications necessary are passed to and fro easily and without loss of time. The tendency is toward the constant growth of private branch exchanges, as they give more perfect interchange of communication for every class of business, concentrate the service within certain limits, and enable the business to be transmitted direct without going through the medium of the local telephone operator, and vary the class and extent of the service desired according to the price paid.

The benefits to be derived from the operation of the private branch exchange has been recognised to a greater extent in the city of Chicago than elsewhere in the country. As a matter of fact, there are at present in that city over 130 private branch exchanges, operating an aggregate of over 1,200 telephone instruments. These exchanges are operated by railroad and express companies, large wholesale and retail establishments, manufacturers, etc., and range in extent from four to 100 instruments. They are connected by means of trunk lines with the local telephone company's exchange, so that connections may be had with the public. In a great many cases a particular telephone, while greatly needed for the handling of railroad business, has no occasion for public connection. If arranged so that

* Paper read before the Association of Railway Telegraph Superintendents, Fortress Monroe, Va., June 17.

Digitized by Google

they can secure such connection, the result is that the telephone will be used more or less for private ends, consequently when the public trunk lines are required for legitimate railroad business, they will be reported "busy," while, as a matter of fact, they are being used for private business.

To obviate this evil and to furnish as nearly as possible what is absolutely required, the local telephone company has recently adopted a scheme whereby it is made impossible to give certain offices public connection, although they are able to secure unrestricted intercommunication with every line radiating from the branch exchange. In giving this limited service, the telephone company charges a considerably lessened rental, although securing for the subscriber a more efficient service by not allowing the unnecessary blocking of his down-town trunk wires. This difference in expense, together with the difference in price between public and branch exchange lines, is almost, if not quite, sufficient to pay the salary of the telephone operator even though you have only a small number of lines, and this naturally increases with the greater extent of the system. The success of the system can best be indicated by the statement that of all the branch exchanges put in operation in the city of Chicago, only one has ever been taken out through dissatisfaction with the system, and in this case it was only a short time before the telephone company was requested to immediately replace it, the firm finding that the inconvenience and loss of time were greatly increased when the exchange was closed.

The growth of the private branch exchange system must soon extend along the lines of the individual railroads; in fact, at present the Pennsylvania Railroad Company has in operation a very complete system which gives them direct connection over wires entirely controlled by them between all division headquarters on their road east of Pittsburgh. Through the courtesy of that company I am permitted to exhibit a diagram of this system. They have branch exchanges at all division headquarters, and have leased from the Long-Distance Company necessary wires to complete connections with these points. Other large eastern lines, I understand, are now contemplating the adoption of this same scheme. With the growth of the private branch exchange idea, these exchanges will rapidly multiply in large cities, and the necessity for means of intercommunication between them without going through the public exchange will become imperative; in fact, in the city of Chicago, at present, where branch exchanges are being operated by the Chicago and Northern Pacific, Chicago, Rock Island and Pacific, Chicago, Milwaukee and St. Paul, Chicago and Eastern Illinois, Illinois Central, Chicago and North-Western and Chicago, Burlington and Quincy Railroad Companies, this necessity is very noticeable, and the local telephone company is considering the question of trunking the different exchanges together. With this accomplished, it is but a step to the connection of the branch exchanges in one city with those in another over wires controlled by the railroad companies. How this can best be done can only be decided by trial, and I believe we will have to meet this particular issue at a very early date.

When we consider the rapid growth of the telephone system it seems a question of only a short time before the telegraph will be largely superseded by the telephone. It has been shown in actual practice in commercial service that messages of 30 words can be readily and intelligently transmitted in a quarter of a minute, or 120 words per minute, which is about 3,900 better per hour than the average by Morse, using the Phillips code and the typewriter. The above record is taken from a guaranteed service where the toll service is daily performed on this basis.

The question of the telephone not being able to compete with the telegraph on account of the lack of records was happily answered, you will recollect, by Superintendent Seldon in a paper read before this association at the 1894 meeting, and this feeling, I believe, is rapidly passing away. The despatching of trains by telephone has been tried with perfect success in several instances in this country. This is the most exacting of service, and the fact that it is a success speaks volumes for its efficiency. It is a well-known fact that large corporations are slow in adopting radical changes, but the improvements in telephone apparatus are so marked, and the benefits derived from its use so evident, that they are being forced to recognise its merit, and consequently are rapidly advancing the movement.

THE NAGLO EQUIPMENT FOR TELEPHONE EXCHANGES.—SYSTEM HESS-RAVEROT-WEST.

BY JULIUS WEST.

Amongst those considerations which determine the value of a telephone system, reliability and speed of working are the most important; these two features make it very desirable, even in local systems, to have all the subscribers of one town connected to one single exchange. In the case of interurban systems the need for dealing with all subscribers in one central exchange becomes even more pronounced, in order to minimise the time necessary for making the connections, and thus to utilise as efficiently as possible the expensive trunk lines. This necessity has for some time past induced numerous telephone engineers to look for some means whereby it should become possible, in view of the large increase of telephone systems, to build exchanges of any desired extent. It has been tried to increase the number of possible connections in multiple systems by reducing the size of the constituent spring contacts, in order to accommodate more of these plug switches in a switch-panel, the size of which must be in some proportion to the reach of the operator. It has thus become possible to increase the number of connections in exchanges on the multiple system to about 10,000. This expedient is, however, insufficient, since we have even at present a number of systems larger than this, and as the above-described arrangement embodies some danger to the efficiency of working, it can only be regarded as a partial remedy. The problem has been attacked more effectively by others, who endeavoured to introduce a new principle, by which the number of connections possible could be increased. I refer to the systems of Siemens and Halske, to that of Engelmann, to the "divided board system" (related to the foregoing) which was used at Albany, and to the "express system," introduced rather more than a year ago at San Francisco. These arrangements, which differed more or less from the original multiple system, permit of connecting up a much larger number of subscribers than the limit given above. They all necessitate that the lines must be switched on and interrupted at two points corresponding to the connection of two or more exchanges on the multiple system in a town. They therefore do not offer sufficient advantages to compensate for the saving in line material otherwise effected when establishing several exchanges, although under certain conditions they may, however, prove valuable.

A happy and rational solution of the problem was found by Messrs. G. A. Hess and P. E. Raverot, of Paris, who have invented a new connection for telephone exchanges based upon the principle of arithmetical combinations. In their system the switching operation need only take place at one point, so that we get the improvement desired in working by the combination of all subscribers' wires in a central exchange.

Fig. 1 shows the connections used in the Hess-Raverot combination system. From it, it appears that the subscribers are to be divided into groups which we may for the time denote by the letters of the alphabet. As will be shown later on, these groups may each comprise about 1,000 subscribers. Every group is represented by a number of switch-panels, with one plug switch for each subscriber. Two of these panel boards are combined to so-called subscribers' boards. If we have, for example, four groups, *a b c d*, and place these boards in a row, we get the following combination:

a b ac a d bc b d c d.

Since the wires for group *a* are connected in multiple through the switchboards *a*, those of group *b* through switchboards *b*, etc., the combination boards, as indicated by the above series, enable us to connect two subscribers direct. If, for instance, *a* No. 12 wishes to speak to *b* No. 209, the connection is effected on board *a b* by means

Digitized by Google

of a double cord, and if *a* No. 12 desires to call *d* No. 35 the connection is to be made on board *a d*.

From the combination board the wires lead to the operator's board, where they are represented by a plug switch and an annunciator in such a way that the switches and annunciators of one group form a board, which is divided into several operator tables. When an annunciator drops, the operator can switch himself on to that particular subscriber. For example, *a* No. 12 receives his connecting order—say, *b* No. 209—and has then to transmit this order to that combination board which alone can effect the desired connection, which in this special case would be board *a b*; the transmission of the order "*b* 209 with *a* 12." is made by telephone, and the operator at board *a b* effects the desired connection as usual, and on termination of the conversation interrupts it again.

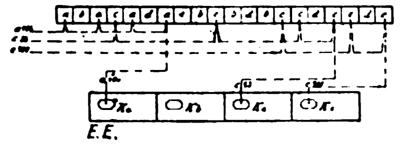

Fig. 1.

It is obvious that the number of these groups may be increased at will without altering the working conditions, and this system thus permits of erecting rationally and quick working exchanges with 50,000 subscribers, and even more.

This method of connection from the very start offered such striking advantages that I considered it advisable to assist in its introduction. I therefore, in connection with Messrs. Naglo and Co., elaborated on this basis a system which is shown on a small scale at the Berlin Industrial Exhibition of 1896, and I propose to describe this system as applied to this experimental exchange.

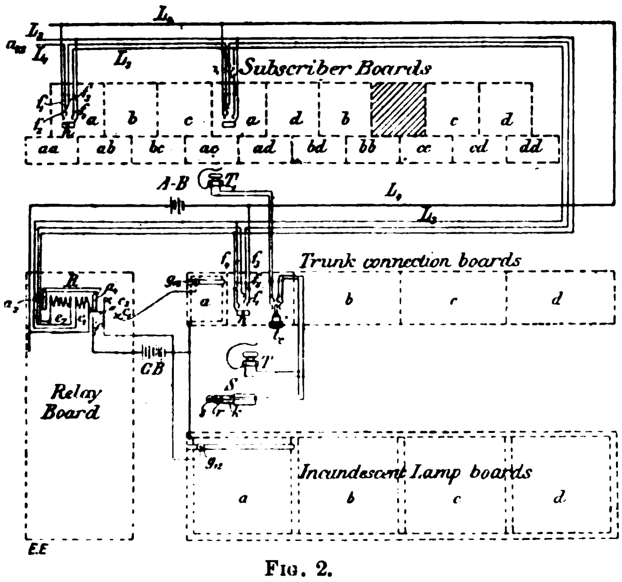

Fig. 2.

If we consider the above row of combination boards as a continuous row of adjoining switch-panels,

a b a c a d b c b d c d,

it is obvious that each letter stands twice at the side of each other letter—*i.e.*, we have *a b* and *b a*, also *a c* and *c a*—so that the connections may be effected in two places, which is superfluous. It becomes thus possible to cut out several letters from the series, and to reduce the above row to

a b c a d b c d,

in which every letter adjoins another but once. For an exchange with five groups we have

a b c a d b e c d e a.

As compared with the series for four groups, an *e* has been introduced between the second *b* and the second *c*. For future extensions provision has to be made from the start; so that the row of boards for four groups ought to be *abcadb-cd*, where the switch-panel—as indicated by the dash (-)—remains vacant, until it is fitted later on with the spring switches for group *e*. For an exchange with ten groups the combinations would be

abcadbecdeafbgcfdgefgahbichdiehfighiakb-ckd-ekf-gkh-ik

which already provides for an eleventh group *l*, so that future extensions may be easily carried out.

This arrangement of the switch-panels makes it necessary to carry all the subscribers' wires along the whole length of the panel rows, and in this respect a limit is very soon reached, when it becomes no longer practicable to carry out this arrangement of the wires, as the number of cables leading through the panels and their length would become unwieldy. When this limit is attained, it will be found of advantage for the proper distribution of the wires to use the arrangement given in the following formula. The original Hess-Raverot arrangement was

ab	*ac*	*ad*	*ae*	*af*	*ag*
	bc	*bd*	*be*	*bf*	*bg*
		cd	*ce*	*cf*	*cg*
			de	*df*	*dg*
				ef	*eg*
					fg

where the *a* cables lead through the upper panel row (vertical row), the *c* cables, however (as indicated by the lines), through the second panel of the first row, then the first panel of the second row, and, finally, through the third row; but, as mentioned before, this arrangement labours under the disadvantage that all the operator fields are twice represented, which may, however, be easily avoided if we combine in a horizontal row, not one, but two letters with the remaining after the formula:

a b c a d b e a f b g a,
c d e c f d g c,
e f g e.

(*To be continued.*)

ALTERNATE-CURRENT TRANSFORMERS.*

BY DR. J. A. FLEMING, F.R.S.

LECTURE II.

The Construction of the Transformer.

In the previous lecture we have examined the general facts connected with the action of the transformer, and we have next to consider questions of transformer construction. The three organs of a transformer being the primary and secondary circuits and the iron core, the constructive problem is reduced to winding these circuits on the core, and properly constructing that core to receive them. We will consider, in the first place, the manufacture of the core. This has to be built up of iron wire or sheet iron, so divided or laminated that eddy currents cannot be set up in it. If it were not for this lamination, the periodic change of induction taking place in the core would set up in the mass of the metal local electric currents which would dissipate energy. Mathematical investigation has shown that, for frequency of 100, or thereabouts, it is useless to make the iron—whether in the form of wire or sheet—less than 1-100th of an inch in thickness—that is, about one-quarter millimetre—and useless to laminate it all, unless the laminations are less than one millimetre in thickness. You will find in the *Electrician*, vol. 28, pp. 599 and 631, investigations by Prof. J. J. Thomson and Prof. Ewing, which deal elaborately with this matter. I have found that their rather complicated formulæ are not fitted for use in the workshop, but that they can for all practical purposes be replaced by a much more simple formula which furnishes all the necessary information for transformer core construction. In the case of good sheet iron, and for the range of induction usually employed in transformer work, which is not more than 3,000 or 4,000 C.G.S. units, that is to say, 30 to 40 microwebers per square centimetre, if we represent the eddy-current loss in watts per cubic centimetre of the plates by a symbol, E; and if we call *t* the thickness of the plate in mils—that is, in thousandths of an inch—and if B is the maximum value of the induction per square centimetre in C.G.S. units, and *n* the

* Cantor lectures delivered before the Society of Arts.

Digitized by Google

frequency, then it can be shown that very approximately $E = \left(\frac{t\,n\,B}{10^8}\right)^2$. Although this is a hybrid formula, containing units of different kinds, and may be horrible to purists, it will nevertheless be useful in the drawing office, and we can simplify it still more if we reckon the maximum induction in webers, and call I this induction per square centimetre, then $E = (t\,I\,n)^2$. In some works it is the custom to reckon the induction per square inch, instead of per square centimetre, and the thickness of the plate in fractions of an inch. If $t_,$ is the thickness of the plate in inches, and $B_,$ the induction per square inch, and $E_,$ the eddy-current loss in watts per pound of plates, then $E_, = \frac{1 \cdot 4}{10^{10}}\,t_,^2\,n^2\,(B_,)^2$. The general custom is to use plates for transformer construction of about ·014in. in thickness, and the standard induction which is generally selected is 2,500 lines of induction per square centimetre, or 2,500 C.G.S. units. This is equivalent to 16,125 per square inch. Under these circumstances, by the above formula it is shown that the loss in watts per pound of plates due to eddy currents would be ·07 watt, the frequency being 100. It may be noted that any increase of temperature as the transformer is worked by increasing the resistance of the iron tends to diminish the eddy-current loss. It will, therefore, be seen that by employing plates of a thickness not greater than 14 mils, eddy-current loss is reduced to a very small amount. One point, however, to which your attention ought to be called is that unless the iron plates are properly arranged, eddy-current loss may exist in them, however thin they may be. If either by reason of magnetic leakage or any other disposition of the magnetic induction, lines of magnetic induction move through the iron in such a manner that their direction is not always parallel to the direction of the lamination of the iron, then under those circumstances eddy currents may be set up in the core which are not hindered by lamination. This source of waste was present in many of the earlier forms of transformer. In addition to the loss of energy caused by eddy currents in the core, there is, of course, that other source of loss called the hysteresis loss, which is due to the magnetisation and demagnetisation of the core, and to the fact that the induction is not in step during the whole period with the magnetising force, but lags behind it. The investigations of Steinmetz have shown that the hysteresis loss in iron sheets can be represented by a simple empirical formula which fits the facts fairly well. It is found that the hysteresis loss per cubic centimetre per cycle in the iron is related to the maximum value of the induction during the cycle by a simple exponential law, and may be, for all practical purposes, closely expressed by the following formulæ :

Let H = hysteresis loss in watts per cubic centimetre,
and H^1 = hysteresis loss in watts per pound ;

then
$$H = \eta\,n\,B^{1 \cdot 65}\,10^{-7}$$
$$= \cdot 0032\,n\,B^{1 \cdot 55}\,10^{-7},$$

where n in the above formula is the frequency, and η is a coefficient called the hysteretic constant, which depends upon the nature of the iron. The value of η may vary from ·002 to ·005. If we reckon the hysteresis in watts per pound, then we have

$$H_, = 0 \cdot 88\,n\,(B^1)^{1 \cdot 65}\,10^{-9},$$

where $B_,$ = induction per square inch.

The exponential constant may vary from 1·55 to 1·6. Thus, for example, if $n = 100$, and if $B_,$, the induction per square inch = 16,125, corresponding to induction per square centimetre of 2,500, then $H_, = \cdot 29$ watt per pound, and $H = \cdot 005$ watt per cubic centimetre. These formulæ have been deduced from experiments made with various kinds of transformer iron; and although they are empirical formulæ, in the sense that they are not deduced from first principles, yet, nevertheless, they are exceedingly useful, and agree so well with experience, that they enable us to calculate the hysteresis loss at any one induction when we know it at another. We may, therefore, put together the two expressions obtained for the eddy-current loss of the hysteresis loss in iron and state that, for all practical purposes and within the limits of the induction usually employed in transformers, the total energy loss in the iron, made up partly of eddy-current loss and partly of hysteresis loss, may be expressed as follows :

T = the loss per watt in cubic centimetres ;
$T_,$ = the loss in watts per pound ;

then
$$T = \cdot 0032\,n\,B^{1 \cdot 65}\,10^{-7} + \left(\frac{t\,n\,B}{10^8}\right)^2.$$

$$T_, = \cdot 088\,n\,(B_,)^{1 \cdot 65}\,10^{-9} + \frac{1 \cdot 4}{10 \cdot 10}\,(t_,\,n\,B_,)^2,$$

where B is the maximum induction in C.G.S. units per square centimetre, and $B_,$ per square inch.

The curves in Fig. 25 show the variation of hysteresis and eddy-current loss in plates of various thickness for a maximum value of the induction of 4,000 C.G.S. units calculated from the formulæ of Prof. J. J. Thomson.

My own experience is that these formulæ agree very well with experience and with the results of measurement. I made some years ago a careful study of the old-form Ferranti transformers, and found a very fairly close agreement between the results of measurement of the core loss in these transformers and the results obtained by calculation from the above formulæ. In specifying for iron for use in transformers, it is now the custom to adopt a standard induction of 2,500 C.G.S. units, or lines of induction per square centimetre ; that is to say, the standard induction is 25 microwebers per square centimetre — and the standard frequency is 100.

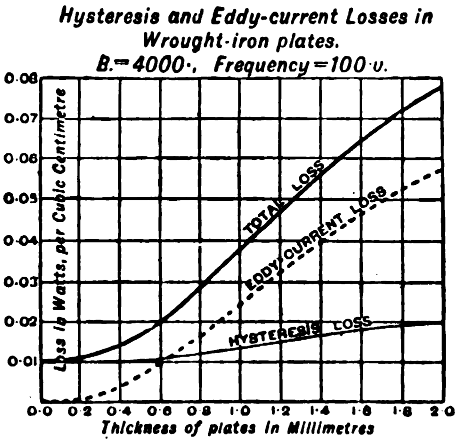

FIG. 25.

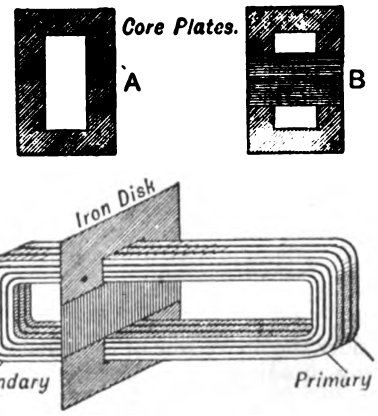
Under these conditions a good transformer iron ought to have a hysteresis loss varying from ·25 to ·5 watt per pound. It is possible under some conditions to get iron with less hysteresis loss than this, but, as we shall see presently, there are some difficulties in keeping it in this condition. Having selected the iron, the next thing is to stamp out the core plates and afterwards to carefully anneal them. It is now well understood that the slightest tooling or handling of iron after it has been annealed hardens it and raises its hysteresis loss—hence the greatest care has to be taken that the plates are not damaged after annealing. The plates have then to be insulated to keep them from electric contact with one another. The old practice was to insulate the plates with thin paper, but paper takes up too much space, and it is now usual to paint the plates with an insulating paint or varnish, which, however, must be able to



Mordey's Transformer.

FIG. 2 .

withstand, without deterioration, the highest temperature which the transformer may reach in work. Even using varnish, the varnish takes about 10 per cent. of the space of the iron. In selecting the iron for the core plates, it is more important to choose an iron with small hysteresis loss than large permeability. These two things are not necessarily connected together. The number of devices which have been adopted for cutting the iron into the core plates, as to avoid unnecessary waste of metal, is very large. In Fig. 26 is shown the manner of building up the core of a Mordey transformer. In Fig. 27 the mode of building up a Westinghouse transformer is also shown. In this case, as in that of the Mordey transformer, where a cross-piece is used, or where there are

Digitized by Google

overlapping iron plates, it is customary now to use packing pieces of sheet iron to fill in the levels, and to get as much iron as possible into the space. In Fig. 28 is shown the method of stamping the core plates from the sheet and constructing the Scott and Addenbrooke transformer. The iron core having been constructed in such a manner as to afford a completely closed iron circuit for the lines of induction due to the magnetising force of the primary coil, the core is then covered with shellaced calico and mica, in order to insulate it from the primary coil; and the greatest care ought to be taken in this respect, because it is not sufficient to insulate the coils

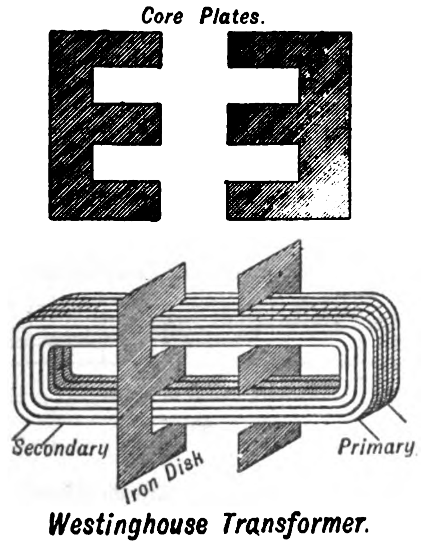


Fig. 27.

of the transformer from one another: they must both be insulated from the core. Thin ebonite is often used as a material for insulating the core, and an indiarubber compound called woodite is a very good material to use. The primary and secondary coils are generally wound on formers; they must be insulated from each other by ebonite or mica, and the primary and secondary coils should be so overlaid or intermingled (as shown in Fig. 29, which represents a typical closed iron circuit transformer) to avoid producing magnetic leakage. In large transformers it is customary to leave a space between the high and low tension coils for the purpose of ventilation, and in the same way air spaces or ventilation spaces have to be left in the iron core. The primary and secondary coils are sometimes separated from one another by a metal shielding plate, which is connected to earth. This is, however, not so good a plan as

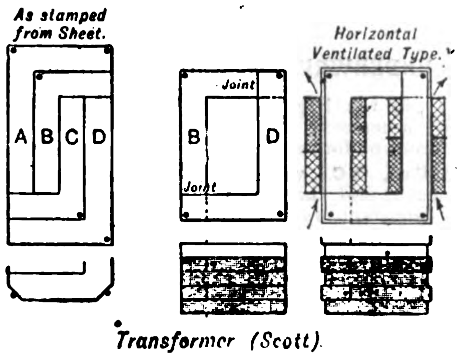

Fig. 28.

an effectual separation of the primary and secondary coils by an insulating shield. In the design of the core it is important to reduce the reluctance of the magnetic circuit as much as possible, in order to produce a large power factor. The term "power factor" is defined as the number representing the ratio between the true power taken up in the core to the product of the primary potential difference and the primary current (root-mean-square values being understood). This product is called the apparent power taken up in the core.

We shall consider in a later lecture the disadvantages of a small power factor. Meanwhile, it may be said that a small power factor in a transformer, when taken at no secondary load, is always an indication of large magnetic reluctance in the magnetic circuit, and hence open iron circuit transformers have always small power factors. The primary and secondary coils, having been placed upon the core and insulated from one another, the transformer is put into an iron case, which is constructed to be watertight. Many manufacturers include in the same case porcelain plates or terminals, to which they attach the extremities of the primary and secondary coils. This, however, is not so good a plan as connecting by a highly-insulated joint the extremities of the primary and secondary coils to highly-insulated cables, which are brought out through watertight glands in the iron case, any necessary connections to fuses or switches being then made outside. In the design of large transformers one important consideration is getting rid of the heat. A transformer ought never to rise above 100deg. C. under any conditions of use, and for every watt which is lost in hysteresis and by copper resistance at least three to four square inches of cooling surfaces must be provided. In the case of very large sub-station transformers, it has even been found advantageous not only to leave ventilating spaces in the core, but to force a draught of air through

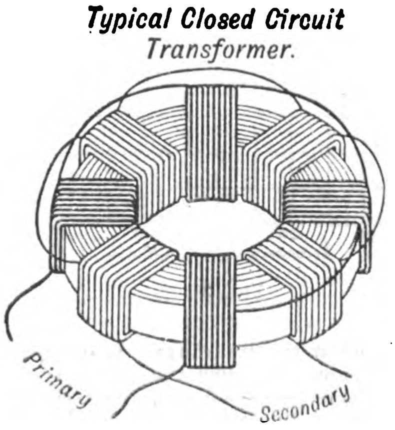

Fig. 29.

the transformer to keep it cool. In some cases a highly insulating oil is put into the case, but the insulation of the transformer must be good enough to work without it. The use of the oil is merely to keep out damp air, and even then it is not always successful in preventing breakdown. The notion that oil could be used as an insulation for transformers, which would heal up again after the passage of a spark or arc, was not confirmed by experience. As regards the general design of transformers, the battle of open *versus* closed iron circuit transformers was fought out and decided long ago. Open circuit transformers—such as the hedgehog transformer—have no

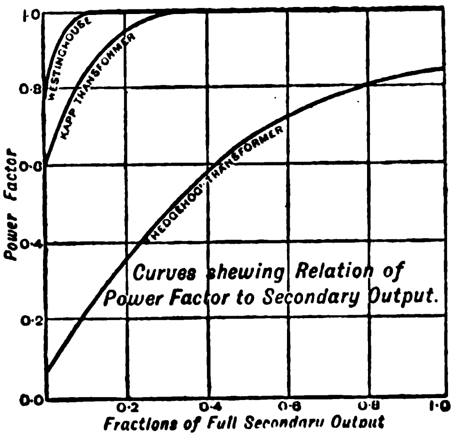

Fig. 30.

advantage over the closed iron circuit transformer in respect of core loss per kilowatt output, and they have a decided disadvantage in a smaller power factor. Moreover, in a closed iron circuit transformer, as the transformer is loaded up, the power factor very soon reaches unity; the curves in Fig. 30 show the manner in which the power factor of several different types of transformer varies as the transformer is loaded up. In a good closed iron circuit transformer, with small magnetic reluctance, a very little loading of the secondary circuit brings the power factor up to unity. In the case of a six-kilowatt Mordey transformer I found that, loading up to 1-60th of full load, brings the power factor up to unity. The advantage of large power factor means that we have a small root-mean-square value in the magnetising current at no load, and, therefore, a small heating loss in the main supplying the current of that transformer. When the transformer is at work we not only have energy losses going on in the iron, but at the same time we have energy losses in the

Digitized by Google

copper, called the copper losses, which are due to the resistance of the copper circuit. It can be shown the most advantageous ratio between the copper losses and the iron losses is to so construct the transformer that at full load the total copper losses are equal to the total iron losses. In very large transformers, where the secondary circuit consists of very thick copper bands or wire, if magnetic leakage exists to any sensible extent, we may have eddy-current losses set up in the copper circuits, and this, in addition, may be a source of energy waste. The copper resistance operates not only to cause a large energy loss, but partly to account for what is called the secondary drop of the transformer. If a transformer is connected to a constant-potential primary circuit, and if the secondary circuit is gradually loaded up, the potential difference between the secondary terminals is less when the transformer is fully

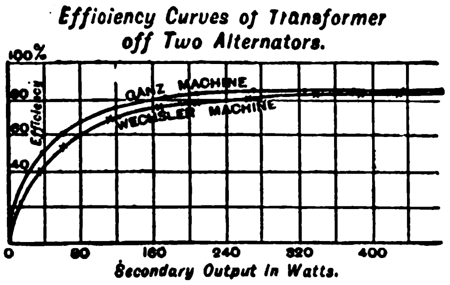

Fig. 31.

loaded than it is when the transformer is on open secondary circuit. This difference is called the secondary drop. This drop is due to three causes—firstly, the resistance of the primary circuit; secondly, the resistance of the secondary circuit; and, thirdly, to magnetic leakage. As far as regards the copper resistance, we may calculate the secondary drop by the following formula :

$$\text{Secondary drop} = \frac{100 \times (C_1 - \textit{mag. cur.})\, R_1}{E_1} + \frac{100\, C_2\, R_2}{E_2},$$

where C_1 is the R.M.S. of the primary current;
C_2 is the same value for the secondary current ;
R_1 is the resistance of the primary circuit ;
R_2 is the resistance of the secondary circuit ;
E_1 is the difference of potential between the primary terminals ;
E_2 is the difference of potential between the secondary terminals ;

taken when the transformer is on open secondary circuit, and the symbol *mag. cur.* stands for the magnetising current of the transformer—that is, the primary current when the transformer is on open secondary circuit.

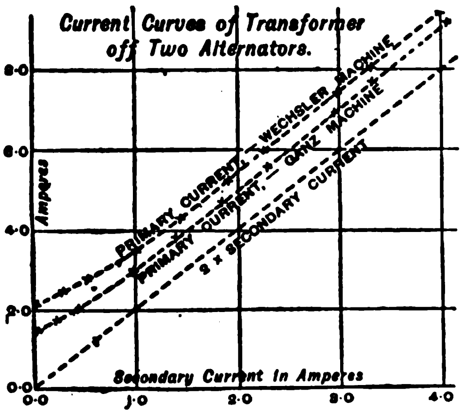

Fig. 32.

This formula, however, only gives us that part of the drop which is due to the copper resistances ; the actual observed drop would be greater than this by an amount due to magnetic leakage.

In dealing with the testing of transformers in our next lecture, we shall discuss the method by which this drop may be measured. In considering the action of transformers, it is important to notice that the iron core loss of the transformer, the secondary drop, and the power factor of the transformer at no load are all greatly affected by the form of the curve of primary E.M.F. It is the custom sometimes to speak of the core loss of a transformer as if it were a quantity inherent in the transformer itself, and which could be exactly specified for any particular instrument. As a matter of fact, this is not the case. Experiments carried out with different transformers worked on different alternators by Dr. Roessler in Germany and by myself in England, have abundantly demonstrated that the form of the curve of primary E.M.F. has an immense influence on all the above-mentioned quantities. Dr. Roessler employed two machines— one a Wechsler and the other a Ganz alternator. When these machines are running on open circuit, the Wechsler alternator gives a curve of E.M.F. which has a well-rounded form ; whereas the Ganz machine has a curve of E.M.F. which has a very sharp or peaked form. The machines I chiefly employed in my own experiments were the Mordey alternator, the Thomson-Houston alternator, and a Ferranti machine. The form of the curves of E.M.F. of the first two named machines, under various conditions, have been shown in Lecture I. The general effect of all these experiments has been to demonstrate that when a transformer is worked off an alternator giving an E.M.F. curve with a very sharp or peaked form, the effect of this is to make the iron core loss less, and the secondary drop greater, than it is if the same transformer is worked off an alternator having a curve

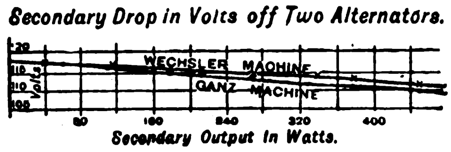

Fig. 33

of E.M.F. with a rounded or square-shouldered form. If, therefore, we draw an efficiency curve for a transformer, that efficiency curve giving the efficiency—that is to say, the ratio between the watts delivered from the secondary to the watts taken in on the transformer circuit—and express this efficiency in terms of the fractions of the secondary load of the transformer, the form of that efficiency curve will be affected by the nature of the machine which is supplying the primary current. In Figs. 31, 32, 33 are shown curves illustrating the effect of the employment of different alternators on the same transformer in affecting the efficiency, primary current values, and secondary drop of any given transformer, when taken on open secondary circuit.

For fuller information on this point the reader is referred to the treatise on the "Alternate-Current Transformer" (vol. i., chap. vi., new edition), by the present writer, which will supply more details on this question than we have space to consider here.

LEGAL INTELLIGENCE.

UNDERWRITING A SHARE ISSUE.

On Monday, in the High Court Division, before Mr. Justice Lawrance and a common jury, the case of Holophane, Limited, *v.* Hesseltine came on for hearing.

Mr. C. McCall, Q.C., who appeared, with Mr. Fox, for the plaintiff company, said the question to be decided by the Court was whether defendant was a shareholder, and should be held as liable for shares in respect of which his name stood at present upon the register. The number of shares allotted was 320, and the amount in which defendant was alleged to be liable was £240, and the Court would have to decide whether he was properly on the register, and therefore liable. The company was formed in the month of February last to purchase a patent and carry on the manufacture of gas and lamp globes, and the word which had been adopted as the title of the company was one which, according to its derivation, was perfectly clear. The globes were made so as to absorb less of the light than ordinary glass globes, or, in fact, of any other kind. That was what the patentee claimed, and there were those who believed that these globes had a great future before them. The company was registered on February 19, and early in the month of March a Mr. Smith, who was a solicitor in the City and who had acted as solicitor to the defendant, called upon him. He was then acting for the patentee, a Mr. Mygatt, and they entered into certain underwriting arrangements. Mr. Hesseltine knew perfectly well what he was about, and he was getting a commission of 15 per cent. and ran the risk of having to take up 500 shares if the public did not subscribe at all. The public subscribed only about half of the capital. During the negotiations a form of application was sent in by the defendant unsigned, and ultimately defendant received a communication stating that the public had subscribed £12,600, leaving the underwriters' liability at sixteen twenty-fifths—namely, the balance of 320. After application had been made to the defendant on several occasions to fill up an application form, and no answer having been received, application was made

Digitized by Google

for the money due. Some correspondence ensued, and in April the 320 shares were allotted to defendant by the directors, and in the course of further correspondence defendant wrote that he objected to having the confidence trick played upon him. The defence was that the defendant had been induced to enter into the contract by misrepresentation. There was no case for the plaintiff, as no application forms had been signed by the defendant. Evidence was called, the case ultimately resolving itself into a question whether a Mr. Mygatt was authorised by the defendant to sign an application for him.

The case went over to Tuesday, and ultimately his Lordship directed a verdict for the company, and allowed leave to appeal.

WESTMINSTER AND VANCOUVER TRAMWAY COMPANY.

Last week, before the Judicial Committee of the Privy Council, the Court being constituted of Lord Hobhouse, Lord Macnaghten, Lord Davey, and Sir Richard Couch, the case of the Edison General Electric Company *v.* the Westminster and Vancouver Tramway Company, the Bank of British Columbia, and others, came on for hearing. It was an appeal from a judgment of the Supreme Court of British Columbia of January 30, 1896, affirming a decision of Mr. Justice Crease.

The Hon. Edward Blake, Q.C. (of the Canadian Bar), and Mr. John D. Crawford appeared for the appellants; Mr. C. Robinson, Q.C. (of the Canadian Bar), and Mr. Bray for the respondents, the Bank of British Columbia.

The appellants, who were the plaintiffs in the action, on behalf of themselves and other creditors of the tramway company, alleged that they had, on December 29, 1893, recovered judgment against the company for 18,470dol. and costs, and that they had been deprived of the fruits of that result by a judgment obtained on January 24, 1894, by the Bank of British Columbia against the tramway company for 261,217dol. and costs, which judgment they alleged was the result of collusion by the tramway company (then insolvent) with the bank, with intent to give the bank a preference over the other creditors. The respondents denied the collusion and the intent alleged, and stated that the judgment was given for a debt due by the tramway company to the bank and under pressure exercised by the latter. The action was tried before Mr. Justice Crease without a jury, judgment was entered for the respondents with costs, and the Supreme Court affirmed that decision.

At the close of the arguments their Lordships did not call on the learned counsel for the appellants for a reply, but said they would deliver judgment at a future sitting.

WILLANS AND ROBINSON'S PATENTS.

The petition for the prolongation of one of the Willans and Robinson patents was heard by the Judicial Committee of the Privy Council on Wednesday, the Court being constituted by Lord Watson, Lord Macnaghten, Lord Shand, Lord Davey, and Sir Richard Couch.

The patent was one granted to Peter William Willans, deceased, and Mark Heaton Robinson, dated October 14, 1882, for an invention of "improvements in high-speed engines," and consisted in the use of a cylinder containing air, in which a piston moved which was connected to the heavy moving parts in order to control them.

Mr. Moulton, Q.C., Mr. Roger Wallace, Q.C., and Mr. J. C. Graham appeared for the petitioners, Messrs. Willans and Robinson, Limited; and the Attorney-General and Mr. Sutton for the Crown.

The **Attorney-General** submitted that sufficient remuneration had been received in respect of the patent, and **Lord Watson** intimated that their Lordships were unable, on the materials before them, to come to the conclusion that the remuneration received in respect to the patent had been inadequate, and they would accordingly advise her Majesty that the petition ought to be refused.

COMPANIES' MEETINGS AND REPORTS.

CROMPTON AND CO., LIMITED.

The annual meeting of this Company was held on Monday at the Cannon-street Hotel, E C., Mr. John Trotter presiding.

The **Chairman** moved the adoption of the report and accounts. The first portion of his speech was practically a *résumé* of these, which have already been given in our last week's issue. Owing, said the speaker, to the fire at the Chelmsford works last November, by which all the books and records that were in the offices had been destroyed, it had been found impossible this year to prepare any profit and loss account. That being so, the directors had taken counsel with their advisers, and the conclusion they had come to was that the only plan that seemed feasible to adopt was to have a valuation of the shareholders' property as it stood, and make a fresh start. The freehold property had been valued by Mr. Whitmore, of Chelmsford, and the plant by their managing director, Mr. Crompton, assisted by Mr. Brunton, the works manager. The result was before the shareholders. The fire destroyed a large portion of the buildings and works at Chelmsford, as well as the stock and electric light plant. There did not seem to have been any serious, if any, loss directly in consequence of the fire; but the indirect loss to them had been very serious, the business practically stopped, and the cost of manufacturing everything was enormously increased. The effect of this was clearly shown in the balance-sheet, a sum to the debit of revenue account being shown of £10,051, which, he thought he might say, was directly traceable to the fire. It had been decided to build new works as speedily as possible, and a site for the purpose had been obtained near Chelmsford, close to their present works. The Chelmsford lighting would in the future be quite distinct from the general manufacturing business of Crompton and Co. It was also clear that works of more than one storey with heavy machinery would not do. In future they would have one storey only, so that heavy tools would not come tumbling down and doing more damage than the fire itself. The new works would be constructed, so far as possible, of uninflammable materials, and the offices would be separate. The policy of the Board in the immediate past had been to endeavour to concentrate the business and get rid of outside excrescences. Their branch at Hove had been sold, and the cooking department at Lilley-road had been reorganised and the expenditure on it cut down, and efforts had been made to dispose of it. Mr. Albright had been looking for business in Australia, and other directors had been pressing it at home. At present they had as much as they could deal with. There were several assets in the accounts which might be described as non-realisable, and there was the item of £30,000 for goodwill. He thought it would be a good thing if some scheme could be devised by which some of the items might be written down or written off, and the suspense account must be dealt with. Unless this was done he did not see how they were to pay a dividend. His colleagues agreed with him that it would be desirable to take the whole matter into serious consideration, and see if some scheme could not be formulated under which the interests of the various shareholders and the debenture-holders would be equitably dealt with.

Mr. R. E. B. Crompton seconded the resolution. The disaster that had happened to them in their fire had been pretty bad, but things might have been much worse if it had not been for the splendid efforts of their staff. In these days of close competition shareholders would appreciate the difficulty of manufacturing at a profit with their plant separated and divided in temporary premises. What had been done at Chelmsford was to lower the walls to the level of one storey and put on a temporary roof, under which they had worked up to the present. They hoped to have a considerable portion of their new works roofed in three months, and, perhaps, to begin work in part of them in four months. They had before them good prospects of work, and they had been taking orders at prices which were encouraging. Had it not been for the fire he believed they would have done well on the year, and it was a bitter disappointment to him personally to find the results of their efforts swept away.

The report and accounts were then carried unanimously.

On the motion of **Mr. Crompton**, seconded by **Mr. Tufnell, sen.**, the confirmation of the election of Mr. J. Trotter as chairman was passed, Mr. Carlton Tufnell was re-elected director, and the auditors (Messrs. J. H. Duncan and Co) were also re elected.

In moving the vote of thanks, **Mr. G. Kitchen** expressed the satisfaction of the shareholders at the intention of the Board to a face consideration of the financial state of the Company. **Mr. Slater** seconded the vote, and the proceedings ended.

CITY AND SOUTH LONDON RAILWAY COMPANY, LIMITED.

The half-yearly general meeting of this Company was held on Tuesday at Winchester House, Mr. C. Grey Mott (chairman) presiding.

The **Chairman**, in moving the adoption of the report and accounts, an abstract of which appeared in our last issue, said that their experience had shown that there was no railway in existence that could boast of more punctual, convenient, and safe working than could the Electric. He then referred to the accounts, and, beginning with the capital, remarked that during the half-year there had been received on capital account £3,000 in respect of preference shares issued, £7,531 for debenture stock, and in premiums on those shares and stock £3,780. They had spent in various new works, rolling-stock, and improvements £3,280; terminable debentures had been paid off to the amount of £8,400; they had an increased balance at the bankers of £964, and had reduced their outstanding liabilities by £1,666. The amount of capital authorised had been considerably increased, because at the last meeting they created new capital under the Act of 1893. As regarded the revenue, the receipts from passengers showed an increase of £328. There was a small decrease in season tickets, but there was an increase in parcels, rents, and sundry accounts, the net increase being £500. The expenses of maintenance, on the other hand, showed an increase of £180, due to their having charged £150 of the cost of altering King William-street Station against revenue. Locomotive and generating power showed a decrease of £250; carriage repairs an increase of £100, which with other minor charges made a net decrease of £18 in the expenditure. Their net increased receipts were £509, and the net decreased expenditure £18, making £527 to the good. They had decreased debenture interest £300, and increased preference dividend £180, and they proposed to declare an increased dividend of ¼ per cent., absorbing £780. The working expenses had been 60·02 against 61·55 last half-year, a decrease of 1½ per cent.; the receipts per train mile 2s. 2¼d., against 2s. 2¼d., showing three-tenths of 1d. improvement. The receipts per passenger were 1·87 against 1·82—the largest receipts they had had since the first half-year, when they charged a uniform 2d. These receipts were steadily growing. The locomotive expenses per train mile had been 5·80d., against 6·10d., and if they deducted

Digitized by Google

the carriage of coal, in order to make a comparison with the large railway companies, the locomotive expenses per train mile were reduced to 4½d. With reference to the passenger traffic, the largest number they ever carried was in the June half of 1894—namely, 3,383,154. They were then so overcrowded that they raised their fares. In the June half of 1895 they carried 3,113,000, but that number had since been steadily increasing until in the past half year it rose to 3,192,000. Therefore, notwithstanding the increased fare they had been charging, the number of their passengers kept steadily increasing, and the amount received on the number carried last half-year was £24,021, whereas they only received £23,564 on the increased number carried in the June half-year of 1894. They might look forward to the time when their charges might be reduced with the very large accession of traffic they would have in the future when they got their extension opened, and so were prepared to deal with it. He considered that the future of their undertaking was very hopeful. The alteration at the King William-street Station had enabled them to run considerably more trains and to give increased accommodation, but it only afforded a temporary relief. He told them last year that they contemplated putting down a condensing plant, in order to save considerably in their fuel consumption, and it was now hoped that this would be at work in two or three months' time; but it was somewhat of a novelty in this country, and they had to proceed with it very carefully. As to the extension of the three sites it would be necessary to acquire for the Moorgate-street line, the purchase of one had been arranged for, the second was under negotiation with a prospect of its being very soon concluded, while the third was the church site, about which they had been very much harassed and put to needless expense, mainly because their opponents did not appear to know their own minds as to the Church of St. Mary Woolnoth and what should be done with it. The Bill was still before Parliament; but they hoped in the course of a few days to get some satisfactory settlement of the whole matter sanctioned by Parliament. At their last meeting the shareholders authorised the issue of 20,000 5 per cent. perpetual preference shares for the purpose of paying for this extension. These shares had been taken up since the end of the half-year on satisfactory terms. At the time he had thought that these shares would rank *pari passu* with the existing preference shares, but it was found that it could not be so, and that had not made the issue so easy. This had been accomplished on such terms that the interest on the shares would not be payable for three years from now. They would therefore have time to complete their line without the existing revenue being trenched on for dividend on the additional preference shares until the extension was open and earning money to pay it. He concluded by moving the adoption of the report.

Mr. S. Hanbury seconded the resolution.

Mr. Drake congratulated the directors on the report.

Mr. Jeffreys enquired as to the loss of season ticket holders, the increase of assessments, and the issue of debentures and preference shares. He could have wished the shareholders to have had an opportunity of taking some up.

The **Chairman**, in reply, said that the decrease in the season-ticket holders was simply the result of an alteration in the fares at one of the stations. The Company carried the passengers and got the money just the same, but some of the passengers preferred to pay daily. With regard to the question of rating, he was sorry to say that the last quinquennial valuation resulted in a considerable increase in their assessment, and although they had since appealed against the assessments and done their best to get them reduced, they had not succeeded. The matter, however, would always have the careful consideration of the Board. As to the issue referred to by Mr. Jeffreys, he did not think it would have been possible for many of the shareholders to have taken it up in the form it had been issued. It had been mainly taken by several wealthy gentlemen, who intended to hold it and not to bring it on to the market at present.

The resolution was carried unanimously.

ANGLO AMERICAN TELEGRAPH COMPANY, LIMITED.

The half-yearly general meeting of the Anglo-American Telegraph Company, Limited, took place on Friday last at Winchester House, E.C , the Marquis of Tweeddale (the chairman) presiding.

The **Chairman**, in moving the adoption of the report, an abstract of which appeared in our last issue, said the notable feature was the increase in the traffic receipts, which amounted to £11,916. This was due to the revival which had taken place in trade, and which had been going on for some time. The Presidential election campaign, no doubt, had a disturbing effect on business, and when that important matter was disposed of, and the United States' financial policy placed on a more stable basis than at present, they might look forward with confidence to an increase in their earnings. The renewal fund had now reached the respectable figure of £651,700, and the market value was, he believed, £100,000 more, so that they were making tolerably rapid progress towards the million they had so often talked of in connection with their renewal fund. He thought they might consider that they had come through the ordeal of the International Telegraph Conference satisfactorily. With reference to the litigation respecting the French cable, they would remember that the directors appealed from the decision of the French Court, which was favourable to them to a certain extent, but not sufficiently so. The Company's case was lodged last April in the Chamber of Requests of the Court of Cassation, or final Court of Appeal. The Chamber had the power of refusing to allow an appeal. The consideration of the papers rested entirely with the officials of the Court, and nothing the Company could do would expedite the hearing. The result of their operation for the half-year was the considerable increase in their dividend of 3s. per share.

Mr. F. A. Bevan (deputy-chairman) seconded the resolution.

A discussion followed, and in reply to questions the **Chairman** said he felt sure they would be able to recover the costs incurred by them in connection with the French litigation, but the object of their appeal was to recover a much larger sum. He considered that it was quite compatible with the interests of the Company that he should be chairman of the Eastern Telegraph Company also. It would tend to smooth any friction which might arise between them. Neither the Eastern Company nor the pooling companies had any interest in promoting a cable to America by the Azores. The concession for the German cable was originally very different from what it was now. They would hear nothing of it, he believed, for some years to come with the exception of the opening of the line from Germany to Spain, and this was entirely with a view of giving the Germans better communication to the East than they at present had. As to the renewal fund, one of the cables was comparatively new and strong, but the others were old, and they must look forward to the time when it would be necessary to renew them or to put in many miles of new cable. Their share in the pool depended on their maintaining three cables for certain. When governments took to subsidising cables in competition with those working on commercial principles it was a serious matter, but they could not prevent the French Government or the German Government from giving subsidies.

The resolution was ultimately carried with four dissentients.

DIRECT UNITED STATES CABLE COMPANY, LIMITED.

The ordinary general meeting of this Company was held on Tuesday at Winchester House, E.C., Mr. E. M. Underdown, Q.C., presiding.

The **Chairman**, in moving the adoption of the report, an abstract of which appeared in our last issue, said the half-year's revenue, after deducting out-payments, amounted to £42,456, as compared with £37,653 for the corresponding period of 1895. The working and other expenses, including the cost of repairs to cables, amounted to £19,692, leaving a balance of £22,764 as the net profit of the half-year. This had been appropriated in paying three quarterly interim dividends amounting to £19,730 during the financial year and a final payment of 2s. 6d. per share was now proposed, making, with the three interim dividends, 2¼ per cent. for the year. During the past year there had been an increase of nearly 13 per cent. in the revenue as against an increase of 4 per cent. in the working expenses. After referring to the death of the late chairman, Sir John Pender, Mr. Underdown added that the Company was working with the utmost friendship and co-operation with the Western Union Company, and their relations with the Anglo-American Company were extremely satisfactory. Their relations with the Government were also satisfactory. Some years ago representations were made by their late chairman to the Colonial Office as to their not getting the messages from the Bermuda company which they ought to receive, and an answer was given which he did not consider satisfactory. He was now glad to say that he believed they would in future have their proper share of the messages. They had only one cable against a total of 11, and taking all things into consideration the share they had of the traffic was a very satisfactory one. With reference to the question of the reserve fund, their cable was getting respectable from its age. It had held out in a remarkable way, but they must be prepared for contingencies. In order to retain their share in the pool, they must have a perfectly good cable, and they ought not to be contented until their reserve fund amounted to a sum which would replace their cable if it were to break down. He was glad to say that their traffic in the current half-year still continued to show improvement.

Mr. James Pender, M.P., seconded the motion.

In answer to **Mr. John Newton**, the **Chairman** stated that he had not for a moment intended to suggest that their cable was at all in an unfavourable state; its condition was so good that it could be worked duplex.

The motion was unanimously adopted, and also a resolution of sympathy with the family of Sir John Pender.

GLOBE TELEGRAPH AND TRUST COMPANY, LIMITED.

The general meeting of this Company took place on Tuesday at Winchester House, E.C., the Marquis of Tweeddale presiding.

After referring to the death of the late chairman, Sir John Pender, the **Chairman**, in moving the adoption of the report, a summary of which was given in last week's issue, stated that the receipts for the past year, after paying all expenses, had been £185,223, showing an increase of £5,758 over the receipts of the previous year. This increase was owing to the fact that they had received better dividends from several of the companies in which they held investments, so that they were able to recommend that day a dividend on the ordinary shares of 4½ per cent. for the current year, which was ⅜ per cent. better than that for the previous year. In future, interim dividends would be paid on October 31, January 31, and April 30 in each year. The reason for this was easily explained by the fact that one of the companies in which they held a considerable investment now paid its dividends about a week later than they did before. Their holding in the Anglo-American Company was very large, and a small percentage of

Digitized by Google

increase in the dividend of that company made a considerable difference in the amount received. During the past year they had reduced some of their holdings, and had distributed the amount realised among four or five different companies. In doing this they had reinvested the proceeds in such a way as to secure for the shareholders a higher rate of dividend.

Mr. James Pender, M.P., seconded the resolution, which was carried unanimously.

NATIONAL TELEPHONE COMPANY.

The annual meeting was held yesterday afternoon at Cannon-street Hotel, Mr. J. S. Forbes in the chair.

The **Chairman** moved the adoption of the report and accounts, which we published in our last issue, and proposed a dividend at the rate of 6 per cent. per annum on the first and second preference shares, 5 per cent. on the third preference shares, and 5 per cent. on the ordinary shares, all less income tax

The motion was adopted.

A fuller report of the meeting will appear in our next issue.

BRISTOL TRAMWAYS AND CARRIAGE COMPANY, LIMITED.

The following is the report of the directors to be presented to the shareholders at the ordinary general meeting to be held at the Grand Hotel, Broad-street, Bristol, on August 6, 1896, at 1 p.m. :

The gross receipts for the half-year amount to £54,456. 14s. 9d., and the working and general expenses and renewals are £42,810. 8s 6d., leaving a net balance of £11,646. 6s. 3d , which it is proposed to appropriate as follows :

Interest on 4 per cent. mortage debenture stock ...				£1,735	13	10
Dividend at the rate of 6 per cent. per annum (free of income tax) for the half-year ended June 30 ...				7,500	0	0
Balance carried to reserve and renewal funds—viz. :						
Leased premises redemption	200	0	0			
Electrical renewals	974	5	8			
Contingencies	1,236	6	9			
				2,410	12	5
				£11,646	6	3

The receipts from the tramways department show an increase of £11,651, and the carriage department returns a decrease of £155. The total number of passengers (excluding postal riders) carried during the six months on the Company's cars and omnibuses was 8,361,163. The provisional order granted by the Board of Trade authorising the construction of tramways at and near the tramways centre, the short extension of the Kingswood tramway, and the use of electricity on the Eastville line, has been confirmed by Parliament. These tramways have been constructed, as also doublings on the Horfield and Bedminster lines ; the extension of the latter section, together with the conversion of the Eastville line, is being proceeded with. A contract has been arranged for the electrical equipment of the Eastville line, as also for the necessary additions to the plant and machinery at the St. George's power station, and the directors anticipate that these will be completed and the Eastville line worked by electric traction during the current half-year. The directors are pleased to report that the St. George and Kingswood electric line has been worked with great satisfaction to the public, who much appreciate the improved facilities and reduced fares on this portion of the Company's system. It is intended to apply in the ensuing session of Parliament for powers to use electricity on the other portions of the undertaking, as also to extend the tramways in various districts. Full details will in due course be submitted for the consideration and approval of the shareholders. In the meantime, as additional capital is necessary for carrying out the works now in progress, a resolution will be submitted at the ensuing meeting to authorise an increase in the share capital. The extent to which the shares to be created will be called up entirely depends upon the Bristol Corporation being prepared to consent to the improvement and extension of the system upon such terms as the directors can properly recommend for acceptance by the shareholders.

CHILI TELEPHONE COMPANY, LIMITED.

The report of the directors of this Company for the year ended March 31 last states that the aggregate number of subscribers at all centres at the end of the year was 4,252, as compared with 4,015 at the beginning, or a gain of 237 for the year. The gross revenue from all sources for the past year compares favourably with that of the previous one. In 1895-96 it was 619,826dol., in 1894-95 it was 555,551dol.—an increase of 64 275dol. The expenditure in Chili during the year was 384,979dol. ; in the previous year, 364,477dol.—an increase of 20,502dol. The net income in Chili from all sources was in 1895-96, 234,846dol. ; in 1894 95, 191,074dol.—an increase of 43,772dol. The average rate of exchange for the year was 17·27d., as compared with 13·61d. in the previous year, giving an increase for the year of 3·66d. Converted into sterling at these rates, the net income in 1895-6 was £16,903 and in 1894-5 £10,835, or an increase of £6,068. The increase in the value of the liquid assets over liabilities in Chili, due to the rise in exchange, amounts to £351, which has been carried to reserve. The net profit of the whole business in 1895-6 was £8,551 and in 1894-5 £6,013, an increase of £2,538. In addition to the amount mentioned, the sum of £3,295 has been carried to reserve, raising it to £15,500. The directors recommend the payment of a dividend of 4s. per share, being at the rate of 4 per cent. per annum leaving £558 to be carried forward. During the year the capital outlay in sterling was £3,833 ; the total mileage on March 31, 1896, was 6,722 miles, as against 6,420 in 1895—an increase of 302 miles. The general meeting is on August 7.

EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY, LIMITED.

Directors : James Staats Forbes, Esq (chairman), the Earl of Lichfield, Major Samuel Flood Page, Joseph Wilson Swan, Esq., F.R.S . Ernest Villiers, Esq.

Thirteenth annual report of the directors for the business year ending June 30 1896 :

The profit and loss account, after writing down considerable amounts for depreciation of plant and stock, shows a credit balance of £27,526. 12s. 9d. Providing for the interest accrued upon the £100,000 debenture stock, there remains a balance of £23,026 12s. 9d. available for distribution An interim dividend at the rate of 5 per cent. per annum having already been paid in respect of the first half-year ending December, 1895, a further payment at the rate of 5 per cent. per annum, in respect of the second half is recommended ; the balance of £5,352 14s. 9d. being carried forward. Notwithstanding the severe competition now existing in the trade, the volume of business during the past year has been larger than in any former period, but the increase in the cost of material and labour, the lowering of the sale price of many articles, and the check to the Company's manufacture consequent upon the strike at the Ponder's End Works in the early part of the book year, have necessarily somewhat adversely affected the results of the year's working. The final meeting for winding up the Swan United Electric Light Company, Limited, was held on December 17, 1895, and the liquidation thereby completed. Major Flood Page and Joseph Wilson Swan, Esq., F.R S., retire by rotation from the Board, and offer themselves for re-election. Messrs. Welton, Jones, and Co., the auditors, offer themselves for re election.

Profit and Loss Account for Year ended June 30, 1896.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Odessa.—The Municipal Authorities will receive tenders up to August 13 for street electric lighting and for the lighting of the new prison.

Nava del Rey (Spain).—The Municipality are open to receive tenders up to August 28 for the electric lighting of Nava del Rey for a period of 20 years.

Bucharest.—Tenders are wanted by August 19 for the electric lighting of the Boulevard Coltea. Application should be made to the Mairie, at Bucharest.

Mons.—Tenders are required for the construction of an electric generating station building for the Tournai Asylum. Particulars at Brussels, rue des Augustins 17, and tenders will be received up to August 3.

Vich (Spain).—The contract will be allotted by the municipal authorities of Vich on August 17 for the electric lighting of the town for 10 years from June, 1897. The annual payment proposed is about £800.

London, E.C.—Among other stores, the Great Indian Peninsular Railway Company are ready to receive tenders by August 6 for "telegraphic materials." Particulars are obtainable at the offices, 48, Copthall-avenue, E.C.

Halifax.—Firms desiring to tender for the electric lighting and hoists at the new infirmary to be built for the Guardians of the Halifax Union must apply before August 13 to the architects, Messrs. Horsfall and Williams, George-street. and deposit two guineas with the Clerk to the Guardians, Union Offices, Halifax.

Hapton (Padiham, Lancs.).—Tenders are wanted for lighting Hapton township with electricity from September 1, 1896, to April 30, 1897, for the Parish Council. Endorsed tenders should be sent to Mr. E. O'Shaughnessy, clerk, St. Anne's-terrace, Padiham, by August 3. Full particulars can be obtained on application to the clerk at that address.

Simla (India).—The Municipality is inviting tenders for lighting by electric light for a term of years the principal thoroughfares and buildings belonging to the Municipality. Tenders must be submitted by September 1 next. Should any proposal be accepted, the Municipality will afford the successful tenderer all facilities to extend the system of lighting to private houses.

Cologne.—Tenders are required by the Municipal Authorities for the construction and working of electric tramways in the city of Cologne to an aggregate length of 20·3 kilometres (12½ miles). Specifications, plans, and particulars are obtainable for 10 marks (10s.) from der Registrateur B, des Oberbürgermeisteramt, Köln, Germany, and tenders must be in by November 6.

Madras.—Tenders are invited for the lighting by electricity of Government House, Madras, including the banqueting-hall and aide-de-camps' bungalow, and also for the lighting of Government House, Guindy, including the military secretary's bungalow. For particulars application must be made to the consulting architect to the Government, Chepauk, Madras. Tenders will be opened on November 11, 1896.

Voghera (Italy).—In view of the expiration of their contract with the local gas company in 1898, the municipal authorities of Voghera are desirous of receiving during the present year propositions for the lighting of the town either by the electric light or a mixed system of gas and electricity. The population is 16,000. Application should be made to L'Administrazione Comunale, Voghera, who will give all particulars necessary.

San Juan (Puerto Rico).—H.M. Secretary of State for Foreign Affairs has received from H.M. ambassador at Madrid a copy of a Spanish Royal Order which has appeared in the *Gazette* inviting tenders for the construction and working of a telephone system in San Juan de Puerto Rico. A deposit of 800dol. must accompany each tender, which will be considered on August 10. The copy of the Royal Order may be seen on application to the Commercial Department of the Foreign Office between the hours of 11 and 6.

Mexico.—The municipal authorities of the city of Mexico are prepared to receive proposals for the street lighting by incandescent lamps for a period of eight years. Tenders should be sent in by August 31. The Secretary of State for Foreign Affairs has received from the British Consul at Mexico a pamphlet issued by the Municipal Council of the city containing particulars as to the tenders, and this may be seen on application to the Commercial Department of the Foreign Office between the hours of 11 and 6. The plan as laid out accounts for 480 arc lamps of 2,000 c.p. each, and 120 of 1,200 c p., to which are added 150 incandescent lamps.

Southampton.—The Harbour Board invite tenders for the construction and erection of four electric cranes and accessories, and also for alterations to gantry of an existing crane, on the Town Quay, Southampton. Specification, with two general drawings attached, may be obtained on and after 20th inst. from Mr. A. H Skelton, clerk, Town Quay, Southampton, upon payment of £3. 3s., which will not be returned, and further detailed plans may be seen at the office of the electrical engineer, Mr. J. G. W. Aldridge, 9, Victoria-street, Westminster, S.W. Sealed tenders, marked "Tenders for Electric Cranes," should be sent to the clerk by August 31.

Manchester.—The Gas Committee require tenders for the construction of an underground electric lighting sub-station in Piccadilly. The general conditions of contract, bills of quantities, and forms of tender can be obtained on application in writing to Mr. C. Nickson, superintendent, Gas Department, Town Hall, Manchester. A deposit of £1 1s., which will be returned on receipt of a bona fide tender, must accompany each application for a tender form. Sealed tenders, addressed to the Chairman of the Electric Light Sub Committee, and endorsed "Tender for Underground Sub Station," must be delivered at the Gas Office, Town Hall, by 10 a.m. on August 8.

Jassy.—The Mayoralty of the Town of Jassy (Roumania) has given notice that on August 23, 1896, old style (by our reckoning September 4), tenders will be received, for the second time, in the hall of the Municipal Council, for "the installation of a frigorific hall, electric light, and various accessories requisite for new public slaughter-houses. Offers must be in accordance with the specification, the conditions of contract, the special conditions, and the plans deposited in the offices of the director of the slaughter house works, where particulars may be obtained." Tenders are to be enclosed in sealed envelopes, marked "Offre pour l'installation de la Hall Frigorifique," and senders of tenders must abide by articles 68-79 of the Roumanian Public Accounts Act. All tenders and supplementary documents must be in either the Roumanian or French language.

RESULTS OF TENDERS.

Edinburgh.—The Corporation have accepted the estimate of J. Lownie, Gilmore park, for works in connection with the addition and alteration to the central electric lighting station, amounting to £4,397.

Leeds.—In connection with the extension of the electric tramways from Roundhay to Kirkstall, the Tramways Committee have decided to recommend the Council to accept the tender of Laing, Wharton, and Down, London, the amount being £5,740.

Horsham.—The West Sussex County Council have placed the order for the wiring, fitting, and machinery in connection with the installation of the electric light at the asylum for the sum of £5,228 with Messrs. Crittall and Co., Manchester-square, London.

Shoreditch.—The Vestry have received eight tenders for the internal wiring and fitting-up of power station. The highest tender was that of Strode and Co. at £956, and the lowest that of Laing, Wharton, and Down at £428 9s. 6d. The tender of the latter was accepted.

Exeter.—The City Council have accepted the following tenders: Easton, Anderson, and Goolden, Erith, alternators, £1,320; Brush Electrical Engineering Company, three transformers of 30 kilowatt capacity and four of 10 kilowatt, £300; Babcock and Wilcox, water-tube boiler of 300 i.h.p, 140lb. pressure, £630; Fowler-Waring Cable Company, 3 650 yards of cable, £685.

Battersea.—The Electric Lighting Committee have received 35 tenders for the electric lighting of the municipal buildings, and upon the recommendation of the consulting electrical engineer, Mr. Robert Hammond, the following have been accepted by the Vestry, subject to the respective contractors entering into contracts with two sureties for the due and satisfactory execution of the work:

Spurr, Inman, and Co., Limited, boilers and accessories	£668	10	0
Johnson and Phillips engine-house plant	1,030	15	0
Laing, Wharton, and Down, main switchboard and instruments	143	0	0
Chloride Electrical Storage Syndicate, Limited, accumulators	314	0	0
A. H. Wood, Westminster, wiring and fittings	1,042	13	6

BUSINESS NOTES.

Exeter.—The City Council have decided to light Northernhay by electricity.

Sofia (Bulgaria).—It is proposed to construct a system of eight electric tramway lines for the city of Sofia.

St. James's and Pall Mall Electric Light Company.—The share transfer books will be closed to August 5 inclusive.

Calcutta.—Messrs. John King and Co. have applied for a license to supply electricity. Their application is to be considered by the Corporation shortly.

Bristol.—Colonel Marsh, R E., has held a Local Government Board enquiry into the application of the Corporation to borrow £75,000 for electric lighting purposes.

Charing Cross and Strand Electricity Supply Corporation, Limited.—Letters of allotment and regret have been posted. We are informed that the issue was subscribed for nearly four times over.

Acton.—The District Council have decided to ask Mr. Goddard and Mr. Cohen to attend before the Council with reference to Mr. Goddard's letter as to the purchase of Mr. Cohen's electric lighting works.

Direct United States Cable Company.—At the meeting of the Company it was reported that the receipts for the first half of this year were about 13 per cent. above those of the corresponding half-year.

Gloria Electrolytic Incandescent Light Company, Limited.—This Company has been formed, with a capital of £20,000, to acquire and turn to account any patents relating to improvements in lighting by gas.

Digitized by Google

Western and Brazilian Telegraph Company.—The receipts for the week ending July 24, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, amounted to £2,695.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending July 26 amounted to £1,301, as compared with £1,197 in the corresponding week of the previous year, being an increase of £104.

Westminster Electric.—The Board of the Westminster Electric Supply Corporation, Limited, have declared an interim dividend for the half-year ended June 30 at the rate of 6 per cent. per annum, payable on September 1 next.

Bristol Tramways and Carriage Company, Limited.—The traffic returns for the week ending July 24 were £2,445. 6s. 8d., compared with £1,943. 7s. 3d. for the corresponding period of last year, being an increase of £501. 19s. 5d.

Calcium Carbide Company, Limited.—This Company has been formed, with a capital of £500,000, to enter into an agreement with J. C. Bayley, and to carry on business as acetylene gas generators, calcium carbide manufacturers, etc.

Wellington.—The Rural District Council have had several tenders for lighting the town by electricity, and have decided to invite further particulars from the Brush Electric Company with a view to lighting the town by electricity next year.

Stockton.—It is proposed to adopt electricity as the motive power for the tramcars, and negotiations are understood to be pending between the present company and the promoters of a new company. The cars are at present drawn by steam.

Venezuela Telephone and Electrical Appliances Company.—Coupon No. 12 from the 5 per cent. mortgage debenture due on July 31 will be paid from that date at the Consolidated Bank, Limited, and at Messrs. Westendi and Co.'s Bank, Amsterdam.

New Address.—We have received from the Boudreaux Dynamo Brush Company a notice that from August 10 their business style will be "The Dynamo Brush Company," and their address Chiswell House, Finsbury-pavement, London, E.C., instead of at Gresham-street.

Wells (Somerset).—At a special meeting of the Town Council in connection with the proposed installation of electric light, a motion to rescind the former resolutions of the Council in so far as they relate to instructing Dr. Hopkinson and the city surveyor to prepare plans was lost.

Doncaster.—Mr. Charles Fisher, of 19, Wood-street, and late of the National Electric Supply Company, of Preston, is about to put an electric light plant into operation for the supply of the electric light to the neighbourhood. The cost will be the same as gas in the first instance.

City and South London Railway.—The returns for the week ended July 26 were £813, compared with £827 for the corresponding period of last year, being a decrease of £14. The total receipts for the half-year 1896 were £3,488, compared with £3,421 last year, being an increase of £67.

The Civil List Pensions.—A parliamentary paper issued recently gives some particulars about the latest Civil List pensions. Mr. Oliver Heaviside is rewarded for "his work in connection with the theory of electricity," and Mr. Samuel Alfred Varley is given an additional pension for his electrical inventions.

Horsham.—The Visiting Committee of the West Sussex County Council reported at the last meeting that they had agreed with Messrs. Crittall and Co., of 34, North-street, Manchester-square, London, for the wiring, fittings, and machinery in connection with the installation of the electric light at the asylum for the sum of £5,228. 7s.

Waterloo-with-Seaforth.—The Urban District Council have appointed a Parliamentary Committee to deal with the district lighting question. The Chairman said it was rather an important matter, because the company wanted to get on with the building of their generating station, and till the committee was appointed they were unable to proceed.

Hornsey.—At the District Council meeting, Mr. Porrin asked if the Stroud Green-road could not be lighted by electricity by making some arrangement with the Islington Vestry, who were lighting adjoining roads with it. The Chairman: You cannot bring the electric light into Hornsey; you would be encroaching upon the Hornsey Gas Company.

Kidderminster.—In a note last week on the Kidderminster and Stourport Electric Tramways Bill it was inadvertently stated that the Bill was 14 days before the committees instead of four days. The important question was, of course, the terms on which the tramline should be permitted to cross the railway. Mr. Balfour Browne was the leading counsel for the Bill.

The Pacific Cable.—Mr. Audley Coote, the representative of the French Cable Company, states that the project for a main Pacific cable has not been lost sight of by his company, but owing to the approaching Presidential election there has been a delay in the United States in dealing with the Bills to authorise the construction of the line from San Francisco to Honolulu.

Poole.—At the meeting of the Town Council a letter was read from the Bournemouth and District Electric Supply Company, Limited, giving notice that the company intend to apply by memorial to the Board of Trade, in pursuance of the Electric Lighting Acts, for a provisional order authorising the company to supply electrical energy for public and private purposes in the borough.

Wolverhampton.—Owing to the expansion of business, the directors of Messrs. T. Parker, Limited, electrical engineers, Wednesfield-road, have decided to greatly enlarge their works. For this purpose the shareholders and their friends have subscribed the whole of the uncalled-up capital, which now stands at £75,000. It is intended to double the area of the principal workshops, in order to deal more expeditiously with the orders that are reaching the firm.

Baker-street and Waterloo Electric Railway.—Lord Morley's Committee of the House of Lords have passed the Bill sanctioning an extension of the authorised Baker-street and Waterloo Railway so as to place this railway in connection with the London terminus of the Manchester, Sheffield, and Lincolnshire Railway. For this purpose additional share and loan capital is sanctioned to the extent of £100,000. This Bill has now been sanctioned by both Houses.

Bath.—At the meeting of the Urban Sanitary Authority Alderman Sturges moved the adoption of the report of the Electric Lighting Committee with reference to the purchase of the undertaking of the electric light company. He explained that negotiations were now at an end, and all they asked for was the official seal of the authority to the agreement. Mr. Hunt seconded. He said he should like to hear when the Corporation would commence to work the business. The Mayor said that due notice would be given.

Cheltenham.—At a meeting of the Town Council the proposal for the construction of an electric tramway from Leckhampton-road, through the town to Cleeve Hill, was again brought forward. The proposal was made on behalf of Mr. Thomas Nevins, of Nevins Park, Gorey, Ireland. The town clerk was instructed to prepare a provisional agreement as between the Corporation and the promoters. The scheme was discussed some weeks ago, but was then referred back to committee, as the suggested route was considered unsuitable.

Telephone Amalgamation.—At a meeting of the Cardiff Chamber of Commerce last week, the secretary (Mr. W. R. Hawkins) read a letter from the general manager of the National Telephone Company, in reply to the suggestion to amalgamate the two telephone systems. He pointed out that questions of principle as well as detail were involved. He could not explain these by letter, but would make a personal call within a week or so. It was resolved that certain members of the Chamber should meet the manager of the Telephone Company.

Leatherhead.—At the Urban District Council meeting, Dr. Davis, referring to the communication read at the previous meeting respecting a proposed application for a provisional order empowering the introduction of the electric light into the district, asked if it were the intention of the company to obtain an Act of Parliament? The Clerk replied that no company had yet been formed, but notice was given on behalf of a company about to be formed. On the Clerk stating that the Council would receive notice of any application for a provisional order no action was taken.

Bermondsey.—The Vestry have decided to obtain estimates from six of the leading electrical engineers as to the charges each would make for reporting upon the following points: (1) Whether the supply of electricity could be advantageously undertaken by the Vestry, and at what preliminary fees; (2) what would be the best system of supply for the Vestry to adopt, and the best site for a generating station, and the capital required; (3) as to the advisability of combining a dust destructor with the station for the utilisation of heat; (4) generally on the best means of putting the scheme into operation.

Warminster.—At the meeting of the Guardians, Mr. Pullin drew attention to the number of telephone posts and lengths of wire in Upton Scudamore parish, and asked if they were assessable to the poor rate. Mr. Walker replied that the telephone was Government property, and as such could not be rated. They had tried to rate Government property in Trowbridge, but the Government would not submit to be rated, though they were willing to make an annual contribution in lieu of rates. It was decided to ascertain if a similar contribution could not be got from the Government for property in this union.

Personal.—Mr. F. Teague, Coatbridge, has been appointed resident electrical engineer to Paisley Town Council, the Council having some time ago decided to introduce electric lighting. The salary attached to the office is £200. There were about 70 applicants for the situation, of which the committee selected seven.—On the recommendation of the Electric Lighting Committee, Mr. C. H. Yeaman has been appointed assistant electrical engineer to the Islington Vestry at a salary of £160 per annum. Messrs. N. Staneland, H. Knorr, and E. Hoadley have been appointed electricians at £104 per annum.

St. Pancras—In addition to Euston-road and part of Tottenham Court-road, already lit by electricity, the following further main thoroughfares are to be lighted by arc lamps, but the lamps will be fixed beside the kerb, instead of the centre of the road as in the case of the streets mentioned: Chalk Farm-road, Kentish Town-road, Great College-street, Pancras-road, and Gray's-inn-road. It is contemplated to extend still further the public street electric lighting by providing arc lamps from and along Crowndale-road to the Highgate boundary of the parish. The demand of private consumers for the electric light and power continues to increase.

Sunderland.—The half-yearly estimate of the Corporation Committee having charge of the electric light shows that a credit

Digitized by Google

balance of £309 is expected on the half-year's working. A circular has lately been issued calling attention to the reduction of charges from 6d. to 5d. per unit for lighting purposes and from 3½d. to 2¼d. per unit for electric motors and for heating and cooking purposes, these prices being subject to discounts that range from 2½ to 20 per cent. This document states that the electric light at 5d. a unit will be found to be only slightly dearer than gas in Sunderland, light for light, but by economy in use it is possible to bring it down to the cost of gas.

Coventry.—Mr. G. W. Willcocks, M.I.C.E., Local Government Board inspector, has held an enquiry into an application of the City Council to borrow £13,000 for further extension of the electric lighting works. Dealing with the proposed extensions, the town clerk (Mr. Hammond) said the expenditure on buildings would be £1,140. 18s. 9d., and the total capacity of the plant increased to 17,500 lights as compared with 7,500 lights The other items in the increase were £4,410 for machinery; £3,500 for mains and transformers; £559 for house services, meters, etc.; and £200 for a switchboard. The inspector afterwards visited the works. A report will be presented in due course.

Liverpool.—At the meeting of the Finance Committee, the gas inspector submitted a plan for the lighting by electricity of the plateau in front of St. George's Hall. He stated that the first cost would be £250, and the annual expense of maintenance would amount to £135 As, however, the electric light would dispense with the necessity of a number of existing gas lamps, a saving of £97 16s 9d. would thereby be effected, and the actual increased cost would therefore only be £37. 3s. 3d. per annum. Mr. Petrie (deputy chairman of the Electric Lighting Committee) stated that his committee had carefully considered the matter, and were in favour of the recommendations contained in the report.

Cambridge Electric Supply Company, Limited.—The directors announce an interim dividend at the rate of 4 per cent. per annum for the half-year ending June 30, 1896. The revenue returns for the half year show a sale of 92,682 units and receipts of £2,644. 17s. 9d, against 67,223 units and £1,964. 3s. for the corresponding period of last year. The following is the revenue of returns for June quarter, 1896: Number of units sold during quarter, 1896, 27,257, as compared with 21,436 in the corresponding period last year; number of lamps connected on June 30, 1896, 16 099. The revenue from electricity supply was £794. 19s. 11d.; 1895, £625 4s. 4d.; and from meters and other sources £70. 5s. 11d.; 1895, £60. 5s 6d —a total of £865. 5s. 10d, as compared with £685. 9s. 10d. last year.

London Lighting Extensions.—The London County Council have sanctioned applications from the Westminster Electric Supply Corporation to lay mains in Millbank street, Wood-street, Great Peter-street, Greycoat-place, Old Rochester-row, Coburg-row, Greencoat row, Francis-street, Vauxhall Bridge road, Gillingham-street, Belgrave-road, Eccleston Bridge place and street, Artillery row, Hawick-place, and Victoria street; from the Notting Hill Electric Lighting Company of intention to lay mains across Kensington-park-gardens; from the House-to-House Electric Light Supply Company to lay a low-tension main in Old Brompton-road, and high and low tension mains in Collingham-road; and from the Vestry of St. Pancras to lay mains in Crowndale road. The Vestry of Islington also gave notice of intention to lay mains in Pentonville-road, but over these works the Council have no power of approval or disapproval

Hampstead.—At the meeting of the Vestry, the Lighting Committee recommended that a Ferranti automatic device for reducing the loss on transformers be tried in one of the transformer-chambers, at a cost of £50. Mr. Reed chairman of the committee, said it was desired by the committee to save the enormous loss of electricity caused by the use of large transformers. The Ferranti automatic device had been tried in Newcastle, and the Vestry's engineer had recommended that one be tried here. The recommendation was adopted. It was decided to lay mains for the supply of electric current to private consumers in Albion-road and Antrim street. It was also decided to erect a Ferranti switchboard in the extension of the buildings at the station, at a cost of £460. 5s, in lieu of the ordinary switchboard which the Vestry resolved, on May 7 last, to erect at a cost of £150 the difference in cost being £310. 5s.

Bedminster.—A reply has been received to the letter sent by the Parish Council to the Bristol Tramways Company asking for an improvement of the tram service in the neighbourhood of Totterdown. Mr. S White, secretary of the company, said: "Your Council must, of course, appreciate the fact that, as long as we are restricted to horse traction, it would be quite impracticable to extend the tramways in the direction indicated, though, of course, it would be quite possible if a general introduction of electricity were permitted." At the meeting of the Council the Chairman said that he and Mr. A. J. Smith had approached Mr White for the purpose of finding out what the company would be willing to do in the matter. Mr White said that they would be applying for powers in the coming session of Parliament early next year for an electric system in the district. If they got their powers, they would include the Wells-road and the Bath-road.

Hull.—The Finance Committee at their last meeting renewed the discussion on the matter of the application of the Electric Lighting Committee to borrow £42,000 for electric lighting extension. The Treasurer said that, according to figures furnished him by the electrical engineer, and by calculations he had made himself with reference to interest and sinking fund, the total probable cost of the old station next year would be about £5,299, If the new station were in working order for the whole year, the cost, based on the same calculations, would be about £4,489. The total estimated expenditure was £9,786, and the total estimated receipts £9,800 leaving a balance of £14 for the year. In that calculation he had charged the whole year's interest and sinking fund, when in all probability it would not have to be paid because the works were not in hand nor likely to be. After some further discussion, the matter was adjourned to a special meeting.

Battersea (London).—At the meeting of the Vestry, Mr. Sellicks, on behalf of the Special Electric Lighting Committee, moved the adoption of certain important recommendations. These included the electrical lighting of the municipal buildings and town hall and the central library. The committee having conferred with the engineer, recommended that contracts be entered into with Messrs. Spurr, Inman and Co., Messrs. Johnson and Phillips, Messrs. Laing, Wharton, and Down, Mr A. H. Wood, and other firms, for the supply of boilers, accessories, switchboards, wiring, and fittings, etc. The work of building cutting away for wiring, making good, etc., will be carried out by men in the direct employ of the Vestry The tenders amounted to £3,198. 18s. 6d. Buildings are estimated to cost £600; cutting away and making good, etc, £200; and the engineer's fees. £200—total, £4,198. 18s 6d. It was asked that the matter be referred back to the committee, with power to carry the scheme into effect, and that application be made to the London County Council for a loan of £4,200 necessary to defray the cost of the work. The report and recommendations of the committee were adopted without discussion.

Southampton.—The Works Committee recommended at the meeting of the Town Council that they be empowered to retain the services of an expert, at a fee of not exceeding 50 guineas, to advise the Corporation on the following points: the probable life of the permanent tramway; the suitability of the permanent way for electric traction; the present value of the permanent way; estimated repairs per annum; the desirability of using overhead or underground wires for electric traction. Mr. Lemon moved the adoption of the report, explaining that they proposed to work the cars by electric traction; but if they thought this undesirable they intended to call in an expert for advice, and therefore the question of rolling stock had been left out of consideration. Alderman Button seconded the adoption of the report. Mr Le Feuvre strongly objected to the use of overhead wires in electric traction. If they were going to make £50,000 a year he would not consent to their beautiful town being spoilt by overhead wires, and he suggested that the borough engineer should not be asked to report on the desirability of overhead wires, as it would merely be a waste of energy. The report was adopted.

Edinburgh.—The directors of the music hall have just spent over £2,000 upon its redecoration and the introduction into it of the electric light. The scheme has been carried out under the direction of Dr. Rowand Anderson by Messrs. Moxon and Carfrae. A long discussion took place at the meeting of the Town Council on the report of the Electric Lighting Committee, adhering to a former recommendation for the establishment of a renewal fund. It was eventually decided "that the question as to the disposal of the moneys received from the electric light undertaking raised by the motion of Councillor Mackenzie be remitted to a joint conference of the Electric Lighting, Treasurer's, and Law Committees, with power to take the opinion of counsel." On the recommendation of the Electric Lighting Committee, it was agreed to accept the estimate of Mr. John Lownie, Gilmore Park, for works in connection with additions and alterations to the central electric lighting station amounting to £4,397. It was unanimously resolved to accept an offer by Mr. M'Ewan, M.P., to erect an ornamental electric lamp pillar in the centre of the vacant space on the east side of the M'Ewan Hall. A remit was made to the Cleaning and Lighting Committee, in preparing the estimates for the current year, "to take into consideration the requirements of an extended area as at November 1 next, inclusive of Portobello, with the view of improving the public lighting thereof"

Fulham.—At the meeting of the Vestry the Electric Light and Dust Committee reported that they had received a letter from Mr. S Marl, of 4, Fenchurch-avenue, E.C., stating that he was instructed by the County of London and Brush Provincial Electric Lighting Company, Limited of Moorgate-court, to inform them that application was intended to be made on or before December 21 next by that company by memorial to the Board of Trade, in pursuance of the Electric Lighting Acts, 1882 and 1888, for a provisional order to be confirmed in Parliament in the ensuing session whereby it is proposed to authorise the said company to apply electrical energy for public or private purposes within the area of the jurisdiction of the local authority as defined by the above Acts for the district of the parish of Fulham. A letter was also read from Mr. Charles W. Sax, of 53, Charterhouse-street, West Smithfield, asking the favour that the clerk would inform the Vestry that he intended to apply to Parliament next session for a provisional order to supply Fulham with electrical energy. On the motion of Mr. Terry, it was resolved that the Vestry oppose the granting of the provisional orders. The report of Mr. F. H. Medhurst as to the installation of the electric light in the parish and the erection of a dust destructor in connection therewith was considered, and the committee agreed to the appointment of a deputation to visit Oldham, Leeds, Warrington, Bedford, Brighton, and Portsmouth. When, however, the report was brought up at the meeting of the Vestry the chairman ruled it out of order.

Callender's Cable and Construction Company, Limited.—This Company has been formed to purchase as a going concern the business and works founded by Messrs. Callender and Sons, and carried on for the last 14 years by Callender's Bitumen Telegraph and Waterproof Company, Limited, at Erith, London, and elsewhere, together with the freehold factory, goodwill, stock-in-trade, book debts, bills, cash balance at the bank, and other

Digitized by Google

assets, and subject to all the liabilities of the business. It is certified that the profits for the five years ending December 31, 1895, after providing for all working charges, repairs, expenses of management, and appropriating £11,500 for depreciation during that period, but without charging directors' fees or interest on debentures and loans, amounted to £68,573. 1s. 9d., being an average of £13,714 12s. 4d. per annum. The profits for 1895 forming part of the above figures after appropriating £3,000 for depreciation for that year, amounted to £16,279. 2s. 10d. The capital is £100,000 in shares of £5, the whole of which has been taken by Callender's Bitumen Telegraph and Waterproof Company, Limited, and 4½ per cent. first mortgage debenture stock for £90,000, of which £40,000 will be allotted in exchange for the debentures of that amount in Callender's Bitumen Telegraph and Waterproof Company at par, and the balance—viz., £50,000—is now offered to the public at 103. The debenture stock will be secured by a first mortgage on the freehold premises and plant, and a floating first charge on the remaining assets of the Company, and will be redeemable at the Company's option after June 30 1916, at 110 per cent.

Appointments Vacant.—The Corporation of Sunderland require the services of an electrical engineer to act as resident engineer at their electric lighting station, and to design and superintend any extensions of their station, plant, and mains. Any extensions of the station buildings will be designed and carried out after consultation with him by the borough or other engineer. A schedule of duties can be obtained from Mr. Fras. M. Bowey, town clerk, Town Hall, Sunderland. It is essential that candidates should have been properly trained both as mechanical and electrical engineers, have a full knowledge of both the three-wire continuous-current and the high-tension alternating-current system, and have had central-station experience. The candidate selected will be expected to enter upon his duties by September 1. Canvassing is prohibited. The engagement will be for four years certain from the date of the engineer entering upon his duties, subject to the option of the Corporation to determine it by three months' previous notice in writing, expiring at the end of the first year. The salary will be for the first year £300, second year £350, third and fourth years £400 per annum. Subject as above the engagement to continue after the fourth year at the salary of £400 per annum, with the right of either party to determine it at the expiration of three months' previous notice in writing. Applications, stating age, station experience, and accompanied by original testimonials, to be addressed to the town clerk, endorsed "Application for Electrical Engineer," to be delivered by August 4.—The Hammersmith Vestry have decided to invite applications for the office of resident engineer, at a commencing salary of £200, during the construction of the electric lighting works, to be increased to £250 when the installation is completed and in working order. The applications will be considered at the first meeting after the recess.

Catalogues.—We have received an illustrated catalogue from Mr. F. C. Allsop, manufacturing electrician, of 97 Queen Victoria-street, E.C., from which we gather that Mr. Allsop has in stock a large assortment of every article that an electrician may require. The catalogue is arranged in a convenient form, and the prices can be ascertained at a glance.—We have already briefly acknowledged receipt of a catalogue from Messrs. Rosling and Appleby, mechanical and electrical engineers and brassfounders, of Trafalgar Works, Bradford. This catalogue gives full particulars and prices of dynamos for running either arc or incandescent lamps, or for transmission of power; also of motors for cranes, hoists, pumping, hauling, coal-cutting, and tramway plants, etc.—Mr. A. B. Pescatore, of 5, Cross-street, Manchester, sends us a very interesting price-list of the Tudor accumulators, of which he is the sole manufacturer in the United Kingdom. He calls attention to his special type of plates for renewals, of which he has already supplied a large number, and he informs us that owing to an improvement in the manufacture of Tudor plates, he has been enabled to considerably reduce the prices; this is especially the case for stationary cells discharging at three to ten hours' rates, where the reduction in price is fully 15 per cent. The rates of maintenance are reduced in the same proportion as the prices—*i.e.*, they remain at 3½ to 6 per cent. off list price—and at the same time the guarantee given with all batteries is extended to two years. The S type of cell given in the catalogue has been specially designed for isolated installations, where smaller batteries than the ordinary stationary types S.L. and S.H. are required. The new types of portable cells have now been perfected in all their details.—We have received two catalogues from C. W. Treacher and Co., of 165, Queen Victoria-street, E.C., one of which contains useful diagrams, which will enable anyone to see how a house should be wired; and although we deprecate the growing practice of allowing inexperienced men to erect electric light installations, we think these hints will be useful as a guide to workmen. Mr. Treacher has gone fully into the telephone question, and his catalogue of instruments, wires, and accessories is most full and complete. Here again the diagrams of connections will be exceedingly useful. He has also listed a speciality for lighting an ordinary gas burner by electricity. An induction coil is used, and a spark made to pass between two points near where the gas jet is issuing.

Islington (London).—At a meeting of the Vestry a report has been received from the Electric Lighting Committee, stating that with a view to give effect to the resolution of the Vestry of May 8, 1896, it had instructed the architect, Mr. A. H. Tiltman, F.R.I.B.A., to prepare plans for the extension of the electric lighting station so as to provide accommodation for the required additional plant; submitting such plans for the inspection of the Vestry; and recommending that such plans be approved and adopted. This was agreed to. Another report was received from this committee, stating that as the agreement, dated October 7, 1893, whereby the services of Mr. Gay as electric lighting engineer where secured to the Vestry for a period of three years, at an annual salary of £400, will expire in October next it has considered the question of his reappointment with a view not only to the proper control of the existing works and station, but to the supervision of such extensions or alterations thereto as may be required from time to time; and that having regard to the very satisfactory manner in which the engineer has discharged the onerous duties which have devolved upon him during his service with the Vestry, it recommended that he be appointed electric lighting engineer during the pleasure of the Vestry, at a salary of £500 per annum, as from January 1 last, with further annual increments of £50 as from January 1, 1897, until a maximum salary of £600 is reached. The motion was agreed to. The committee also reported that, pursuant to Vestry reference of July 3, 1896, of an intended application by the County of London and Brush Provincial Electric Lighting Company, Limited, to the Board of Trade for a provisional order authorising the company to supply electrical energy within the Vestry's area; and that in connection therewith it has interviewed the company's chief engineer and solicitor, who state that the object of the proposed application is to enable the company to lay mains from Wharf road, along Frome-street and Arlington street to the New North-road, so as to form a connecting link with the parishes of Shoreditch and Hackney and also along the City road from St. Matthew's Church to the Angel Tavern, so as to form a connection with the company's mains in the parish of Clerkenwell; and recommending that the consent of the Vestry to the proposal of the company be not given, and that any application of the company to the Board of Trade for a provisional order be opposed. This was again agreed to. A report was received from the General Purposes Committee, stating that it has considered a reference from the Public Health Committee requesting that arrangements be made for establishing telephonic communication between the Vestry Hall and the shelter-house near the Vestry's disinfecting station in the Seven Sisters'-road; that in connection with the reference, it has appointed a sub-committee to consider the question; and recommending that the offer of the National Telephone Company to respectively connect the Liverpool-road depôt and the disinfecting station with the Vestry Hall by telephone, at annual rentals of £6 and £19 respectively on a three years' agreement, be accepted. The Vestry have decided to extend the mains in Goswell-road and Graham-street, City-road, at an estimated cost of £700.

The Brockie-Pell Arc Lamp, Limited.—This Company has been formed to acquire Messrs. Brockie and Pell's inventions for the construction of electric arc lamps as embodied in various patents and patent rights and all future improvements on such patents. The Company will acquire the goodwill attaching to such patents, and the business connected therewith and they will work and develop their business in connection with the several patents and patent rights and otherwise. The Company comes before the public, not as a concern to establish a connection, but with a valuable business already built up, the profits from which it is believed will yield a handsome dividend to the shareholders. The business of the Company will consist of and their revenue be derived from the manufacture and sale of the lamps and accessories, the granting of licenses, the supply of installations and plant, and the general business of electrical engineers. The manufacture and sale of the lamps and incidental business have hitherto been carried on by a firm of electrical engineers under arrangement with the patentees, who have received a royalty on the sales. The termination of that arrangement affords the directors the opportunity to make the present issue, which will provide the capital necessary to enable them to manufacture the lamps in such quantities as will supply the increasing demand and to carry on and extend the business. The sale of the lamps is an increasing one. The year 1895 showed a continued increase, whilst for the first quarter of 1896 there was an increase of more than 27 per cent. over the corresponding quarter of 1895. It is also expected that a considerable addition of profit will accrue from the active working of the European, foreign, and Colonial patents, which up to the present time have been worked to a very limited extent. The directors are of opinion that the sales of lamps alone should yield sufficient net profit to enable the Company to pay a dividend of 7½ per cent., and also that as the Company proposes to themselves manufacture the lamps, the net income derived from this source alone should suffice to raise the dividend to at least 12½ per cent., and further that the profit on the manufacture and supply of accessories, the supply of installations and plant, the profit on repairs and on incidental business, should yield a further income which should provide a total dividend of at least 17½ per cent per annum. These figures leave out of count the profits to be obtained by the working of European, foreign, and Colonial patents. Over 10,000 of the lamps have already been sold. It is claimed for them that they give a steady, white light, without the flickering or the variation common to other arc lamps; that they are very economical in carbon consumption, and as they burn 40 hours without attention or recarboning, the cost of maintenance is considerably reduced; that they work satisfactorily on either constant-current or constant-potential circuits, and with continuous, alternating, or rectified currents; and that they have very simple mechanism, consequently their working is easily understood and they keep in perfect adjustment and good order for very long periods. Sir David Salomons, Bart., and Dr. Hopkinson have reported very favourably on the lamps. The purchase-money has been fixed by the vendors at £60,000, payable £30,000 in cash, £25,000 in fully-

Digitized by Google

paid shares, and £5,000 in cash or shares at the option of the Company. The capital is £80,000 in £1 shares.

PROVISIONAL PATENTS, 1896.

JULY 20.

16019. Improvements in regulating switches. Rookes Evelyn Bell Crompton and Edmund Arthur Norman Pochin, 55, Chancery-lane, London.

16057. Improvements in electrolytic apparatus. Carl Kellner, 46, Lincoln's-inn-fields, London.

JULY 21.

16082. Improvements for fittings in incandescent street lamps and the like. John Westwood Lee and John Hall Perrins, Midland Works, Bracebridge-street, Birmingham.

16091. Improvement in electric batteries. Adolphe Stevens and François Puttaert, 8, Rue des Princes, Brussels.

16152. Apparatus for controlling electric currents. Joachim Estrade, 18, Buckingham-street, Strand, London.

16168. Improvements in insulators. Benjamin Du Bois Smock, 40, Chancery-lane, London. (Complete specification.)

JULY 22.

16231. Improvements in electric motors and dynamos. George Seymour and Samuel Allen Letts, 60, Cleveland-gardens, Barnes, London.

16256. Improvements in electric furnaces. Louis Michel Bullier, 53, Chancery-lane, London. (Date applied for under Patents, etc , Act, 1883, Sec. 103, December 28, 1895, being date of application in France.)

16257. Improvements in electric furnaces. Louis Michel Bullier, 53, Chancery-lane, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, January 27, 1896, being date of application in France.)

16268. Improvements in electric batteries. Walter Rowbotham, 45, Southampton-buildings, Chancery-lane, London.

16270. Improvements in secondary electric batteries. Marie Oscar Armand Garreau, 45, Southampton-buildings, Chancery-lane, London.

JULY 23.

16226. Improvements in apparatus for obtaining electric discharges. Frederick William Golby, 36 Chancery-lane, London. (Alexander Vosmaer, Holland.)

16342. Improvements in or relating to prepayment mechanism for electrical or other meters. Charles Orme Bastian and Herbert Cecil Hodges, 31, Southampton-buildings, Chancery-lane, London.

16358. Improvements in or in connection with electric railways or tramways. Henry Joseph Gill, 6, Lord-street, Liverpool.

JULY 24.

16373. Improvements in the distribution of electricity, and in junction boxes for use therein. William Illingworth and Thomas Smith, 18, St. Ann's street, Manchester.

16404. Improvements in and relating to electrical signalling apparatus or bells. Samuel Jevons and William Collins, 77, Colmore-row, Birmingham.

16407. Improved means applicable for use as an "engine-room telegraph" and for other signalling purposes. Charles Ashmore Baker, 191, Fleet-street, London.

16418. Improvements in the method of and means for automatically regulating arc lamps and other electrical apparatus. Willem de Graaff, 23, Coleman-street, London. (Complete specification.)

16421. Regulator for dynamo machines. Anton Heusch and Paul Brandt, 70, Chancery-lane, London. (Complete specification.)

16435. Improvements in filaments of electric incandescent lamps. Frank Eustace Wilkins Bowen, 6, Bream's-buildings, Chancery-lane, London.

16445. Apparatus for controlling electrically-actuated railway point apparatus. Siemens Bros. and Co., Limited, 28, Southampton-buildings, Chancery-lane, London. (Siemens and Halske, Germany.)

16457. Improvements in solenoid cores for voltmeters. Paul Brandt and Anton Heusch, 31, Southampton-buildings, Chancery-lane, London. (Complete specification.)

JULY 25.

16475. Improvements in electric arc lamps. Edward Jones, Albert Edward Jones, and George Kynoch and Co., Limited, 18, Southampton-buildings, Chancery-lane, London.

16502. Improvements in and connected with electric clocks. William Whitehead, 4, Corporation-street, Manchester.

16534. Improvements in filaments for use in electric glow lamps. Frédéric de Mare, 45, Southampton-buildings, Chancery-lane, London.

16539. Improvements in the manufacture of cables for telephonic, telegraphic, electric lighting, and other electrical purposes. Phillip Ormiston and Salomon Berditschewsky Apostoloff, 53, Chancery-lane, London.

16514. Improvements in electrical switches. William James Davy, 40, Chancery-lane, London.

16516. Improvements in accumulator batteries. John Vaughan-Sherrin and Henrietta Helena Sherrin, 77, Chancery-lane, London.

16533. Improvements in filaments for electric glow lamps and in methods of manufacture of the same. Frédéric de Mare, 45, Southampton-buildings, Chancery lane, London, (Date applied for under Patents, etc., Act, 1883, Sec. 103, January 28, 1896, being date of application in France)

SPECIFICATIONS PUBLISHED.

1895.

12613. Electric railways or transport. Lorrain. (Esmond.)

12615. Electric railways or electric transport. Lorrain. (Esmond.)

12616. Electric railways or electric transport. Lorrain. (Esmond.)

12697. Automatic electric fire-alarm and indicator of heavy air in a room or other enclosed space. Harsen and Frimand.

15174. Single-phase and multiphase alternate-current motors. Atkinson.

15288. Electric clocks. Lake. (Société Anonyme La Précision.)

16247. Electric cables or conductors. Edmunds.

16248. Electric transformers and dynamo armatures. Edmunds.

17123. Linked suspensions for electroliers, electric light pendants, and the like. Hirst.

18483. Electric glow lamps. Davis.

19628. Electric burglar alarms and the like. Boult. (Damseaux.)

1896.

7896. Electrical haircutters and singers. Bell and Sloss.

8948. Electrical signalling apparatus. Lake. (Painter.)

9817. Shade for use in connection with electric incandescent lamps and the like. Bach, Lewis, and Saunders.

10096. Arc electric lamps. Mackin.

11162. Electric time alarm apparatus. Golby. (Winter.)

11417. Means for electrically connecting the rails or sections of electric railways. Brown and Huntress.

NOTES.

Obituary.—The death is announced of Prof. Adolfo Bartoli, of the University of Pavia.

Crystal Palace.—The award of certificates at the Crystal Palace School of Practical Engineering takes place to-day (Friday), Major E. Raban presiding.

Lisbon in Darkness.—A strike of nearly all the workmen and lamplighters of the Lisbon gasworks left that city in darkness on Saturday and Sunday last. It is stated that people fell back on Chinese lanterns and candles.

The Civil Engineers.—The Institution of Civil Engineers have obtained an injunction to restrain the Institute of Civil and Mining Engineers, Limited, being registered under that title or under any similar name or title calculated to deceive the public into believing the new company to be the institution of the plaintiffs.

An Electric Boat.—According to a report from Brighton, a new Mayne electric motor rudder boat belonging to Earl de la Warr has made a trial trip to sea with fairly good results. The boat is 30ft. in length, with a beam of 6ft., and is fitted with the electric motor close to the keel. The motor is driven by accumulator cells, which fit neatly into the waist of the boat.

The Canadian Tariff.—The Judicial Committee of the Privy Council, on the appeal of the Toronto Street Railway Company from the Canadian Courts, have decided that steel tramway rails should pass as railway rails if above the weight specified in the tariff. It must be remembered that on the American continent a railway is a "railroad," and a tramway in many cases a "railway." Hence difficulties in construing the tariff clauses.

Petroleum Committee.—The report of the Select Committee on Petroleum, together with the proceedings, has been issued as a parliamentary paper. The report is as follows: "Your committee are of opinion that at this late period of the session it will not be in their power to conclude their investigation; they have, therefore, agreed to report the evidence already taken to the House, and to recommend that a committee on the same subject should be appointed early in the next session of Parliament."

Australian Telegraphs.—An unprecedented event in the history of Australian telegraphy occurred on June 22, when telegraphic communication by every route from Melbourne to Sydney was completely interrupted through a heavy snowstorm which occurred over a wide area beyond Yass during the early hours of the morning, and brought all the lines down. The curious thing about the interruptions of these Trans-Australian lines is that they never seem to get into the official list issued from Berne every month.

Motorcarts.—Mr. G. T. Holloway has called attention to difficulties which may occur under the present law (even as amended by the new Act) with oil motorcarts if oils flashing below 73deg. F. are used. This, of course, covers all benzine motors. It may be said that the Secretary of State is empowered by the Act to make such regulations as he sees fit, to permit the use of such low-flash oils, but whether, as is suggested, he will be able or willing to overrule the regulations of the local authorities as to storage is at least doubtful. These, of course, vary from place to place.

Lightning.—During a thunderstorm on July 29, the Italian coast defence armour-clad vessel "Roma" was struck by lightning and set on fire. As the flames seemed likely to reach the powder magazine, and also threatened to attack the coast defence armour-clad vessel "Palestro," which was filled with explosives, it was found necessary to sink the "Roma" by means of two torpedoes. One would have thought that an armour-clad vessel with presumably iron masts going down to the kelson, and almost certainly iron standing rigging, was about as safe a thing in a thunderstorm as could well be.

Electric Fans. — Our contemporary the *Engineer* suggests doing away with windsails on board steamers entirely, and substituting electric fans. In warships the fan ought to be placed where room can be found for it low down in the ship—far below the water-line. An electrically-driven horizontal fan, with its motor, can be got into the thickness of a deck with its beams, if needs be. This would clearly be better than depending on a flimsy construction, which would certainly be greatly damaged, if not entirely shot away in action. If clear decks are wanted, the windsail is about as inconvenient as it is ugly, and that is saying a great deal.

Research Scholarships.—Her Majesty's Commissioners for the Exhibition of 1851 have made the following appointments to Science Research Scholarships for the year 1896: William Craig Henderson, M.A., B.Sc.. Alexander Ogg, M.A., B.Sc., Thomas Slater Price, B.Sc., Emily Comber Fortey, B.Sc., Harry Medforth Dawson, B.Sc., Henry Edward Annett, M.B., Joseph Ernest Petavel, John Leathart Heinke, B.Sc., John Armstrong Smythe, B.Sc., George Blackford Bryan, B.Sc., Spencer William Richardson, B.Sc., David Williams, John Henry, M.A., B.Eng., A. M. Scott, Douglas McIntosh, B.Sc., John Angus Erskine, M.A. The scholars are to devote themselves exclusively to study and research in some branch of science the extension of which is important to the industries of the country.

The Light Railways Bill.—In the House of Commons on Monday Mr. Elliott Lees asked the President of the Board of Trade whether his attention had been called to the danger of injury being done to existing electric lighting undertakings if electric railways should be constructed under the Light Railways Bill, unless the regulations now prescribed by the Board of Trade with regard to electric traction were amended so as to include precautions to prevent the currents of existing electric lighting undertakings being affected by the currents of electric railways; and whether he was prepared to amend these regulations. Mr. Ritchie replied that it would be the duty of the Board of Trade to see that there was inserted in the order authorising a light railway proposed to be worked electrically, such provisions to secure public safety and the interests of electric lighting or other undertakings as they might deem advisable. If it was necessary to amend the existing regulations, they could be amended in the order.

The Brand New System of Electric Traction.—The paper on the above subject is found elsewhere in this issue. It was read before the Tramways Institute, and consists mainly of a reprint from a patent specification. We have left the patent claims out as being rather redundant after the paper. We only trust that the bad science and grammar in the paper have not passed the fatherly supervision of the Patent Office staff. The assertion that "the earth is at all times a great induction magnet constantly tending to rob a naked conductor of the electric fluid," is too new to pass without comment. After reading this, we cannot wonder that the paper shows a general want of knowledge of electrical subjects. Thus the system, in spite of all the claims, is no

Digitized by Google

better in respect to electrolysis effects than those now in daily practice. The complications involved in the equipment of the conduit and the mechanical plungers are such as to cause an excessive first cost. Besides this, the system would be highly dangerous to the general traffic, we think even more so than the "death-dealing trolley."

Street-Lighting.—The method of placing arc lamps in the centre of a wide street gives a good distribution of light, and at the same time a pleasing effect. This necessitates a refuge round the base of the lamp, which is also a great convenience for foot passengers. A new aspect of the case has, however, arisen at Islington, where, to save expense, the lamp on one of these refuges has been switched out at a certain hour each night. No less than three hansom cabs have collided with the obstruction caused in Upper-street. The first case was tried at the Clerkenwell County Court, and the judge held that the Vestry had a perfect right to extinguish the lamp. The jury, taking, perhaps, the common-sense view of the matter, gave a verdict for the cabby, which the judge did not allow. As the case is under appeal, further comment would be out of place at present. From the recommendation of the Electric Lighting Committee to the Vestry, which comes up for consideration to-day, we see that the Vestry is advised to stick to its guns. We would suggest that a few incandescent lamps grouped round the lamp column would be the best way to check the series of accidents.

Mining Engineers.—The annual general meeting of the members of the North of England Institute of Mining and Mechanical Engineers was held in the Wood Memorial Hall, Newcastle-on-Tyne, on Saturday. The president, Mr. Thomas Douglas, in his address, said: as to the questions which were engaging their attention they had still a great deal to learn regarding coal dust in mines. There were still differences of opinion amongst them regarding the matter, and it amounted to this, that they would have to have much more reliable information regarding the mode in which men met their death than they had had. Then there was electricity that had engaged their attention. As to its introduction into mines, the fear of danger arising from the emitting of sparks was for the moment a reasonable one. He did not believe, however, for a moment that their scientific knowledge would not find a remedy for this, and as he was persuaded that electricity was the coming power he was quite sure that its introduction with safety into the operations of mining would be an important and beneficial change. The financial report showed a surplus of income over expenditure, and there has been an increase of membership.

The Institution of Mechanical Engineers.—The summer meeting of the Mechanical Engineers at Belfast last week was a most successful one. The papers read were interesting, and the several functions conduced to the mutual introduction of the members. The annual dinner was given at the Grand Central Hotel. In answering to the toast of "The Institution of Mechanical Engineers," the President (Mr. E. Windsor Richards) said he was very proud of the position to which he had been elected. The institute was, he was glad to say, in a very flourishing condition. There were a great number of engineers seeking admission, but they were very careful in electing anyone, as they must fulfil the obligations which the council exacted. He might mention, for the benefit of the members, that, owing to strike and other difficulties, their house in St. James's Park had been delayed in building, but they hoped in the course of a year or so to have it open. The Belfast meeting had been one of the most successful and pleasant ever held by the institution, and if it were possible, he would use stronger words than he had already used in thanking the people of Belfast for their warm reception.

Trinidade.—It is announced in the Lisbon newspapers that the British Government has finally recognised the sovereignty of Brazil over the islet of Trinidade. (This spelling is the preferable one for several reasons.) If the news is correct, it is to be regretted. The Brazilian Republic, which has a great deal more territory on hand than it can manage, had no better claim to the islet than anybody else. It has been taken possession of at different times by various countries and subsequently abandoned as absolutely useless, which, indeed, it is except for the purpose of a submarine cable station. It is to the interest, not only of Great Britain, but to the whole of Europe, that its telegraphic communication with the greater part of South America should be as little as possible at the mercy of states that are frequently at variance with each other, and particularly liable to revolutions and internal disturbance. Trinidade would have served admirably to bridge the long gap between Ascension and the Plate, and even if there is no immediate prospect of a direct cable being laid, the abandonment of the islet to Brazil is one of those surrenders which are incomprehensible to outsiders. Some day the security of our commerce round the Horn and our colony of the Falkland Islands may prove to be appreciably lessened by it.

Calcutta Corporation and Cables.—Our contemporary *Indian Engineering* in a recent issue criticises editorially in no feeble manner a report by a professor on the question of what electric cables should be used for arc lighting in Calcutta. We wish we could have a copy of the report of the professor to read with the remarks of his critic to give us an insight into the points referred to. The main points of difference between the professor and editor appear to be that of the use of overhead wires, the wording of the report, and the methods of testing. The professor recommends that "every main shall be tested for insulation, the testing pressure being 200 volts" (the working pressure may rise to about 1,000 volts). From the above the editor concludes that the professor "is evidently unaware of the facts that firstly the current rating of underground cables depends either upon tension losses or upon the temperature of the soil through which they are laid; and is practically independent of their insulation; and secondly the works test to which such cables are put is usually 1·5 times their working tension, the B.T. test pressure when laid 100 volts." After reading the above we had to give up the idea of adjudication in the matter of either grammatical construction or technical knowledge.

A Ring Lamp.—In *L'Elettricità* there has been figured and described a rather curious and, so far as the writer knows, novel shape of incandescent lamp which has been brought out by the Ediswan Company. Instead of the ordinary more or less pear-shaped bulb, the lamp takes the form of a long glass tube bent round into a circle. There are four filaments, each one covering a quadrant of the circle, and these are kept in the centre of the tube by four loops. So far as can be judged by the illustration, the lamp requires five connections to feed it—*i.e.*, two positive and three negative, or, conversely, since the ends of the glass tube meeting make what would be the fourth connection a double one. If, however, the voltage were high enough, there appears nothing to prevent these last two connections being alone used and the current sent all round the ring, instead of along a quarter of the circle only. On these points the description in our contemporary gives no information. It, however, states that this form of lamp will be particularly

Digitized by Google

adapted for theatrical use, and to be worn on the heads of dancers or fairies. Since it would supply a means of representing the aureola about the heads of saints, it is further considered that the lamp would be effective in religious ceremonies and processions.

Alternate-Current Motors.—Prof. Dugald Jackson has recently read a paper on the above subject before the North-Western Electrical Association in America. He gives the results of tests of a series of alternate-current motors, both for multiphase and single-phase work, and states that four out of the six motors tested affected the incandescent service disastrously. They show, in the professor's opinion, the absurdity of attempting with them a combined light and power service on the same circuit. The conclusions of the matter as it now stands, in the professor's estimation, are as follows. If you have a 500-volt continuous-current power service, stick to it. If you can develop a large power service within a radius of two miles from the station, put in a 500-volt continuous-service outfit. If you can develop a small power service only, which cannot afford a duplication of apparatus, or your distances are excessive, then arrange to use alternate-current motors. In this case arrange to operate all the lamps on one phase to avoid, as far as possible, difficulty of regulation, and use such a generator and system of lines as will enable the use of motors. Motors intended for use should have a high power factor, and should start without taking an excessive current from the lines. With motors, recording wattmeters must be used. This summation of leading principles by the professors is based on the assumption that uniformity of pressure at the lamps is valued by all central-station men. We shall reproduce the tests shortly, and in the meanwhile leave our readers to wonder what alteration would be made in the above conclusions if the two satisfactory motors out of the six were to be employed.

Armature Torque.—Mr. T. Wolcott, in the *American Electrician*, considers the question, Is it the attraction between the field magnets and the iron core of a motor that gives rise to the useful torque, or is it the attraction between the field and the armature conductors, or between the field and the current in the armature conductors? The author proceeds to treat the question generally, but, unfortunately, he does not take practical examples. Hence his conclusion can only be approximate, as, for instance, any comparison between the old Siemens H armature and the modern toothed core armature. The final paragraph reads as follows: "A part of the torque even in a smooth-cored armature is due to ferric attraction, but this part is probably very small, and experience proves that nearly all the strain is on the conductors direct, for there is a strong tendency of the conductors to slide upon the core. In conclusion, it may be said that there are two distinct actions tending to produce torque. First, the direct action of a magnetic field on a conductor carrying a current tending to move it across the lines of magnetic induction, but not to attract or repel it. Second, the magnetic attraction and repulsion between the field poles and parts of the armature core, which attractions and repulsions, although due to the currents in the armature conductors, do not necessarily involve any mechanical strain on the conductors, though under certain circumstances they may do so. Both of these actions may and do exist in the same motor, but in motors having smooth armature cores the first is the principal one, the second being of no practical importance, while in motors having toothed armature cores the reverse is the case—that is, the direct attraction of the teeth by the field poles is the chief source of torque."

"The Scientific American."—This journal celebrated last week its fiftieth anniversary, and its issue for July 25 is enlarged to 64 pages to commemorate the event. On the first page of this number there are reproduced on a smaller scale the fac-simile of pages in the first issue, dated 1845. The following note on one page shows the state of telegraph work at that date: "Morse telegraph—This wonder of the age, which has for several months past been in operation between Washington and Baltimore, appears likely to come into general use through the length and breadth of our land. Arrangements are already made for extending the lines to Philadelphia, New York, Albany, Buffalo, Springfield, Boston, and various other cities and sections. Hon. Amos Kendall, ex-Postmaster-General, has taken the management of the invention—whether as proprietor or agent we are not informed—while the inventor is on a tour to Russia. We shall take an early opportunity to give our readers a full and minute description of this invention, with explanations and illustrations of its principles; but in consequence of the press and variety of matter which presses on this our first number, we are constrained to defer it. We will add the remark, however, that it is contemplated by the merchants of our Western States to communicate their orders for goods, etc., by means of the telegraph, instead of abiding the slow and tedious progress of railroad cars." Smith's electromagnetic machine for medical purposes is also described and illustrated, and a note at the end of the description states that "these machines, finished in elegant style, will be furnished at the low price of 7dol. 50 cents at this office." The rest of the paper is devoted to a series of reviews of progress made during the last 50 years in the various arts and sciences.

Hot Bearings.—The following, which is from our New York contemporary, the *Electrical World*, may be of interest as embodying American practice and views of one of the causes of temporary breakdowns: "In small central stations, particularly where one or more jack shafts are employed, overheating of the bearings become a serious matter, often resulting in the necessity of shutting down the portion of the plant directly affected. Most engineers prefer to ruin their machinery, if by so doing a shut down can be avoided. The common practice in cases where the bearings become hot is to freely apply water, and, if possible, ice, and at the same time sufficiently lubricate to reduce the friction The use of water on dynamo bearings is, however, a dangerous proceeding, owing to the liability of injuring the armatnre. Ice, while more easily handled, is not always obtainable, and is likely to produce the same harmful results. The continuous use of water on bearings is never desirable, although sometimes necessary, as in the case of marine engines. It is owing, however, to occasional necessity that precautionary measures should be adopted and provision made for its use. This can be done by so casting the bearing shells that numerous passages, broad and flat in cross-section, would surround the journal. The entrance to these passages could be fitted with appropriate threaded nipples which would permit of the ready attachment of an ordinary hose, and thus water could be rapidly forced through when the bearing heats seriously. The same device is now successfully used on friction brakes where far more heat is developed than in the ordinary bearing, even one of the largest size, and yet the rubbing surfaces of the brake are kept so cool that they may be made of wood and at the same time be very durable. Such construction would not greatly increase the cost of a bearing, and yet would reduce to a minimum the chances of overheating.

Police-Calls.—Mr. Henry Norman, of Grosvenor-road, S.W., has written to the *Times* saying that one night last week he walked home and found his housekeeper guarding the premises with a tomahawk which once belonged to Sitting

Digitized by Google

Bull, and which ought to have formed part of an Indian trophy in Mr. Norman's hall. She informed that gentleman that five burglars had been trying to force their way into the backs of the two houses next door. Mr. Norman adds, "One point in this connection is of public interest. In common with many other people I have an electric call-box in my house, for which I pay a guinea a year, by means of which I am supposed to be able to summon the fire brigade, a doctor, and the police; and the District Messenger Service and News Company, Limited, make a great point in their circulars of the importance of such facilities. Last night my housekeeper immediately rang the police-call. More than 15 minutes later a messenger boy put in an appearance to enquire what was wanted, vouchsafing the explanation that they did not answer the police-calls as the boxes were often 'messed about.' The call-box is extremely useful for summoning messengers or cabs, but if this experience I have described is the result of the company's instructions, and not the freak of an individual subordinate, it is well that the large number of people who have these call-boxes should know that in the matter of police, at any rate, they are leaning upon a reed." On the same subject Mr. Cumming Macdona, M.P., writes: "Upon reading Mr. Henry Norman's interesting letter I felt I must test the indicator in my house, and forthwith turned the point to 'policeman,' and in due course appeared the ordinary little boy asking what I wanted. I had a yearning to try the 'fire-engine,' but fearing too big a crowd might on Bank Holiday result had the notice 'caught on.'" The "ordinary little boy" is hardly an efficient substitute for a policeman, but there are very possibly two sides to the question, as the company are not supposed to keep a supply of police constables in stock at their offices.

Communication Between Railway Carriages.—Sir Courtenay Boyle, on behalf of the Railway Department of the Board of Trade, has addressed a letter to the secretary of the Railway Association on the subject of the recent outrage on the Brighton line. He states that the Board of Trade feel assured that both the directors and the officers of the railway companies would gladly take any measures which would be likely to prevent such assaults, and invites the Railway Association to be good enough to take the subject into serious consideration, and favour the Department with the result of their deliberations. A member of the House of Commons had suggested the desirability of making such alterations in the structure of carriage compartments as would prevent the perpetration of these outrages. It is possible that this pointed to the substitution of the corridor car for the ordinary railway carriage. The Board of Trade are aware that railway companies interested in long-distance traffic have this subject under their consideration, and that on general grounds for the comfort and convenience of the travelling public they are building and bringing into use corridor cars and corridor trains. The Department is not aware, however, whether the companies propose gradually to supersede the ordinary form of railway carriage by the introduction of cars for short-distance as well as long-distance traffic. Until corridor cars become general for long-distance traffic, or, at any rate, on trains running considerable distances without stopping, the question of the improvement of the means of communication between the passengers and the servants of the company in charge of the train must remain an important subject for consideration, and the Board will be glad to know whether the companies have recently made experiments with electrical or other means of communication, and, if so, with what results. We trust that the matter will be well ventilated, and feel sure that the adoption of an electric system rather than that of the cord now so much used would be appreciated by the public. The point at which the signalling apparatus is to be handled should certainly be inside the carriage, and should be so arranged that a violent wrench in any direction should give the signal to the guard.

Smoke Prevention.—The Committee for Testing Smoke-Preventing Appliances have issued a report. This committee was made up of Sir Frederick Abel, Sir Isaac Lowthian Bell, Mr. R. Forbes Carpenter, Sir Douglas Galton, Dr. J. H. Gladstone, Sir W. H. Houldsworth, Mr. A. Vernon Harcourt, Mr. J. W. Holden, Prof. Oliver Lodge, Lord Rayleigh, Prof. Roberts-Austen, Sir Robert Rawlinson, Sir H. E. Roscoe, and other experts, many Northern manufacturers, several North-country mayors, a couple of bishops, and a sprinkling of lords, including Lord Derby and the Duke of Westminster. Mr. A. E. Fletcher was the chairman. They enlisted the services of Prof. A. B. Kennedy, under whose supervision a number of tests were made near London. Afterwards it was determined to bring the testing apparatus from London, and the hon. secretary (Mr. Herbert Fletcher, of Bolton) undertook to superintend the engineering portion of the tests, while the chairman (Mr. A. E. Fletcher) undertook the chemical part of the work. The committee have been disappointed at the smallness of the support they received from steam users, in whose interests the work was undertaken. In their report the committee express their conviction that in the great majority of cases the black smoke thrown into the air during the combustion of coal is preventible, either by hand or mechanical firing, and without great cost to the consumer. Often the prevention of smoke is accompanied with a saving of expense. (It will be noted that the committee do not guarantee that it is always or even generally so.) Where firebars have an automatic reciprocating motion, an inferior and cheaper quality of coal can be used. From a perusal of the tables appended to the report it appears that the consumption of fuel was lower in boilers fired by machine than in those fired by hand, other conditions remaining equal, but the committee naturally avoid naming for recommendation any of the various appliances. Under the existing law—the Public Health Act of 1875—the action of discharging black smoke is made criminal, so that it remains only that the law shall be so far supported by public opinion that its application may be more general. In view of the fact that black smoke continues, nevertheless, to be discharged, it would have been interesting if the committee had been able to state how far the *a priori* conclusion that smoke consumption must necessarily be attended by increased economy in working was actually justified by experience.

Sir William Grove.—It is with regret that we record the death of Sir William Grove at his residence in Harley-street on Saturday last. Sir William Grove was born at Swansea in 1811, and was consequently in his eighty-sixth year at the time of his death. He was an Oxford man—his degree dates from 1830—and in those days Oxford was one of the most unpromising places in the world for a man of science to issue from, and that combined with the rarity of a great lawyer being eminent outside his own profession makes the position of Sir William Grove and the work done by him in the world of science the more remarkable. So usual is this that his scientific work was even at times forgotten by counsel, and on at least one occasion Mr. Justice Grove had to listen to arguments showing the practical impossibility of making small measurements—small measurements which were not more than a hundred times larger than ones he had constantly made himself. Mr. Grove was called to

Digitized by Google

the Bar in 1835, and his electrical researches date from the next few years. It is difficult to realise the state of things in those days, when the conservation of energy was not axiomatic, electric measurements were made anyhow or not at all, and men spoke vaguely of "coupling up for quantity or intensity." In 1839 Grove brought out his battery, the value of which to electrical progress in those days before the dynamo can hardly be over-rated. Next year he was appointed professor of experimental philosophy at the Royal Institution, a post which he occupied for seven years. There in the course of a series of lectures he advanced the doctrine of the convertibility of the various natural forces, which afterwards resulted in the publication in 1846 of the "Correlation of the Physical Forces." About this time Mr. Grove was elected a Fellow of the Royal Society, and in 1847 obtained the Royal Society medal for his Bakerian lecture on voltaic ignition and on the decomposition of water. In 1866 he was president of the British Association at Nottingham, the subject of his address being "The Continuity of Natural Phenomena." As late as March, 1891, he made a noteworthy speech at the Chemical Society's jubilee, and, so far as his judicial work permitted, he was always constant to the Royal Institution. Of the legal side of his history it need only be said that in 1871, according to the English practice, the flourishing advocate crowned his career by being made a judge. He retired from the Bench in 1887, after 16 years' service. He was a member of the academies of Rome and Turin, and Oxford in 1875 conferred upon him the distinction of an honorary degree. Sir William Grove married in 1837 a daughter of Mr. J. D. Powles, and leaves sons and grandsons to regret him.

The Institution of Junior Engineers.—The summer meeting of the above society has been arranged to commence on 14th inst., when the members proceed to Scotland. As will be noticed from the adjoining programme, those who join the meeting must be on business bent. Only one day is given solely to pleasure excursions, and a large number of works will be open for inspection. There is no better way of gaining experience than by visiting works in progress and manufacturing firms. The following is the outline programme: Friday evening, August 14—Saloon carriage and other reserved accommodation by train leaving St. Pancras, for conveyance of members attending the meeting from London. Saturday and Sunday—Edinburgh. Visit places of popular interest, including the Castle, Holyrood Palace, Arthur's Seat, etc. The gasworks and electric lighting stations may also be seen. Monday—Visit the Forth Bridge, through facilities afforded by the Forth Bridge Railway Company. In the evening proceed to Glasgow. Tuesday—In the morning the following works in Glasgow will be open for visiting, the selection being left with the members, who are requested to inform the secretary which works they intend to visit: hydraulic pumping station; new Howe Machine Company's cycle works; Mr. J. White's optical, nautical, electrical, telegraphic, and surveying instruments factory; sewage purification works; Messrs. Neilson and Co.'s locomotive works, Springburn. In the afternoon the members will be received in the Municipal Buildings by the Hon. the Lord Provost and the Corporation, afterwards being entertained to an excursion to visit one of the new reservoirs of the Glasgow Corporation waterworks. Wednesday—Excursion to Dumbarton. Reception by the Provost and Town Council, by whom the members are also invited to drive round the historic portions of the town. Luncheon at the Leven Shipyard, by invitation of Messrs. Denny. In the afternoon inspect their various works, experimental tank, etc. Thursday—Steamer excursion on the Clyde or on Loch Lomond. Friday—The following works will be open for visiting, the selection being left with the members, who are requested to inform the secretary which works they intend to visit: Singer Manufacturing Company's sewing-machine works, Kilbowie; Caledonian Railway locomotive works, St. Rollox; Fairfield Shipbuilding and Engineering Company's works, Govan; Messrs. Mavor and Coulson's electrical engineering works, Glasgow; Glasgow Iron and Steel Company's works, Wishaw. In the evening the institution's summer dinner will be held at the Alexandra Hotel, Glasgow, the president, Mr. Archibald Denny, in the chair, and the Right Hon. Lord Kelvin the guest of the evening. Saturday, August 22—Visit in the morning Dawsholm gasworks or the electric lighting station, Glasgow. In the afternoon, train, with reserved accommodation, returns to St. Pancras, arriving at 10.45 p.m.

Fire Calls.—The Post Office authorities have been giving trouble on the subject of fire-alarm calls. Some time ago they objected to the private telegraph set up for their own use by the Ashford fire brigade, and the result has been one of Mr. Henniker-Heaton's long and categorical questions in the House of Commons. Last week that gentleman said he would ask the Secretary to the Treasury (Mr. Hanbury), as representing the Postmaster-General, "whether he is aware that communication had been established by means of electric bell circuits between the fire station at Ashford and the residences of the officers and members of the brigade, and also between the fire station and the police station; that, similarly, electric bell communication has been established between a very large number of fire brigade stations throughout the kingdom and the residences of their members and the local police stations; and that such communication is maintained without charge solely for the purpose of facilitating the prompt extinction of fire and the saving of life and property; whether the postal authorities in March last gave notice to the fire brigade at Ashford, and to the other fire brigades above referred to, that the use of electric bell communication for the purposes aforesaid was an infringement of the Postmaster-General's exclusive telegraphic rights under the Telegraph Act of 1869, 32 and 33 Vic., c. 73, and further stated that the Department was prepared to undertake the provision of such circuits; whether he is aware that the electric bell communication referred to is employed without charge for transmission, and that the Department could in no case derive any profit from it; and whether, if advised that a technical breach of his telegraphic rights has occurred in these cases, he will, nevertheless, waive his rights in the matter and remit all fines and penalties incurred; or, if this should be impossible, introduce a short Bill enabling him to do so?" The Secretary to the Treasury's answer was: "The Postmaster-General is aware of the existence of the communications referred to in the first paragraph of the hon. Member's question. He is also aware that the object of such communications is to facilitate the prompt extinction of fires and the saving of life and property, and that at Ashford, and, as a rule, elsewhere, no charge is made for their use. It is the fact that the notice referred to in the second paragraph was given in the case of Ashford. The Postmaster-General is advised that the telegraphs which have been provided at Ashford constitute an infringement of his exclusive rights, but it is not a case in which he would think of imposing onerous conditions, or of exacting fines and penalties, and he has no doubt that the matter can be suitably arranged with the local authorities." If so, what outside the domains of red-tape was the good of worrying the local authorities on the subject. A somewhat similar communication to the Ashford one has formed the subject of discussion in the Kingston-on-Thames Town Council.

RAILWAY BLOCK SIGNALLING.

BY J. PIGG.

(Continued from page 96.)

SIGNAL LIGHT INDICATORS.

During darkness the arm of a signal-post is replaced as a signal to drivers by a light which is invariably red for "danger," and is green or white when the line is clear for an oncoming train. Where signals are at a distance from the cabin and the back lights are not visible, the existence of the light is indicated.

The apparatus employed for this purpose is of a simple character, and is shown by Fig. 31. It consists of an expansion bar, *a*, formed of an iron rod passing through a copper tube which is fixed above the flame of the lamp.

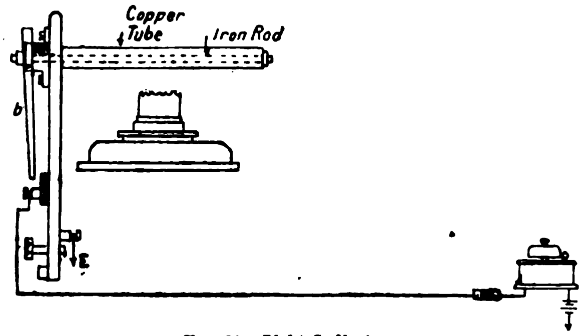

FIG. 31.—Light Indicator.

The difference in the coefficients of expansion of iron and copper cause the former to exert a pull on the short end of the lever, *b*, and separates the contact points. The expansion bar is connected to a small make and break bell and battery placed in the cabin by a special wire. If the light goes out from any cause, the expansion bar cools, and the bar, *b*, is brought into contact with the terminal base, and the bell begins to ring and will continue to do so until the light is re-established. A small peg switch is provided, so that the circuit may be disconnected during the time the lamp is not alight.

In other cases the bell is supplemented by an indicator showing "Light in" and "Light out." The "Light in" signal is maintained by a continuous current, and the indicator circuit is arranged as a shunt on the bell connections, as shown in Fig. 31A. In this way the bell is rendered silent during the time the indicator shows "Light in"; but should the light go out or anything occur to

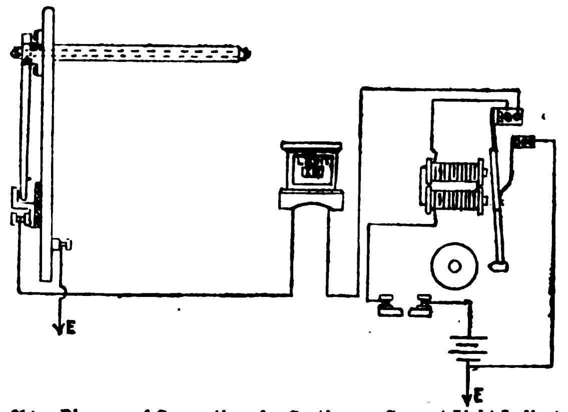

FIG. 31A.—Diagram of Connections for Continuous Current Light Indicator.

nterrupt the circuit, the continuous ringing of the bell draws the signalman's attention to the new position of the indicator.

"DISTANT" SIGNAL LIGHTS.

The form of the arm of a "distant" signal is slightly different to that of "home" or "advance" signals in being cut at the outer end, as shown in Fig. 27. This difference in form is made in order that the difference in the signals may be more easily identified, and to accentuate the difference existing in the character of these signals. "Distant" signals are passed whether "off" or "on"; "home" or "advance" signals must not be passed under ordinary circumstances when "on." The two latter signals are essentially "stop" signals; the former is not.

In order that a similar distinction may exist between the lights of "distant" and other signals the apparatus shown by Fig. 32 is being introduced by Messrs. Stevens and Sons, the railway signal engineers, for the purpose of changing the fixed light now in use to one of a "flashing" character. The lamp is of the usual construction, but in front of the light is placed a circular disc, *a*, to which an

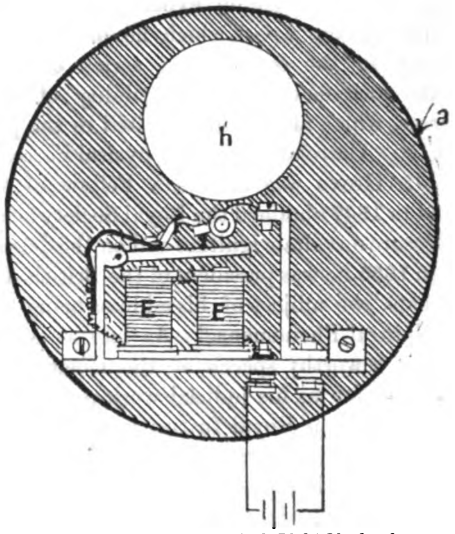

FIG. 32.—Distant Signal Flash Light Mechanism.

oscillatory movement is imparted by the motion of the armature of the electromagnet, E. The apparatus is of a simple make and break character, the interruption of the circuit taking place between *f* and *g*. A circular hole is cut in the disc, *a*, at *h*, and this is placed on a level with the flame of the lamp. The movement of the disc causes the light to be alternately covered and uncovered, the return motion being obtained by the aid of the greater weight of the lower portion of the disc.

As already intimated, the apparatus is as yet only in the experimental stage, and it is therefore too early to discuss its suitability or otherwise. At the same time it may be said that signals fitted with such an apparatus as at present constructed would require to have the "flashing" indicated in the cabin, in addition to the indicating of the existence of the light. Moreover, the "flashing" would require indicating for signals which under ordinary circumstances

FIG. 33.

are in plain sight, for the reason that the apparatus does not "flash" the back light, which is the only part the signalman can see.

POINTS INDICATORS.

It sometimes happens that "points" are placed in positions where they cannot be seen by the signalman. In such cases the apparatus shown by Fig. 33 is sometimes used.

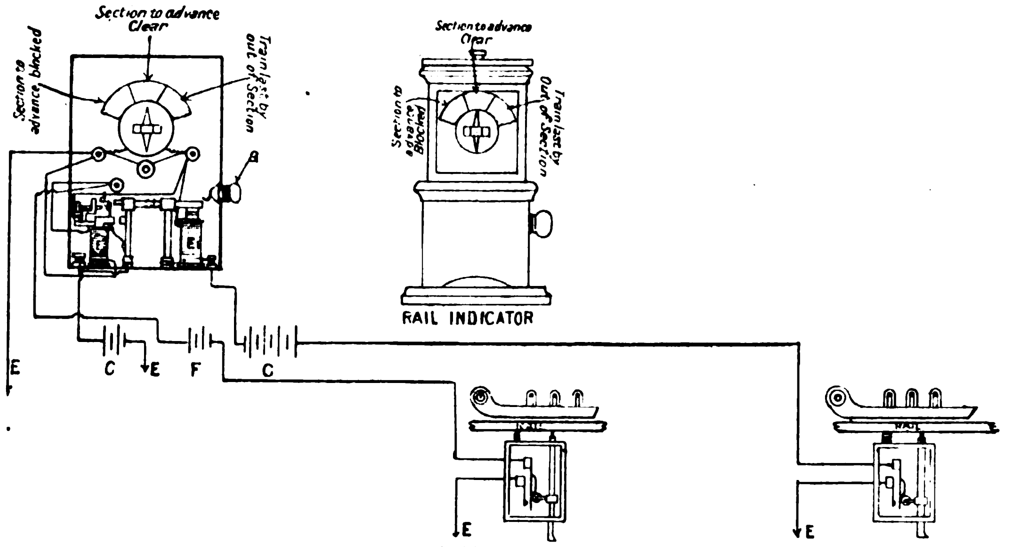
INDICATING THE SECTION BETWEEN CABIN AND "ADVANCE" SIGNAL.

It frequently happens that whilst the arm of an "advance" signal is visible from the signal cabin, owing to its being

Digitized by Google

placed on a comparatively high post, the base, and a part of the line cannot be seen on account of some object, such as a bridge crossing the line, intervening. In such cases there is a possibility of a short train, standing at the "advance," being forgotten, and another train being sent into its rear. The apparatus shown by Fig. 34 is intended to minimise the danger arising in this way by indicating a section of the line, which commences somewhere near the cabin, and terminates at a point a little beyond the "advance" signal.

The apparatus consists of two rail contacts fixed at selected points, and an indicator. Line wires are run to each rail contact. When a train passes over the first rail contact the parallel bar is displaced by the flange of the wheel, and the magnet, E, is energised by current from the battery F. The armature of E is attracted, and the rocking bar, *b*, falls, locking the armature, and thus maintaining the local circuit through the battery C, *d*, and the indicator coils, and displaying the signal, "Section to 'advance' blocked." When the train passes over the second rail contact the electromagnet, E, is energised by the current from the battery G, the rocking bar is raised and the armature of E released, the local circuit of the battery C is broken and the needle of the indicator points to "Train passing out of section," which indication is maintained until the last vehicle, *in motion*, has passed over the rail contact. The normal position of the needle when no current is passing is "Section to 'advance' clear." The knob, *a*, at the side of the instrument is provided for the mechanical release of the rocking bar, *b*, from the position indicating "Section to 'advance' blocked" for cases where a train, having passed over the first rail contact, has shunted into a siding without having passed over the second. This last arrangement detracts somewhat the value of the apparatus as an automatic arrangement. It will be noticed that there are three batteries to provide two deflections only. The work of the local battery, C, might with a slight rearrangement of the connections be performed by the battery F.



Contact Blocking Section to Advance. Contact Clearing Section to Advance.

FIG. 34.

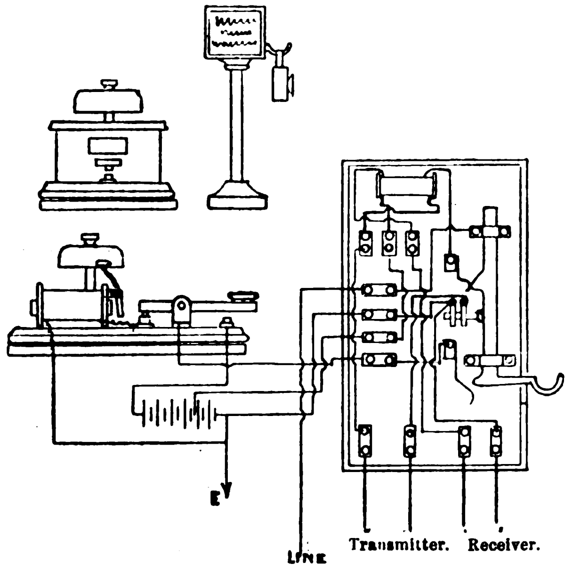


FIG. 35.—Block Bell and Telephone Circuit.

RAIL CONTACTS.

Rail contacts are not as yet so important a feature of railway signalling as they are probably destined to be when the apparatus used assumes a more automatic character than it possesses at present. One form of rail contact is shown by Fig. 34, in which the flanges of the wheels of a passing train are made to impart a horizontal movement to a bar laid parallel with and close to the rail, the return motion being obtained by a massive spring

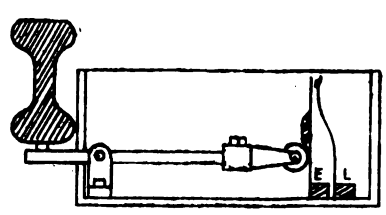

FIG. 36.

acting against the motion imparted by the train. Most rail contacts, however, are made to take advantage of the deflection of the rail by the weight of a passing train, in order to obtain the movement necessary for an intermittent connection. Several forms of rail contact suggested and used for various purposes are shown by Figs. 36, 37, 38, 39 and 40, and 41.

Rail contacts differ slightly in accordance with the character of the signal they are intended to provide for.

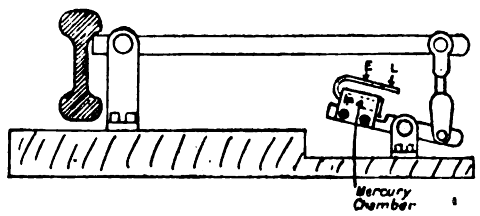

FIG. 37.—Circuit Broken.

Some forms only make contact during the time the rail is sufficiently depressed; others make contact for a longer period. Figs. 36 and 37 are examples of the first division. In the form shown by Fig. 37 the two connecting wires are sealed into one end of small chamber containing mercury, and the link work is arranged so that the mercury covers the ends exposed inside the chamber when the rail is pressed down. In this form a deflection of the rail of $\frac{1}{8}$in. is sufficient to make the necessary contact.

Digitized by Google

Owing to the small deflection required, the outer lever is practically steady during the passage of a train.

Fig. 38 is an example of the form of rail contact, by which a more prolonged contact is obtained. The contact-making apparatus consists of two mercury-cups to which the wires are connected. When the rail is depressed, a metallic bridge-piece dips into the mercury-cups and completes the circuits. The lever arm carrying the metallic bridge is pivoted at or near its centre, and carries at the opposite end a semi-circular, perforated bowl, which under normal conditions dips into a vessel containing paraffin oil. When the rail is depressed the bowl is raised into the position shown, and is emptied of oil at the same time. When the train has passed over and left the plunger free the bowl slowly fills with oil and sinks, and by raising the metallic bridge out of the mercury-cups breaks the circuit. By proportioning the number and size of the perforations a contact for any desired length of time may be obtained.

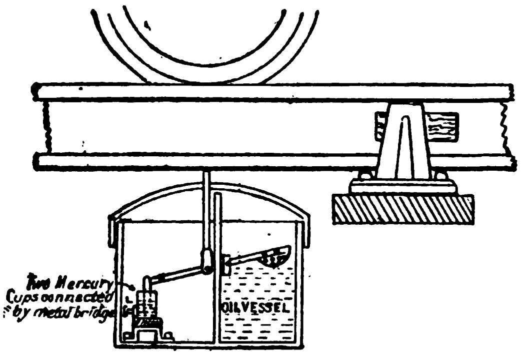

Fig. 38.—Circuit Closed.

Another form of mercury contact-maker, shown by Figs. 39 and 40, is that used by Messrs. Saxby and Farmer in connection with their system of interlocking the mechanical "advance" or "starting" signal with the block instrument. In this form the vertical motion of the rail is made to impart a horizontal motion to the mercury-cup, and the alteration of the level of the mercury brings it into contact with the curved metallic bridge seen in Fig. 40. The lever worked direct from the rail is locked with it, as will be seen from Fig. 39, and the return motion is also imparted by the rail.

Siemens's form of rail contact, shown by Fig. 41, is capable of giving a more or less prolonged contact by the depression of the rail. In this form mercury is also used to make the contact, and it is pumped, by the deflection of the rail, to a slightly higher level than the normal, in order

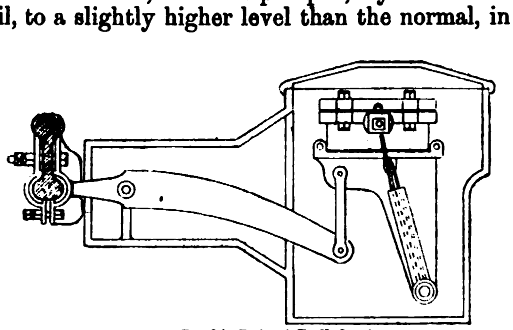

Fig. 39.—Buck's Patent Rail Contact.

to bring it into contact with the projected connection to which the line wire is connected. The spring-plate, *b*, is flexible, and on the deflection of the rail the mercury is forced up the tube, *h*, and into the small chamber, *c*. When the rail is released, the mercury runs through the hole, *s*, into the larger chamber and breaks the circuit. The difference in the levels of the mercury in the large chamber, and under the spring-plate, *b*, ensures the latter keeping the plunger, P, in contact with the under side of the rail, when the latter is not depressed. An indiarubber ring, *a*, is placed under the rail in order to exclude dust or grit which might impede the free working of the plunger. The apparatus is shown attached to a flat-bottomed rail, but it would equally be as easily fixed to one of the ordinary double-headed form.

Considering the forms of rail contact shown, and some of the duties they have, or may have in the future, to perform, it will be seen that they are, as has often been pointed out, defective, in that the first vehicle passing over the contact performs the duty which should be done by the last. "Last vehicle," in this case, implies something more than the last which passes a certain point, since it is quite possible for a train to divide and one portion to be left standing in such a position as constitutes it a danger to a succeeding train.

Consider, by way of example, the case for which the instrument and arrangement of rail contacts shown by Fig. 34 is intended, and assume that a short train is standing at an "advance" on a sharp curve, and out of sight of the signalman. So long as no part of the train has passed over the second contact, the indicator will remind the signalman of the presence of the train; but if only a part

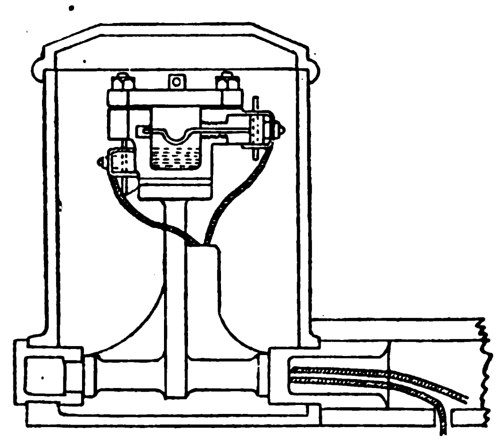

Fig. 40.—Buck's Patent Rail Contact.

of the train passes over the contact, the indicator will ultimately show "Section to advance clear." Under these circumstances the signalman would be justified in sending a succeeding train forward. It is true that the driver of the train is supposed to see that he has got the whole of his train with him, and it is also true that the guard on seeing a part of the train proceed forward should take steps to protect the part left standing; yet it is undeniable that most curious and, apparently, improbable combinations of circumstances are constantly arising. In any such event as that outlined, the indicator would be showing an incorrect signal.

It is, of course, a comparatively easy task to pick out defects in any form of apparatus intended for a specific purpose under varying conditions. These remarks, however, are only intended to show that the apparatus in

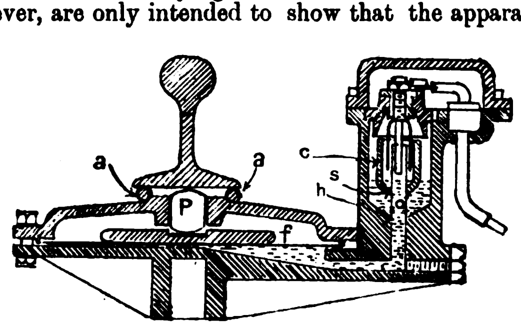

Fig. 41.—Siemens' Rail Contact.

use on railways for certain purposes is, in some cases, still in the evolutionary stage. Where rail contacts, of the forms shown in Figs. 36, 37, 38, 39 and 40, and 41, are intended to actuate apparatus which gives indications of the nature of "Line clear," they would appear to be ineffective in that they are unable to differentiate between the last vehicle of a train and any of the preceding vehicles.

In order to ensure the fullest possible protection to trains from apparatus, such as is shown in Fig. 34, or other apparatus indicating "Line clear," the last vehicle of every train should be capable of performing some duty that cannot be done by any other vehicle of that train. This, of course, involves the last vehicles being of a distinctive character to the others or provided with an attachment which shall be capable of performing for the indicating instruments the same function the tail lamp, or other "Last vehicle" signal, does for the signalman.

TELEPHONES ON BLOCK CIRCUITS.

The extensive use of telephones on railways has led to the trial of combined circuits for telephones and block bells, the latter being selected because the currents used for bell signalling are transient only. A form of switch used for this purpose is shown by Fig. 35. The arrangement, of course, admits of being used between two successive cabins only. The block bell is used as a means of call to the telephone.

(To be continued.)

TRAMWAYS INSTITUTE OF GREAT BRITAIN AND IRELAND.

The annual meeting of this institute was held on Friday last at the Holborn Restaurant, W.C.

The retiring president, Mr. Carruthers Wain, took the chair, and the SECRETARY (Mr. Elliot) read the annual report as follows:

The council congratulate the members upon the considerable improvement manifested in its financial condition as evidenced by the revenue account and balance-sheet. The receipts have exceeded the expenditure, and practically the institute is free from debt. The continuous attention of the council during the past 12 months has been exercised in the same direction as heretofore—*i.e.*, in the opposition to attempts at legislation opposed to the ideas of shareholders in tramway companies; but this opposition has not prevailed, although in association with others, against the passing of a measure for working by the London County Council of the London Tramways nor against the suspension, now to become permanent, of the standing order under which heretofore local authorities were not permitted to work tramway lines if they could be leased. Other Bills have been successfully opposed, such as the London Valuation Bill of the County Council, Mr. Schwann's Bill for the working of the tramways by municipalities, of the Eight Hours Bill as relating to tramways, and the Locomotives (Persons in Charge) Bill. Moreover, encouragement has been given to a special form of tramway enterprise—*i.e.*, light railways—the beneficial legislation in respect of which must undoubtedly have an influence for good upon the tramway enterprise of the future, and this leads the council to hope that the present restriction on the rate of speed upon tramways, whether urban or suburban, may be removed, and thereby enable the companies to give that which they and the public equally desire, a better service to the inhabitants of any districts. The council regard with satisfaction the changes in the views of the various local authorities as evidenced by the fact that in Birmingham an extension of tenure has been given to a company formed to acquire the existing Central Tramways; that in North Staffordshire a new life has been given to that company by the whole of the municipalities in the district, and that at Southport a renewed term of 21 years has been acquired by the tramway company. Other corporations have followed on the same lines, and the council are glad to note the change in the opinion of the London County Council as evidenced by the debates of last year.

The retiring CHAIRMAN then proposed the adoption of the report and accounts. The latter he would not refer to in detail in the presence of the Press. Considering the small length of tramway line there was in the United Kingdom compared with the United States it was surprising what a hold tramway questions seemed to have taken on the public. Briefly referring to American practice, Mr. Wain remarked on the readiness with which in that country they would take up work not five years old and throw it aside as obsolete. Their boldness appeared to be justified by the financial results. Much had been heard of horseless carriages, but up to the present the main result of the horseless carriage had been to put money into the pockets of promoters. They would have the horseless carriage, no doubt, some day; but although he and others were doing their very best with the help of the electrical engineers to supersede horses, he fully expected that the harmless necessary horse would remain as an important factor in both tramway and other traction. As an instance of a growing change of spirit on the part of local authorities towards tram companies, he was glad to notice that the Birmingham Corporation had granted a new lease of the tramways for 21 years to a Canadian syndicate. As to conduit systems, it had been said that they were an absolute failure. He did not, from his American experience, believe that to be the case, and specially mentioned the Washington trams as working economically and successfully. He felt that a great deal of the prejudice against electrical traction had been really due to the manner of its construction. This especially referred to the overhead system. That was a cause that could be removed, and consequently a prejudice that could be dissipated. In moving the report, Mr. Wain said that his resolution not to accept re-election as president was an irrevocable one.

Mr. WHITTAKER seconded the resolution, and it was carried.

Mr. CARRUTHERS WAIN proposed and Mr. WHITTAKER seconded the election of Mr. J. Fell (Leamington) as chairman for the ensuing year, Mr. Whittaker remarking that there were several reasons why he could not be a candidate for that post himself, although his name had been put forward.

Mr. COOMER proposed that the election should be deferred and the council be empowered to communicate with gentlemen who were not members of the institute. There was no insignificant portion of the tramway interest of the kingdom that was not at present represented in their institution, and he wished to bring them in if possible.

The suggestion was ruled out of order, and Mr. Fell elected. The latter gentleman in his reply spoke mainly of matters already dealt with by Mr. Wain.

The following gentlemen were elected vice-presidents: Messrs. W. J. Carruthers Wain, William Turton, and W. Mason. The following were appointed the Executive Committee: Messrs. R. Whittaker, J.P., John Waugh, Wilborn Stansfield, and John Coomer. Messrs. Whiting and Millington were elected auditors, and votes of thanks were accorded to the late president (Mr. Wain), to the late auditor (Mr. C. James), and to Mr. J. G. B. Elliot, the secretary of the institute.

The meeting then proceeded to the reading of papers and their discussion. The subjects and authors of these were given in a note in our last week's issue.

Mr. WESTMORELAND'S starter-brake was taken first, out of its turn. This paper was commendably short, at any rate. The principle is that the car is stopped by throwing into gear a mechanism which causes the revolving axle to compress a spiral spring, the resistance bringing the car to rest. The energy of the spring is utilised to revolve the axle and start the car again. The inventor showed a model and rode upon it. Regarded in the light of a toboggan it was rather uncomfortably small, but grossly overweighted as it was by its inventor it stopped beautifully, and ran its own length again at starting. Something similar has been tried, it is believed, by a tramway company in France. In the discussion the obvious point was taken that there would not be so much power available in a stoppage going uphill as on a level, and that there would be too much going down hill. In reply to the latter objection, the inventor remarked that going down hill the emergency brake was employed and not the starter-brake. In the unlikely case of the failure of the emergency brake, of course the starter-brake would be available to stop the car, but care would be required in starting again.

Mr. T. H. BRIGG then expressed at very great length his views on the mechanics of horse haulage. These amount to the idea that the trace is generally attached to the wrong place. We believe the practice that has prevailed since the forgotten epoch when the first horse was tamed can be justified mechanically without any difficulty, but the subject does not concern electrical engineers. It may be noted that incidentally he claimed that the horse was the cheapest and most economical motor going, and considered that it reflected unspeakable shame on the century that talked so much of science and technical education that neither at South Kensington nor anywhere else had the economic method of horse haulage been investigated. The subject greatly took the fancy of the meeting and consumed the bulk of the time available for the papers and discussion. When this was finished, it being nearly 4 o'clock, it was decided to discuss the other papers unread.

Mr. J. RAWLINS was not present, and his paper—much longer than Mr. Westmoreland's—on another car

Digitized by Google

starter passed without a word. Mr. Rawlins' starter-brake also works with a spring and is patented.

The next paper taken was Mr. FRANKLYN'S, on "The Brand Electric Railway System," of which the following is an abstract:

Electricity is acceded by all scientists to be the future motive power for travel. The following synopsis of the Brand electric railway system will fully demonstrate to the public in general its superiority over anything ever invented for the propulsion of street railways. Let us first take the present method employed in the overhead or trolley system. The trolley wherever employed is absolutely turning the streets of a city into one vast death-trap, inasmuch as it is distributing a death-dealing fluid broadcast over the streets, not only to man and beast but to everything beneath the earth in the shape of water, gas, and all metallic pipes—in fact, wherever conditions xist for the action of electrolysis.

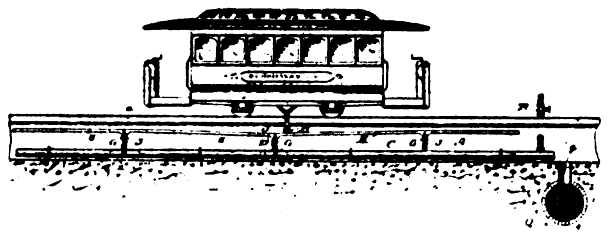

FIG. 1.

Now, the matter of absolutely overcoming and guarding against all the foregoing evils is positively accomplished in the Brand electric railway system, which, by referring to the working drawings, can be explained as follows : In introducing the Brand system we show the great advantages over all other inventions by its perfect immunity against atmospheric tunnel and earth influences, and which are known to be so detrimental to an electrical conductor carried underground.

In avoiding this great question of the loss of a current we clearly demonstrate the means employed. First, the perfect hermetically sealing, and thereby insulating the conductor. This, without any question, is the very fundamental principle of our system, and will necessarily follow in the perfecting of any system. Now to obtain this result, and at the same time to come in contact with the hermetically-sealed conductor, at all points and at all times, we employ the most simple and practical device known to the mechanical world—viz., the simple vertical movement of a piston or plunger working in conjunction with an hermetically sealing device, known as the simple flexible diaphragm. In the mechanical arrangements of all the parts strength and durability are the prominent features. The uncertainty of wire bondings and connections are avoided and used nowhere. First, in the trolley service conductor, rail is used from point to point of contact, whereby absolute certainty of electrical charging of the trolley service rail is accomplished at all points wherever a car may be stationed on the line.

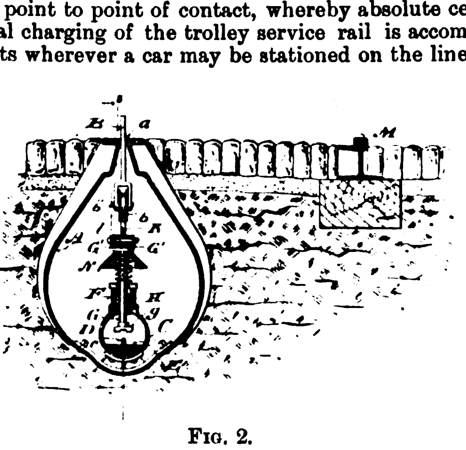

FIG. 2.

In the construction of the parts employed in this system great consideration has been given to compactness of the construction throughout, and avoids one of the great questions heretofore existing in other systems where the underground trolley system has been an experiment. We show that the parts in their entirety are accommodated in a 13½in. conduit or casing in height by 12in. in width. This brings the cost of this perfect underground system within reasonable figures, and nearly approaching, or even less than, a first-class construction of the overhead deadly trolley work. This will satisfy at once the demand of the public without cost to the operation of the traffic line in the large cities of the country, and further, as to the question of repairs, they are of such small consideration compared with that of the overhead system, that electrical and mechanical engineers unanimously endorse features herein employed as being of the highest efficiency.

In the construction of underground conduits for electric conductors for electric railway lines much difficulty has been heretofore experienced from the fact that by the ordinary forms of construction the wires are unprotected from dampness which accumulates in the conduits, and consequently short-circuiting or grounding of the current is liable to frequently occur. The object of our invention is to provide an underground conduit for electric railway conductors of such construction that the conductors will be effectually protected from dampness, said conductors being wholly enclosed with an airtight casing or covering, and provided with suitable means for making contact at intervals with said conductors, and for conveying current therefrom to the motor upon a car through the medium of movable service rails.

Referring to the accompanying drawings, Fig. 1 is a longitudinal sectional view of a conduit constructed in accordance

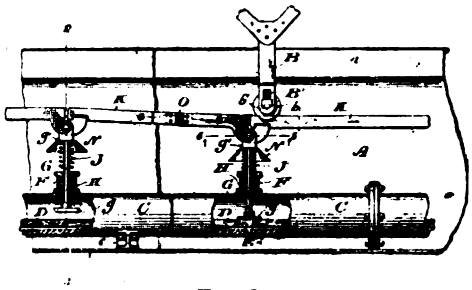

FIG. 3.

with our invention, and shows a car located upon a track and provided with a contact device in operative engagement with the service rail ; Fig. 2 is a transverse vertical sectional view of our improved conduit, taken on line 2—2 of Fig. 3 ; Fig. 3 is a longitudinal sectional view of the same taken on line 3—3 of Fig. 2 ; Fig. 4 is a detail vertical sectional view of a somewhat different form of device for normally holding the service rail out of contact with the conductors ; Fig. 5 is a horizontal sectional view illustrating the construction of the joint between adjacent sections of the service rail ; Fig. 6 is a detail plan view of a somewhat different form of construction of joint ; Fig. 7 is a side elevation of same ; Fig. 8 is a detail sectional view of a joint formed in the section of the service rail, said section being taken on line 8—8 of Fig. 3 ; Fig. 9 is a longitudinal detail sectional view, illustrating a somewhat form of conduit.

In the said drawings, A designates a suitable casing, preferably of metal, which is adapted to be located wholly beneath the surface of the ground, and is provided in its upper wall with a suitable slot, A, for the admission of a contact device, B. C designates a suitable tube or pipe, located in the lower part of the casing, A, and supported in position therein, in any suitable manner, as by means of the chairs, *c c*. A longitudinally extending conductor rail or wire, D, is located in the lower part of the tube or pipe, C, but insulated therefrom, said conductor being conveniently partly embedded in a suitable insulated material, E, which is located in the lower part of the pipe or tube, C. At suitable intervals along the upper side of the tube or pipe, C, we provide upwardly extending tubular connections, F F, through which vertically movable plungers, G G, are arranged to extend, said plungers carrying at their lower ends suitable contact shoes, *g g*, for electrical engagement with the upper or exposed portion of the conducting rail, D. As shown more particularly in Figs. 2 and 3, these plungers, G G, may be

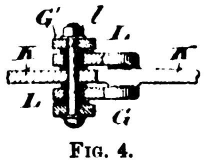

FIG. 4.

arranged to extend vertically through suitable glands or stuffing-boxes, H H, in the tubular extensions, F F, or, as shown in Fig. 4, said plungers may be arranged to extend downwardly through apertured elastic diaphragms, I, which are secured in any desired manner to the upper ends of the tubular extensions, F. Suitable springs, J J, are arranged around the upper portions of the plungers, G G, and are arranged to bear upwardly against suitable shoulders, $g^1 g^1$, thereon, said springs being arranged to rest at their lower ends upon suitable supports on the tubular connections, F F, so as to normally hold the plungers, G G, upward, with their contact shoes, *g g*, out of engagement with the conductor. To the upper ends of the plungers, G G, are suitably secured sections, K K, of the service rail, said sections being pivotally engaged with the upper ends of said plungers and with each other in the manner shown in the drawings. As shown more particularly in

Digitized by Google

Figs. 2, 3, and 5, the adjacent ends of the sections of the service rail are kept out of contact with each other by means of insulating washers, L L, suitable bolts or rivets, 1, being passed through the ends of the said sections and said washers, and secured in any desired manner, so as to flexibly connect the ends of the sections together. We find it convenient to make the upper ends of the plungers, G G, bifurcated as shown more particularly in Figs. 2 and 5, the furcations, G^1 G^1, thereof being arranged to embrace the ends of the sections of the conducting service rail. As shown more particularly in Figs. 2 and 5, we establish an electrical connection between each of the plungers, G G, and one end of the movable section of the service rail through the medium of the pivot pin or bolt, 1, which, while it is insulated from one movable section, has metallic contact with the bifurcated upper end of the plunger, and the apertured end of one section of the service rail. It follows from this construction

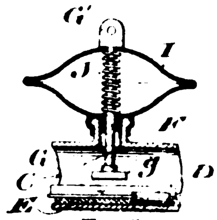

Fig. 5.

that by pressing downward upon any one section of the service rail, one of the plungers, G G, will be brought into electrical contact with the conductor, D, within the tube or pipe, C, at the bottom of the casing, and one section of the service rail will thereby be brought into electrical connection with said conductor.

In arranging the connections for the motor upon a car truck, said connections may be so made as to take current from the movable sections of the service rail through the motor, and to then pass the current to one of the track rails, M, in a familiar manner, or, if preferred, two tubular casings, C C, might be employed in the bottom of the main casing, and each arranged to contain a single conductor. It will be seen that as the car advances, the contact device, B, is brought into engagement successively with the several sections of the service rail, the said sections being depressed and brought into connection with

Fig. 6.

the conductor, L, as the contact device advances, and but one section, K, of the service rail being in circuit at one time. In order to enable the contact device to operate satisfactorily in depressing the several sections of the service rail, and at the same time ensure a perfect electrical contact with said section, we find it convenient to journal the roller, *b*, in movable boxes, b^1, which are pressed downwardly by a spring, B^1, so as to forcibly hold the roller, *b*, in engagement with the upper side of the service rail. As soon as the contact device has passed from one section of the service rail into engagement with the next adjacent section thereof, the springs supporting the plungers connected with the first-mentioned section will serve to automatically raise said plungers and said movable sections so as to break the electrical contact between the plungers and the conductor. If desired we may employ means such as shown in Figs. 6 and 7 for permitting the contact device to come

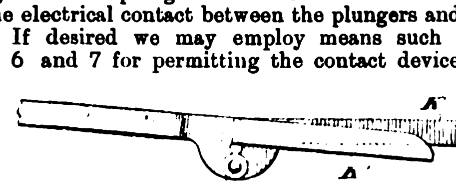

Fig. 7.

into engagement with the sections of the service rail before passing the joints between the adjacent ends of said sections, and to this end we find it convenient to arrange at one or both sides of the joint between said sections, suitable extensions, K^1, which are arranged to extend somewhat beyond the point of engagement between two sections, K K, of the rail, and into position for engagement by the contact roller a little before the joint is reached. In this manner, as the contact device approaches a joint in the service rail, and depresses the adjacent ends of the two sections connected by said joint, the rear end of the section with which the contact device engages will be free to rise about the time that the contact device reaches the joint, and as soon as the electrical connection of the rear of said section is broken, said section will, of course, be dead, while the next succeeding section will be in circuit, and it therefore follows that by the engagement of the contact device with the extension, K^1, of said next succeeding section, just before the point is reached, the contact device will be enabled to take current from said succeeding section, and a constant flow of current through the motor is thereby insured. This feature of our improvement is of especial importance upon grade, where an instant's break in the current might cause a stoppage of the car.

As shown more particularly in Fig. 2 of the drawings, we find it convenient to provide suitable means for protecting the movable parts from the accumulation of dirt which may find its way through the slot in the casing, A, and to this end we may provide suitable hoods, N, upon the upper ends of the plungers, G G, arranged to shed or deflect any dirt which may fall through the slot, and prevent the same finding its way into or upon the stuffing-boxes through which the plunger is passed, thereby guarding against undue wear on the stuffing or the moving parts. In the particular device shown in Fig. 4, however, no such precaution will be necessary, inasmuch as the upper part of the plunger is enclosed within the elastic diaphragm, 1, and all dirt is effectually excluded therefrom. If desired, I might employ between adjacent sections of the service rail suitable insulated joints such as shown in Fig. 3 and Fig. 8 at O, the connected ends of the sections being electrically

Fig. 8.

insulated from each other in a familiar manner. By this means the adjacent ends of the sections which are pivotally secured together might receive current from one plunger at the same time, the insulation in the joint between said sections being, of course, omitted. In the form of construction (shown in Fig. 9) I have illustrated the conductor, D, as enclosed in a suitable insulating cover, D^1, throughout the greater part of its length, but being bared at intervals, as at *d d*, and arranged to extend horizontally through suitable hollow casings, P P, within which the plungers, G G, are arranged to operate in the manner before described. In this form of construction, the entire housings, P P, as well as the insulated conductors, may be buried in a suitable cement or other material at the bottom of the casing, A, it being only necessary to arrange the housings

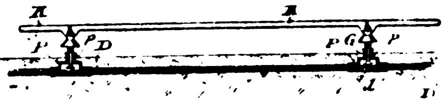

Fig. 9.

so as to permit the tubular extensions, *p p*, thereof to extend upward through said cement or other material so as to enable the plungers, G G, to engage therewith. By our improved construction, we are enabled to effectually protect the conductor against dampness and to thereby guard against accidental short-circuiting or grounding of the current and consequent derangement of the system. As a further and separate improvement we prefer to connect the main casing, A, at suitable intervals with a sewer, Q, by means of suitable tubular connections, *q*, so as to enable any accumulation of water within the casing to find its way out of the casing into the sewer.

As a still further and separate improvement we prefer to provide a suitable blast pipe, R, at any convenient point or points along the line of the conduit, and arranged to communicate with the interior of the tube or pipe, C, whereby a blast of hot or dry air may be forced through said pipe or tube to drive out any moisture that might find its way into the same on account of a leak in the pipe or tube.

Important questions and answers that are asked in connection with electrolytic action, and how it is absolutely overcome in the use of the "Brand" electric conduit tramway and railway system.

Q.—What is induction? A.—Dissipation of the current scattering broadcast in the earth.

Q.—What follows induction when the dissipation of the current is scattered in the earth? A.—Electrolysis.

Q.—What is the harmful action of electrolysis. A.—It destroys all metallic improvements such as gas and water pipes, paid for by the public tax.

Q.—How can this be prevented? A.—By the conductor carrying the current outward from the source of power, the dynamo, to any terminal or objective point, and returning the same through a thoroughly insulated cable back to the dynamo.

Q.—How can you do this? A.—Through an enclosing tube or pipe carried the entire length of the conductor, and the conductor hermetically sealed or enclosed therein, and the two together to locate within an open tunnel or conduit in the street.

Digitized by Google

Q.—How do we obtain the power of this current from within the hermetically sealed tube or pipe? A.—For the particular purpose of propelling street cars or trams by drawing the current off at spaced intervals 20ft. or more, and by inserting through the walls of this tube or pipe a copper contact post or piston, offering a direct and unfailing electrical contact for the passage of the electrical fluid up to the trolley and thence to the motor.

Q.—How much depression is needed or movement required through the wall of the tube or pipe to make contact? A.—Just enough movement is necessary for the piston to make and break the contact—under 600 voltage used in power service, ⅝in.

Q.—How is this accomplished? A.—By the means of a trolley wheel rolling upon the service rail as the car advances.

Q.—What breaks the contact? A.—The upward tendency of the spring in the diaphragm after the pressure produced by the trolley is relieved.

Q.—How do we seal the opening through the wall in the tube or pipe in which the plunger works or moves against the entrances of water, gases, dirt, etc.? A.—By the metallic flexible diaphragm (see drawing).

Q.—Is this durable? A.—Not being subject to any rubbing or wearing friction, in having only to depress the space of ⅝in. to allow the plunger to make the contact, the wear would be imperceptible year following year.

Q.—What will the flexible diaphragm be composed of? A.—What is known as spring-bronze metal, or galvanised spring metal of various kinds.

Q.—Will arcing take place under the foot of the piston at the instant contact is broken? A.—No; for the reason that as soon as the trolley passes midway between the plungers, contact is instantly made with the next plunger, and an arc will not span the space when one of these plungers is down.

Q.—Why? A.—Electricity will make no effort to reach over the space intervening between two points of metal when an absolute metal path of copper is made for it to follow, therefore an arc cannot form when the piston breaks contact with the conductor.

Q.—Why is it absolutely necessary that the electrical conductor should be hermetically sealed? A.—The earth is at all times a great induction magnet, constantly tending to rob a naked conductor of the electric fluid.

Q.—Will the tube used in this system prevent the wholesale robbery of the current? A.—Yes. Nothing could be more absolutely sure than the means here employed in the prevention of the current escaping into the earth, for the reason that all electric companies, telephone, fire alarm, telegraph, etc., are enclosing naked wires within tubes or pipes. This is a simple matter, providing they need not be tapped for the purpose of extracting the current, but in the case of street-car power, the current must be drawn at all times, and therefore drawn off at intervening points as shown.

Q.—Will the tube prevent dampness from interfering with the current? A.—Yes; by the simple means of an asphalte coating applied throughout its inner surface, or by means of an air-blast pipe (see Fig. 15 in plans) operated at the power-house, and a blast from a Sturtevant blower if necessary.

Q.—How will the current return to the dynamo so as to prevent escape and electrolytic action? A.—After being carefully provided against escape in its outward course it is returned through a perfectly insulated cable, located parallel with the conductor, and which can be located anywhere within the outer tunnel or conduit. This will ensure what is known as a metallic circuit from the dynamo out and back.

Q.—How will the current meet this return cable after performing its work through the motor? A.—When the current has passed through the motor it immediately seeks the earth through the axle and wheels of the car-truck, and to the track and rail, thence to the next rail, and so on through series of rails to the dynamo, barring what does not escape into the ground at each defective joint, at each and every rail. If these rails were jointless, or one continuous rail, they would offer a perfect conductor in themselves.

Q.—Why is a separate return cable better? A.—Because it is without joints, offers no place for escape on the current's return home, and in this return cable the current is caught up, and gathered from each rail by short cables branching on to this main cable, and allowing no current to escape into the ground, and the whole waste which is causing electrolysis is conveyed. After these vital questions have been put and answered, and everything showing the means of getting at the power of hermetically-sealed electricity, and using the same force, and returning it back to the point of beginning or its source, no objections should stand long in the light of an intelligent argument in favour of the "Brand system," where not only the electrical difficulties are absolutely overcome, but the mechanical difficulties also, and so palpably plainly, that little is left for the mind to grasp in its comprehension.

Prof. LUPTON opened the discussion. He was simply appalled at the delicate apparatus that the author proposed to put under the streets. An electrician of great skill might be able to make such apparatus, but where were the army of skilled men to come from to get into the tube and keep it in repair through all kinds of weather? Contact-makers had been devised before, and had had their day, and it would be interesting to hear why Mr. Brand's ingenious system was expected to have a longer life.

Like Thackeray's "Little Billee," Mr. STURGEON had been endeavouring to recite his "catechee," and he found it a stiff piece of work. It began, "What is induction?" and the answer was, "Dissipation of current scattering broadcast through the earth." After that he did not intend to follow the author of the paper through his ideas of electricity. The ⅝in. allowed between the collector and the point of contact might be sufficient at first if the line was laid very carefully indeed, but it would not be maintained when the rails and wheels began to wear, and the trolley would soon be jammed down on the electrical contact. The system appeared to have many of the disabilities of the overhead trolley system with several additional of its own.

Mr. SELLON could not help looking upon the paper as an attempt to put before a body of gentlemen who knew something of the subject a system the details of which were of the most amateur description. The statement that the trolley was turning the streets and cities into a death trap was simply an absolute absurdity. Mr. Sellon also referred to the "catechism" at the end of the paper. It reminded him of nothing so much as a book called "Brewer's Guide to Science," which had considerable vogue in the days of his childhood. They had discovered a little since those days, and if Mr. Brand's system of traction was on the same basis as the answers to questions at the end of the paper, he could only advise him to learn a little electricity. One thing only he would say—namely, that Mr. Brand's return was practically just the same as the ordinary return through the rails, and all that was said as to electrolysis was consequently wide of the mark.

There was no reply on behalf of the author. It is, however, right to say that in the way the papers were taken it was not very easy to tell when any one of them was likely to come on, and the author's absence may have been accidental.

The next paper was one by Mr. J. STURGEON on "Mechanical Haulage on Tramways." It was practically an advocacy of the cable system which mainly took the form of an attack on electric traction. The history of electrical traction for tramways had been one continuous record of financial failure. The accumulator system was introduced into Brussels with the usual flourish of trumpets, and had failed completely. Great hopes were entertained of the electric system in Birmingham. The expenses on that section had kept increasing, until last year they amounted to 18·43d. per car mile. These were accumulator systems, but electricians were just as cock-sure about those systems five years ago as they are about overhead and conduit electric systems to-day. The principle was still just the same—traction by adhesion of the wheels—only varied slightly in detail. In last year's report of the directors of the Chicago City Tramways the old familiar paragraph cropped up again in the expression of the surprise and disappointment of the directors to find that the working costs of the electric system (overhead) were 70 per cent. more than the cable, notwithstanding that the electric cars had the advantage of running at nearly double the speed, and they had no Board of Trade to interfere with them on behalf of the public safety. The Roundhay electric line had proved a complete financial breakdown. If ever an electric system had a fair chance of paying that had. The South Staffordshire Electric Tramway was worked by contract, and no outsider could tell what it really cost. It would be interesting to watch how recent electric concerns came out under the operation of the new Board of Trade rules, issued in March, 1894. These rules were very stringent, and if electric traction could hardly manage to keep up a brazen front when free from their operation, how long might they expect the recent installations to exist under them? As to electrical leakage and its destructive effects upon gas and water mains, etc., he would strongly advise all those who were

Digitized by Google

interested in the subject to read the evidence of Major Cardew, Dr. John Hopkinson, Mr. Preece, and Sir F. Bramwell before the Parliamentary Committee on the subject. In fact, overhead electric traction had already seen its best days, and was doomed to follow in the wake of the accumulator, so now there were signs and tokens of another new departure in the form of conduit systems of electric traction. A new era of experimenting in these systems had been entered upon. But there was nothing in the nature of underground or conduit systems that could in any way help to lessen the cost. It was a hopeless task that electric tractionists had taken upon themselves, and the new departure was bound to depart, too, on the same road as the others. Propulsion by the adhesion of the wheels was wrong in principle, and under the conditions of street traffic no method of traction by adhesion could possibly, from the very nature of things, compete with methods of traction by pulling with simple rolling action in the wheels of the vehicle. In a cable system they had to provide for the driving of the cable, and then could string on to it as many light cars as they liked, adding power only to overcome rolling friction. The cable itself was always in equilibrium and always in continuous motion in one direction, so that it might be regarded as a sort of flexible flywheel, with its weight distributed over many bearings instead of concentrated on one. The author then very briefly described a new form of "gripper," by which it was possible to diminish the depth of the conduit and the interference with the streets in laying it.

Prof. LUPTON, from experience in mining work, maintained the excellence of the endless cable system. Miners were often carried miles underground to their work, so his experience really covered the case of passenger traffic. It was an advantage of the cable system that there was "no electricity grinding, and the power went direct to the work to be done." Also putting on additional cars made little additional work.

Mr. SCOTT RUSSELL considered there was room for both electric and cable systems. Owing to the power required to run the cable the latter was out of the question when there was not a frequent service.

Mr. SELLON, in reference to the comparison of the cable to a flywheel, said that he had yet to learn that it took 40 to 50 per cent. of the power of an engine to drive its flywheel. If so, it was another entirely new point in mechanics. As to the Roundhay line, it was only put up as an advertisement. It began at one place and ended nowhere; but its working figures were, as a matter of fact, very successful. In order to discredit overhead electric traction, Mr. Sturgeon had brought forward cases where accumulator traction had been a failure. What had that to do with it? The eminent electrical authorities whose names had been referred to in connection with the committee happened to be all engaged on behalf of telephone or gas and water interests. The conclusion arrived at was that under the Board of Trade regulations as now in force there would be no electrolytic action. Electric tramways, as a matter of fact, could and did conform to those regulations. The amount of electrical leakage was not a matter of speculation, for what there was had to be measured and the recorded amount forwarded to the Board of Trade every week. He was quite prepared to admit the advantages of the cable system when there was a very large amount of traffic. Finally, if the cable system was so good there was no necessity for Mr. Sturgeon to have devoted so much space to condemning electricity. He (Mr. Sellon) would have preferred to have had some figures and particulars showing that the cable system produced better results.

The AUTHOR (Mr. Sturgeon) replied. He had intended to consider only tramway traction in towns, which implied a frequent service. Electric traction might do for a suburban line with a service of four cars an hour. Additional cars could be easily put in a cable system, but on the electric system the "resistance goes up in proportion to the square of the current." (This was how it was put, but the meaning is obvious.) The American electric lines depended for success on high speed, high voltage, and high fares, and were allowed to kill people in a way that would not be permitted here.

Papers on tramcar check-tickets, harness, horseshoes, and bells and seats completed the list.

The annual dinner of the institute took place the same evening at the Holborn Restaurant, the new president occupying the chair. The invitation was to meet the Right Hon. C. T. Ritchie, M.P., President of the Local Government Board, but that gentleman was prevented being present by the pressure of parliamentary business. A similar cause probably kept away Mr. Pritchard Morgan, M.P., but Mr. Atherley Jones, M.P., was there, as were also Sir John Puleston, Mr. H. C. Godfrey, Mr. W. J. Carruthers Wain, Mr. W. Mason, Mr. N. Scott Russell, Mr. E. Garcke, Mr. R. A. Germaine, Mr. J. W. Clydesdale, Mr. Bassett Hopkins, Mr. T. H. Bolton, and Dr. Ginsburg.

Mr. T. H. BOLTON proposed the toast of "The Houses of Parliament," and this was replied to by Mr. ATHERLEY JONES, who referred to legislation in progress with a view to the development of light railways, tramways, and motor-carts, which showed that the institution had a wide field of work before it.

Mr. GODFREY having proposed "The Local Authorities," Mr. BASSETT HOPKINS replied.

Sir JOHN PULESTON proposed "The Tramways Institute," remarking that at one time it was very difficult to exploit a tramway in this country; but now it had come to pass that no one would wish to be without trams. The Tramways Institute had done much to bring this about. In view of the interest of the public, he regretted the legislative restrictions that were imposed upon tramway traffic. He was of opinion that one of the restrictions which was most irksome was that which prohibited tramcars being propelled at more than eight miles an hour, which was, he thought, a speed that might approximately be doubled without inconvenience or danger to the public. The progress made by tramways in this country had been very great, and at no time had that progress been more manifest than it was now. So that when they next met he hoped they would be able to congratulate themselves on the success of a new mode of traction which would still further improve the tramway service.

Mr. CARRUTHERS WAIN replied, and referred to the work of the institute in watching and preventing legislation injurious to tramway interests.

Mr. HAMMERSLEY (Hanley) proposed "Traction: The Survival of the Fittest." He hoped the survival of the fittest meant the system of overhead electric traction adopted in his district with the help of Mr. Garcke and Mr. Sellon, and he was quite certain it meant the survival of the Tramways Institute.

Mr. HAMMOND replied to this toast. As to what would survive in the future, so far as tramway traction was concerned, he was certain it would not be the horse. As an electrical engineer, he considered the field of traction one of immense interest, and he would willingly exchange two or three lighting retainers for one traction retainer. He had been connected with electric lighting from the very first and the problems of distribution which it involved, but he thought that in the future the greatest problem of the distribution of electrical power would be its distribution to the moving tramcar. The horse required a good deal to keep, and involved using as much force to pull a light car as a full one. The greatest force at their disposal was that contained in the coal measures, and the best way of utilising it was the central station and electrical distribution. Therefore he thought the traction of the future would be electric traction.

Mr. MASON proposed "Kindred Institutions," for which Mr. N. SCOTT RUSSELL, M.I.C.E., replied, and other toasts were "The Visitors," "The Press," and "The President."

A programme of music was arranged under the direction of the secretary, Mr. Elliot.

Accident.—It is stated that last week, on the Budapest underground electric railway, one of the carriages, in which were six passengers and two railway employés in charge, suddenly took fire as it was travelling rapidly. The terminus was reached, but the car was totally destroyed at the end of the journey. The passengers were naturally frightened, and the men in charge sustained some injury.

WORK v. FINANCE.

In a recent issue we gave the views of our Consul at Bilbao, that English firms were allowing business to pass by and to fall into the hands of competitors. No doubt there is a large amount of truth in this; but, without at the present moment enquiring specially into the case of the Bilbao district, it may not be amiss to discuss the question as it presents itself to many of our manufacturers. The first aim of a business man is to obtain business, and under ordinary circumstances he will leave no stone unturned to get any work that may be going. Electrical engineering, however, does not run upon commonplace lines. It is not so much a question of work going a-begging as of making work. We may illustrate the method of procedure by a specific example, one, indeed, of many, any one of which would prove our case. Assume you have a pushing young man wanting to make a little money or earn a position in a town not too well favoured with artificial light. He thinks "electric light" will go, makes a few enquiries, gets a few promises of support, and then goes about to financiers or manufacturers with a crude scheme suggesting that they should take it up for a consideration. If a manufacturer on going into the matter imagines that it may prove successful and decides to assist the applicant, he has in the first place to arrange the financial question, for upon this depends the work. It is not the case of someone coming to him with money in their hands seeking quotations, as it is the finance of probably successful schemes in order to obtain work for his factories. We need not point out the result of these financial transactions—that is well known, the effect being often doubtful paper profits, locked-up capital, hence larger capital required than would be wanted if manufacturing was the only business of the firm. If a financier takes up the matter he frequently takes it up in conjunction with the manufacturer, and he has to take his risks and his profits. Altogether, then, many of the schemes are fearfully overloaded at the start, and it is a wonderful proof of the value of electric energy that many more schemes have not been absolute failures.

The development of foreign business, then, depends almost entirely upon the financial position, and in many cases work has gone to our competitors, not because it was not offered or could not be obtained by us, but because our financiers and manufacturers declined to run the risk. Some months ago, for example, a man with a scheme was over in London from Iceland; no doubt this particular scheme has been considered by a number of firms in this country, but as yet no sign has been made that any one has accepted the offer. We should not be at all surprised to hear that the work is to be carried out by a foreign firm. This would merely show that English firms thought the risk too great, while their competitors accepted the risk. Of course, many such schemes are being constantly considered, and doubtless some which we consider bad have the elements of success in them, go to competitors, and help to swell the tide of their successes. On the whole, however, we think it better not to venture on these

Digitized by Google

risky speculations than to venture on the off-chance of its turning up trumps. We have thus briefly described the ordinary course of procedure. Where the Englishmen seem to fail in pioneer work is in waiting till promoters come to the financier or manufacturer, instead of the financier or manufacturer touting for themselves. It will be seen we assume financial aid to be all-important. When this is at the back of the manufacturer, the latter can afford to pick out the likely places for success by means of his own agents. Taking the case of Spain, one district of which we have previously referred to, some English firms, at any rate, are active in this market. Madrid has been more or less exploited, and according to our latest information there is to be a central station at Malaga which Messrs. Fowler and Co., of Leeds, will equip with the necessary plant, and the British Insulated Wire Company have the order to supply their H.T. lead-covered type of cable, which is to be laid in Doulton's conduits. Mr. Hammond is the consulting engineer, and Mr. Slater, lately at the Blackpool station, is engineer-in-charge. At the same time it may be mentioned that Messrs. Fowler and Co. are carrying out extensive works at Madrid. We mention these cases to show that work is being done in Spain, but whether this work comes within the category of that requiring financial aid or not we have no knowledge. It is quite certain, however, that, given financial aid, work will not be difficult to find, and it seems to us that the formation of such companies as the Electrical Development, just announced, is a move in the right direction, if great care is taken to finance only those schemes which have been carefully considered and present the minimum of risk.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ARC LAMPS.

SIR,—A contemporary having made a statement to the effect that Brockie-Pell Arc Lamp, Limited, has been formed for the purpose of taking over part of our business, we shall be glad if, by the courtesy of the editor of the *Electrical Engineer*, we are allowed to inform our customers and friends that the company referred to leaves our business alone, taking over from us only Messrs. Brockie and Pell, in whom we cannot claim to have proprietary rights. The company, we understand, has been formed for the exploitation of certain of Mr. Brockie's patents for which we did not see our way to make an offer, but our name did not appear in the prospectus. We have no interest in the concern, nor do we consider that our business in arc lamps will be adversely affected by it. We shall continue to manufacture our lamps as before, bestowing upon them that care in make and finish to which their great success in the past has been due. It may be difficult for experts to detect the difference between our lamp and that known up to the present as the "Brockie-Pell," but to our customers the difference will be apparent, inasmuch as the price of ours will now be reduced by the amount hitherto paid in royalties.—Yours, etc., JOHNSON AND PHILLIPS.

Egyptian Electric Tramway.—The electric tramway in Cairo, the first constructed in Egypt, has just been successfully inaugurated by a trial trip in the presence of Fahkry Pasha, Minister of Public Works, and a large number of spectators.

THE MISTAKES THAT MAY BE MADE IN CONSEQUENCE OF THE PREVAILING TENDENCY TO REDUCE THE SPEED OF ELECTRICAL MACHINERY.*

BY WILLIAM BAXTER, JUN.

Within the last two or three years the tendency to reduce the speed of electrical machinery has been growing so fast that it is desirable that the subject should be considered from various standpoints and the idea determined whether there is not such a thing as going too far in this direction. It is very important to know how long high-speed machinery will last, or at least what is its relative life compared with the slow-speed types. If the life of the former is but a few years, the slow-speed is undoubtedly better; on the other hand, if the high-speed type will last for many years, the case is quite different. Past experience seems to show that high speed in electrical machinery is not very destructive. There are very many high-speed dynamos in use to-day which have been in constant service for over 15 years, and are apparently in good condition. Many of these machines have solid bearings, but notwithstanding this the original bushings are in many cases still in use. The commutators have worn out and some have been replaced several times, but since the introduction of carbon brushes, wear, in this respect, has been reduced to a minimum, and unless there is considerable sparking, the commutator should now last almost indefinitely. The speed of what are considered high-speed engines is very low when compared with that of dynamos connected directly to steam turbines, yet the wear on these machines does not appear to be serious. Owing to the fact that electrical machines have but one moving part, and that the motion of this is rotary, high speeds are not likely to produce serious results unless the moving part is not properly balanced, a condition, however, seldom or never met with in machines turned out by any first-class manufacturers. A speed of 700 revolutions per minute would not bring any undue strain on a 100-kilowatt generator designed for a speed of 250 if direct connected. With this latter type of generator slow speed is desirable, in fact, necessary, on account of the limited speed of the engine. Engines of the size used for this purpose run at piston speeds ranging from 500ft. to 600ft. per minute, and the driving pulley is generally of a diameter about five times as great as the stroke. The belt velocity under such conditions is $5 \pi S \div 2$, S being the piston speed in feet per minute. Assuming a 100-kilowatt generator to be driven by such an engine running at a piston velocity of 600ft., the belt speed would be 4,710ft. per minute. This velocity would reduce the belt strain to about 1,000lb., which could be transmitted with a 14in. double belt. The speed of the generator would be about 500 revolutions per minute with a 3ft. pulley, and 600 by reducing the pulley to 30in. This would be a decided improvement on the results obtained with a speed, say, of 350 revolutions per minute, as the width of the belt would be reduced from 20 required for such a velocity to 14in., and the cost of the generator would be considerably less. There can be no question but what direct connection is the best for large units, say, from 200 kilowatts up, for with machines of that size the belts required to transmit the energy are so large as to be troublesome as well as costly, but it is not by any means certain that any advantage can be shown by direct-connected units of half this capacity. Many are willing to pay for compactness and simplicity, and such will use direct-connected generators, whether they possess any other advantages or not. But many others look wholly to the economical side of the case, and use that type of machine which will give the best results for the money invested. A direct-connected generator economises space, saves the expense of belt renewals, offers less danger, and is perhaps a more durable machine; but, after all, compactness is the only real advantage so far as small and medium-sized machines are concerned. The operation of belt generators shows that in the matter of durability they are all that can be desired. The wear and tear is not great, and it is very doubtful whether it will exceed 2 per cent. a year, including the

* From the *Electrical World* (New York).

Digitized by Google

renewal of belts, excluding the uncertain item of armature burn-outs, which is just as likely to occur with direct-connected as belt generators. If the ordinary repairs of belt machines can be made for an amount not to exceed 2 per cent., it seems evident that the direct-connected generator will not be able to show much gain in the cost of maintenance. In certain lines of work where the changes in load are frequent and very violent, the wear and tear on a direct-connected machine is much greater than on a belted one. This is especially the case in railway work, where it is not an uncommon thing for generators to become short-circuited. In the former, the elasticity of the belt relieves to a certain extent the sudden jar, but with the latter, as there is a rigid connection between the armature and the engine, the strain is transmitted instantly and sometimes with serious results. In the matter of efficiency the smaller sizes of direct-connected generators are not equal to the belted machines as the speed is so much reduced the efficiency must be sacrificed in order to keep the cost of production within reasonable limits. In many cases the space is limited and a direct-connected machine is the only kind that can be used. The speed of belted machines when driven from a belt shaft may be made anything desired. In such cases a speed should be adopted which will give belt velocities ranging from 4,000ft. per minute for machines of 20 or 25 kilowatts to about 6,000ft. per minute for units of 75 or 100 kilowatts. With these velocities the width and cost of belts can be kept within reasonable limits, and the wear will not be excessive, as will be demonstrated by actual experience. Generators belted directly to the driving engine must conform to the velocity of the latter, and the size of the driving wheel, and therefore will not be able to run in most cases as fast as if driven from a line shaft. The desire to reduce the speed has not been confined to generators, but has also affected motors, and it may be said with very beneficial results, as in most cases these machines were formerly run at velocities much higher than were advantageous. As motors are used to impart motion to other machinery, their speed should conform to the requirements of the latter. Motors of small sizes—say, from 1 h.p. to 4 h.p or 5 h.p.—generally operate high or moderately high speed machinery, and the shafting usually is run at velocities ranging from to 250 to 350 revolutions per minute. As it is desirable to avoid the use of an intermediate shaft whenever possible, the speed of the motor should be low enough to belt direct to the line shaft. This can be accomplished in almost every case by adopting speeds ranging, say, from 1,400 for 1 h.p. to 1,200 for 5 h.p. A 4in. pulley on the 1-h.p. motor belted to a 16in. pulley on the line shaft would be in good proportion, and would give the latter a velocity of 350 revolutions per minute. As the belt speed would be nearly 1,500ft. per minute, a 1in. belt would be more than ample to transmit the energy, and a 2in., which is the size that would probably be used, would run with an exceedingly light strain. The speed of the shafting does not as a rule drop below 200 revolutions per minute in the operation of the general run of machinery, even when the power used is as high as 100 or more horse-power; therefore it is not necessary to reduce the speed of motors above 5 h.p. much below 1,000 revolutions. For example, a 10-h.p. motor running at 1,000 revolution per minute by a reduction of 5 to 1 would be belted direct to a line shaft running at 200. This reduction would be obtained by using an 8in. pulley on the motor and a 40in. pulley on the shaft. The belt speed would be 2,000ft. per minute, therefore a 4in. or 5in. belt would transmit the power. A 30-h.p. motor, running at a velocity of 900, would have to reduce in the ratio of 4½ to 1, giving the line shaft a speed of 200. This would be obtained by using a 14in. pulley on the motor and 63in. on the shaft. The belt speed would be about 3,300ft. per minute, which would call for a 7in. or 8in. belt. The highest speed that can be used with motors if they are designed to belt direct to the line shaft without losing too large a pulley on the latter would be found to be very moderate and much under that at which they could be run without injurious results. Nevertheless it is much better to adopt this low speed. A higher velocity would reduce the cost of the motor, and as a result the cost of the repairs thereon. But this gain could only be effected by using an intermediate shaft, and the cost of this would undoubtedly be greater than the saving in the price of the motor; furthermore, there would be two belts to wear out instead of one. It is evident, therefore, that nothing could be saved by running the motor at a higher speed, and much would be lost in the way of simplicity and compactness. It may be said, however, that while it is desirable to use just as high a speed as the conditions will permit of, so as to reduce the first cost as well as the maintenance it is not wise to use a speed so great that the motor cannot be belted directly to the line shaft, unless the case is one where the speed of shafting is so low as to render direct belting impracticable. Most of the prominent motor manufacturers are now making machines for three different speeds—that is, high, moderate, and slow; consequently, a speed to meet the requirements of almost any case can be easily obtained, if the purchaser in making a selection is guided by good judgment.

A NEW ELECTROLYTIC GENERATOR FOR OXYGEN AND HYDROGEN.

BY W. S. FRANKLIN.

During the year 1895 a preliminary test* of a generator, of novel design, for the rapid and efficient generation of oxygen and hydrogen by electrolysis has been carried out in the physical laboratory of Iowa Agricultural College. The earlier part of this test brought out, as was to be expected, a number of essential imperfections in the preliminary design, which was accordingly modified and the apparatus twice reconstructed. The experimental work was unexpectedly cut short in October, 1895, before the finally constructed generator was fully tested. The final design and the more important results of the preliminary tests are here given. The work is to be continued during 1896.

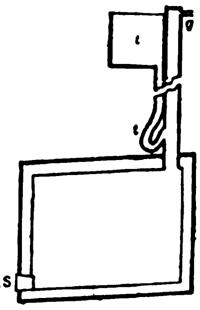

Fig. 1.

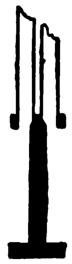

Fig. 2.

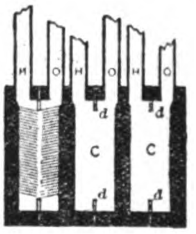

Fig. 3.

The generator consists of a number of massive frames cast of an alloy of 25 parts lead and 1 part antimony. The side view of one of these frames is shown in Fig. 1, and a sectional view in Fig. 2. These frames are bolted together, as shown in Fig. 3, the frames being separated by insulated diaphragms, *d d*, of gum rubber sheet of the kind used for steam packing. The central portions of these diaphragms are cut out as shown in Fig. 4. Two tall lead pipes and one reservoir and trap, *t t*, are fixed to each frame, as shown in Figs. 1 and 2. The watertight compartments, *c c* (Fig. 3), filled with dilute sulphuric acid (sp. gr., 1·17), are broken up by a number of thin glass strips, supported at the ends in hard rubber posts (Fig. 5). These glass strips, shown only in one compartment in Fig. 3, prevent the mixing of the two gases. The electric current enters the apparatus at one end frame and leaves it at the other. The gases collect in the tall lead pipes, pass out through glass tubes attached at *g* (Fig. 1), and are conducted to lead pipes leading to the gasholders. An opening, S (Fig. 1), two in each frame, closed with a rubber stopper, permits of the easy emptying and rinsing of the compartments. The generator is so supported that a vessel may be placed under these openings. The generator in the physical laboratory at Ames, now partly finished, is arranged in batteries of five cells each. Each

* By Messrs. C. R. Cave and D. M. Hosford. Thesis for 1895. MS. in the College Library, Ames, Iowa.

Digitized by Google

battery weighs about 300lb. The lead frames are 25·5 × 20·4 × 8cm outside dimensions, the metal is 1·8cm. thick, and the other dimensions are shown in the figures. The openings in the rubber diaphragms are 13cm. by 19cm. Such a battery of five cells will stand a continued current of considerably more than 22·5 amperes, without overheating, requiring about 3·8 volts of E.M.F. per cell. The gases produced are not perceptibly mixed.*

In the preliminary tests a battery of five cells of the above dimensions was used. The holes in the diaphragms were only 7·5cm. by 15·2cm., and no glass strips were used to prevent mixing of gases.

With this battery, the E.M.F. per cell, the final temperature rise above room temperature, and the purity of the gases were determined for currents ranging from 5·9 amperes to 22·5 amperes. The results are exhibited in the following table:

Number of run.	Current (amperes).	E.M.F. per cell (volts).	Temp. rise (centigrade)	Purity of H (per cent.)	Purity of O (per cent.)
1	5 9	3·0	2°·5	91 6	75 0
2	7·6	3·0	2° 0	92 7	78·2
3	8·8	3 2	6°·5	93·9	83·0
4	11·2	3·4	13°·5	94·4	83 2
5	13·6	3·5	15°·5	94·8	85·0
6	17·3	3·6	16°·5	94·8	85·0
7	20·0	3·7	21°·8	94·8	85·5
8	22 5	3·8	24°·0	94 7	86·2

The diaphragms for the first battery of five cells which was set up were made of best quality hard rubber sheet 1·5mm. thick. After about a month these diaphragms were found to be very badly broken. The battery was then reconstructed, using gum rubber sheet 1·5mm. thick, as mentioned above.

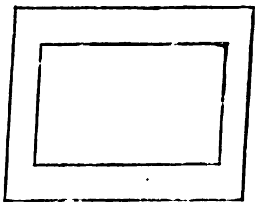

Fig. 4.

Fig. 5.

The efficiency of a hydrogen and oxygen generator requiring E volts per cell is calculated as follows: During the passage of one coulomb of electricity E Q joules of energy are expended, and ·00001039 Q grammes of hydrogen, and a corresponding quantity of oxygen are generated. The recombination of this H and O would give 34,200 × 4 2 × ·00001039 × Q joules, 34,200 gramme-calories of heat being generated by the combustion of one gramme of hydrogen in oxygen, and one gramme-calorie being equal to 4·2 joules. The efficiency is therefore $\eta = 34{,}200 \times 4{\cdot}2 \times {\cdot}00001039 \times Q \div E\,Q$, or

$$\eta = \frac{1{\cdot}45}{E}.$$

Therefore a cell used under such conditions as to require 3·8 volts has an efficiency of 38·2 per cent. The generator described† by E. L. Nichols and G. S. Moler required, under the conditions of their test, 19 volts per cell, the current through each cell being 24·6 amperes. The great efficiency of the generator here described is due to its low resistance; the anodes and cathodes have each 500qcm. area, and the distance between them is 6cm.

One great advantage of a low E.M.F. is that it is impossible for gas to be generated upon the detached sediment of PbO_2, which is gradually formed in the cell. The rapidity of formation of this sediment is, however, not great enough to seriously limit the life of the generator; for during the passage of 1,240 ampere-hours through the generator which was tested the amount of PbB_2 formed was not great enough to be estimated. The test was continued at frequent intervals for more than a month, so that it seems that no serious corrosion of the frames could take place in less than 15 or 20 years of use.

At 15 cents per kilowatt-hour for electrical energy, 660 litres H and 330 litres O would cost about 80 cents, counting four volts per cell of generator. This is sufficient to run a strong limelight for three hours. Counting oxygen only as of value, its cost would be 2·40dol. per kilolitre (about 8 cents per cubic foot). It seems, therefore, with a generator efficiency of 1·45 ÷ 4 = 36 per cent., that the electrolytic generation of H and O for laboratory purposes is not only the most convenient, but perhaps also the cheapest method of production.—*Journal of the Franklin Institute.*

* This point alone has been tested with the finally constructed apparatus. The estimates as to heating and required E.M.F. are based upon the preliminary tests. See below.

† *Physical Review*, vol. i., p. 373.

SOME FAULTS IN ARC-LAMP CARBONS.*

BY W. M. STINE.

There are some features of applied electrics which seem to remain in a condition of arrested development, and share to but a limited extent in the scientific progress made in so many lines. The reference here made is to the arc lamp, and arc-lamp carbons in particular. Regarding the latter, American consumers are content to import the better grades of carbons, while our own makers are unable to supply a competing article. These remarks are made not so much in the spirit of condemnation of existing conditions as in the hope that attention may be attracted to needed remedies.

A series of tests recently conducted by the writer may be offered in illustration. It had been noted that a certain make of carbons gave poor service when burned in one type of arc lamp, but were satisfactory when used with a number of other lamps. Those who have had much experience with constant-potential arc lighting know how frequently such conditions obtain. In order to arrive at an explanation of the facts the tests given below were carried out. They apply to constant potential service in particular.

The carbons were imported, of medium hardness, $\frac{11}{16}$in. in diameter, and cored for the positives and paired with smaller and solid negatives. The faults developed in use were the formation on both tips, but especially on the positive, of small globules. In action these seemed to bridge the arcs, thus short-circuiting the carbons and causing them to "stick." When cooled, the globules were found to be of two kinds; some were dark grey or metallic in appearance, others resembled jet, while all were of such high resistance that a magneto could not be rung through them. The grey globules were of such hardness that they readily scratched glass, and probably consisted in part of silicon carbide. The others seemed to have been formed from residual uncarbonised pitch. Another peculiarity of these carbons was that the usual white coating was very pronounced, extending to a height of several inches above the positive tip, and in some cases was nearly $\frac{1}{16}$in. in thickness. The white fumes had in time penetrated the lamp-case and fouled the works.

The lamps on which these faults were so apparent were of the differential type, and the carbons actuated by a clutch operated conjointly by the series and shunt magnets. Aside from the unsteadiness of the carbon feed usually found associated with the clutch feed in constant-potential circuits, the armature to the shunt coil was long, and ended in a large mass of laminated iron. The great mass and movement of the armature caused it to act somewhat like a heavy hammer, and being actuated by a magnet sensitive to every change in potential distribution in its own and mated arc was in constant motion.

Upon first consideration the faults above noted were attributed to the carbons alone, for it was not so apparent that the lamps were an important factor in producing them. Upon a further investigation it was found that the same carbons were burning with satisfaction in a variety of lamps on similar circuits, developing no unusual faults.

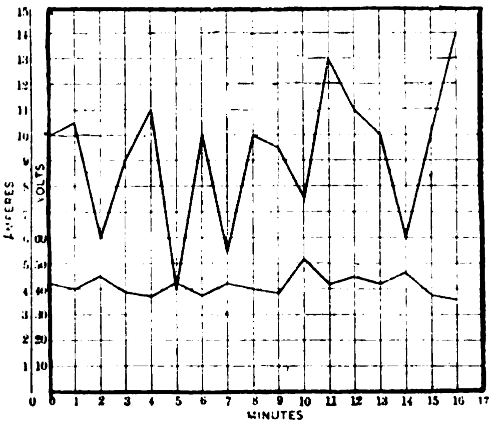
The Tests.—After burning a sufficient number of carbons, to ascertain the frequency with which the faults appeared, readings were taken and plotted as in the figure. Then, in order to further study the lamps, carbons of a variety

* From the *Electrical World* (New York).

Digitized by Google

of grades were burned and the readings plotted for comparison. The curves showed sufficient similarity to indicate that the lamps acted about the same, independent of the quality of the carbons. With harder grades of carbons no globules nor excessive coating formed. The source of the globules and coating was next sought. Surmising that they came principally from the material in the core, this was bored out. When burned, the coreless carbon, though much lowered in candle-power, showed but a slight coating and no globules formed.

A comparative study of the behaviour of the carbons when burned in a different type of lamp was next undertaken. The readings when plotted showed the present lamps were taking about the same average current as the others, but the regulation was more gradual, the extreme peaks of current being noticeably absent. The results obtained were a relatively higher candle-power, but slight coating and entire absence of globular formations. It was considered important to study the carbons when burning with practically constant currents. To effect this the carbons were clamped in a fixed position and fed by hand. The currents employed ranged from 10 to 50 amperes. In all cases the carbons showed nothing abnormal, for at a constant temperature due to fixed currents all the products of their combustion vaporised. The grain of the carbon was also tested. This was effected by reducing the carbons by electrolysis, a method already described by the writer. The grain was found to be very fine and practically uniform throughout. The white deposit on chemical analysis showed no unusual constituents, but was largely composed of silicic oxide. The cooled surface of a burned carbon generally showed the presence of a considerable amount of ferric oxide, though by no means an unusual percentage.



Test Curve of Arc Lamp Carbons.

Conclusions.—The opinion seems to be well founded that the faulty behaviour of the carbons was not due to unusual defects either in their composition or manufacture, but rather to the poor regulation of the lamps in which they were burned. On starting these lamps would usually take 29 amperes, while the curve in the figure shows a variation between four and fourteen amperes. Moreover, these variations were both extremely abrupt and frequent. The evidence of the tests just detailed indicated that during the peaks of current the high temperature drove out the uncarbonised pitch, especially from the core, and that the plastic carbon fused with the silicic and ferric oxide impurities. These were followed by a sudden dropping of the current to very low values, cooling the carbons, preventing these substances from volatilising, and passing to the edge of the crater they there assumed permanent form. At times when such globules attained a larger size, they caught the carbons when in near approach and so produced the "sticking" of the arc. When these carbons were burned with a fairly uniform current, the extraneous compounds formed more gradually and were slowly dissipated.

For constant-potential arc lighting it is advisable to use carbons of medium softness for high candle-power, and they must—at least at the present stage of carbon manufacture—be cored.

To those who are constantly testing carbons, it seems that their quality should be greatly improved. Perhaps the manufacturers take a different view, because they do not find improvement either possible or profitable. The ideal carbon should be free from both iron and silicon, and the binding pitch in it should be thoroughly carbonised. The difficulty at present seems to be to prevent the carbons becoming graphitic when so thoroughly carbonised. The difficulty is increased by the use of softer cores, in which a higher percentage of pitch and often alkaline carbonates are employed.

As to the methods of regulation of constant-potential arc lamps, a decided difference of both opinion and practice exists. Some hold that such lamps should be differentially wound, others that only series regulation is efficient. The objection to the use of a shunt coil is that its action is subject to every change in the potential distribution throughout the series of arcs and resistances. The method of feed is perhaps of even greater importance. The feed should be positive, with no retrograde movement except a "take-up" for striking the arc. Any form of clutch which is operated through all the changes of magnetism of the regulating magnet must inevitably produce a continually changing arc. No manufacturer can produce a carbon for high candle-power that will yield satisfactory results with such mechanism. Only very hard carbons should be used in such lamps, the resulting low candle-power being unavoidable.

ALTERNATE-CURRENT TRANSFORMERS.*

BY DR. J. A. FLEMING, F.R.S.

LECTURE III.

The Testing of Transformers.

Having considered the action and construction of transformers, our next duty is to notice the principal facts connected with the testing of transformers. This is a matter of considerable importance. It is not too much to say that in very few alternating-current stations is there any proper system of purchasing transformers to a rigid specification, and enforcing delivery to this specification by efficient methods of electrical testing. Engineers appear to be far too often quite content to accept manufacturers' figures without any confirmation. As an instance of the possible consequences of such a course I may mention that not long ago I had occasion to specify for two transformers on behalf of a corporation; the core loss of these transformers was to be not greater than 550 watts when measured at the proper primary pressure, and on open secondary circuit. When the transformers were delivered they were tested. One of them was found to comply with the specification, the other took up 1,090 watts under the same circumstances. As these transformers were 30-kilowatt transformers, intended to be worked in a sub-station, and to be connected with the mains for at least 4,000 hours in the year, it is perfectly clear that if no test had been applied, and if the transformers had both been accepted, one of these transformers would have taken up 500 watts more than the other. This additional core loss, proceeding for 4,000 hours in the year, would have meant an addition to the magnetising losses of 2,000 Board of Trade units per annum. As this would have involved an expenditure in coal and water of at least one penny per unit, the facts, translated into money, mean that one transformer would cost something like £8 per annum more than the other to maintain magnetised. If this is capitalised at only 3 per cent. it means £240, whereas the actual cost of the transformers did not exceed £140 each. It is clear, therefore, that the omission of a systematic process of testing transformers and of specifying for them for test may involve a supply company or corporation in an increased annual expenditure for maintenance, which under some circumstances may even amount to a considerable sum. In dealing briefly with the subject of testing transformers I shall not attempt to describe all the many different methods which have been suggested, but confine myself shortly to one which is simple, direct, and can be applied in any sub-station or workshop. It should always be remembered that although an electrical method may theoretically give the required result, yet practically it may be difficult to get good results with it on account of the fact that to obtain the necessary accuracy we must assume an unattainable precision in some of the measurements. The method which, after long experience in this matter, I have found most applicable in ordinary cases is one depending on the employment of a properly constructed wattmeter, standard power absorbing resistance, and an auxiliary transformer. We will discuss, in the first place, the construction of each of these instruments separately. If an

alternating current is sent through a fixed coil of wire, and another current through a movable coil suspended with its magnetic axis at right angles to the first coil, the centres of the coils being coincident, then in general we find an electrodynamic force tending to turn the movable coil from one position to another. If the initial position of the coils is with their magnetic axes at right angles, then the passage of the current tends to displace the magnetic axes so as to make them coincident. If a couple or torque is applied to the movable coil to bring it back to its original position, either by means of a spiral spring or a torsion wire, it can be shown that the couple required to hold the coils in their initial position, with magnetic axes at right angles to one another, is proportional to the mean

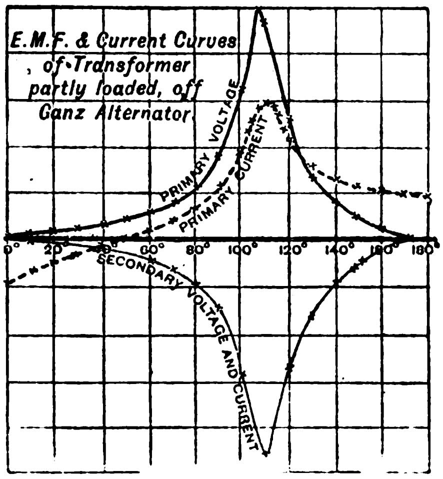

Fig. 34.

value of the product of the instantaneous valves of the two periodic currents passing through the two coils taken at equidistant intervals throughout one complete period. This mean product is therefore at once measured in terms of a mechanical couple. Such an arrangement is called an electro-dynamometer. If the current through one of these coils is the current being supplied to an inductive circuit, say, a transformer, and if the current through the other circuit, say, the movable circuit, can be made to be proportional to the potential difference between the extremities of the inductive circuit, then the dynamometer, now called a wattmeter, will give us when used as above described the true mean value of the product of the instantaneous values of the current through the inductive circuit and its terminal potential difference taken at equidistant intervals throughout the phase; this mean product is a measure of the mean power being taken up at that instant in the inductive

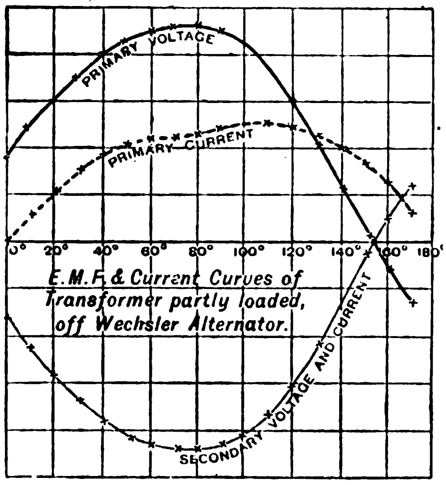

Fig. 35.

circuit, and hence we are able by one measurement to measure this power. In order that good results may be obtained with a wattmeter constructed as above described when employing alternating currents there are certain precautions which must be observed, but which instrument-makers almost habitually disregard. In the first place, the wattmeter must be constructed entirely of non-conducting material. There must be no metal, either iron or brass, in or near the fixed or movable coils. The reason for this is that if metal is placed in this position the alternating currents circulating in the fixed or movable coils set up eddy currents in this metal, and these eddy currents react upon the movable coil, and cause a displacement which creates a false reading. In the next place, in order to make the instrument direct reading it is essential that the fixed coil should be constructed in two parts which are capable of being moved to or from one another, so as to strengthen or weaken the field in the place where the movable coil hangs. In this manner the wattmeter can be adjusted so that a certain angular deflection of the torsion head of the instrument, creating a certain definite couple acting on the movable coil, can be made to mean a certain definite amount of mean power passing through the instrument. Thirdly, precautions must be taken to prevent the effect of the currents in the wires bringing the currents to or from the wattmeter affecting the movable coil. For this purpose these leads ought to be constructed of concentric cable, and the wattmeter carefully tested, before employment, to find out if this cause of error exists. In the next place, we require a non-inductive resistance to act as a standard power-absorber. This can best be made by employing the cages as described in the first lecture. A series of these inductionless resistances—say 20 of

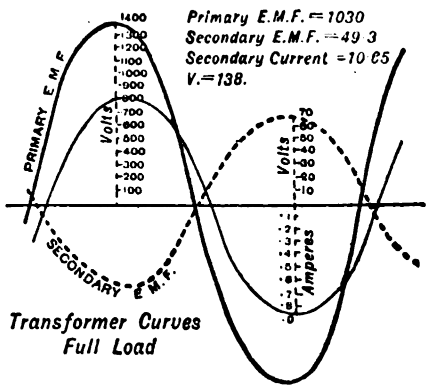

Fig. 36.

them—each capable of withstanding a pressure of 100 volts, are joined up in series, and well insulated. Under these circumstances a pressure of 2,000 volts can be placed on the extremities of this resistance, and a certain current will flow through it. This current can be measured by a sensitive dynamometer, which has previously been calibrated in the usual way. The potential difference between the extremities of the non-inductive resistance when employed on a high-tension circuit is best measured by means of an electrostatic voltmeter. Then lastly, we require an auxiliary transformer for the following purpose. It has been explained in Lecture I. that when a transformer of the closed iron circuit type is worked on a constant-potential primary circuit, the secondary E.M.F. set up in the secondary circuit is exactly opposite in phase to the primary E.M.F. This is further illustrated by the curves in Figs. 34, 35, 36, and 37, which show the primary and secondary E.M.F. curves of a Ganz, a Wechsler, and a Westinghouse transformer in various conditions of load, and it will be seen that the primary and secondary E.M.F. curves

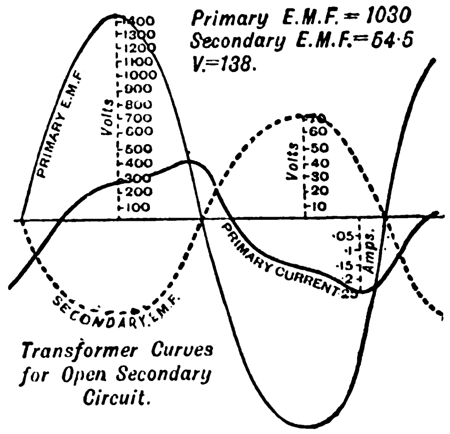

Fig. 37.

are in step with one another but opposite in phase. If, therefore, a transformer has its secondary circuit closed through a non-inductive resistance the secondary current will always be exactly opposite in phase, but proportional in magnitude to the potential difference between the primary terminals of the transformer. In order, then, to make a measurement of the efficiency of any transformer, this apparatus is arranged as as in Fig. 38; the transformer to be tested is denoted by the lines over the words, "Transformer under test." The wattmeter has its fixed coils connected in series with the primary circuit of the transformer to be tested, and its movable coil is connected in series with the secondary circuit of the transformer, which is called the auxiliary or wattmeter transformer, and by including a few incandescent lamps, L,

Digitized by Google

in the secondary circuit of this auxiliary transformer, the proper current can be given to the movable coil of the wattmeter. The primary circuit of the auxiliary transformer is connected to the same two mains as the primary circuit of the transformer to be tested, and an electrostatic voltmeter, V, is joined across the primary terminals of the transformer to be tested. The standard inductionless resistance just described is also placed across the primary terminals of the transformer to be tested, and a two-way high-tension switch is arranged so as to throw on the resistance or the primary circuit of the transformer under test at pleasure. A dynamometer is connected in series with this standard resistance to measure the current passing through it. The process of measuring the power supplied to the transformer under test is then as follows: In the first place, we connect to the wattmeter the standard power of absorbing resistance, and observe the current flowing through it, and the potential difference between its extremities. The product of these two numbers in amperes and volts gives us the mean power in watts taken up in the standard resistance. At the same instant a reading of the wattmeter is taken—that is to say, an observation of the amount of torsion required to be given to the wire or spring holding the movable coil to bring it back into its normal position. Let this reading be D_1, and let the power taken up in the standard resistance in watts be represented by W_1. In the next place, the standard resistance is switched off, and the transformer under test is switched on to the wattmeter, and another reading is taken of the wattmeter. Let this reading be D_2. The true power being taken up in this transformer under test is given by the value of the expression $\frac{D_2}{D_1} \times W_1$. In this manner the wattmeter is employed as a kind of electrical steelyard to weigh or measure the ratio between the known power taken up in the standard resistance and the unknown power taken up in the transformer.

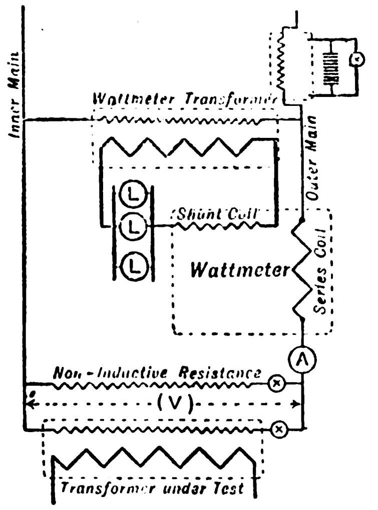

FIG. 38.

A measurement can thus be made with extreme accuracy either in a central station, a transformer sub-station, or a private house. All that it is necessary to do is to connect the wattmeter, in the manner described, in place of one of the primary fuses; that is, to place the series coil of the wattmeter in series with the transformer under test, and then to connect up the standard resistance and the auxiliary transformer, as shown in the diagram. The iron core loss of a transformer on open secondary circuit can thus be quickly and accurately measured, and with a properly-constructed wattmeter of the kind described there is not the slightest difficulty in making the measurement of the core loss of any required degree of accuracy.

The wattmeter before you and the standard resistances have in this way been used for an extensive series of measurements on the efficiency and core losses of the transformers of the City of London Electric Lighting Company. No difficulty was found in making these measurements, even in the small underground sub-stations which are distributed about the City. In addition to the iron core loss of the transformer on open secondary circuit it is also necessary to make two other measurements; one of these is the copper resistance of the two circuits of the transformer when the transformer is warm. The most easy method of doing this is by means of the fall of potential method. When the resistance of the primary circuit is moderately high, say anything over five ohms, it can be very easily measured on the ordinary Post Office Wheatstone bridge, taking the precaution, however, to short-circuit the secondary circuit, but in those cases in which the resistance of either or both circuits is very low then it is best measured in the following manner. A suitable standard low resistance, either 1-100th or 1-10th of an ohm, or one ohm is connected in series with the transformer circuit to be measured, and a small current from a dry cell or secondary battery is sent through this circuit, appropriate resistance being added to increase the total resistance to a proper amount. A movable coil high-resistance galvanometer has its terminals then connected first to the extremities of the standard low resistance, and second to the terminals of the copper circuit of the transformer which is under test. The ratio of these two deflections gives us at once the ratio of the resistance of the transformer circuit to that of the standard low resistance, and in this manner the copper resistance of each circuit of the transformer can be measured. This copper resistance, however, if measured at the ordinary temperature of the air has to be corrected to determine what it is when the transformer has reached its constant temperature. When a transformer is put to work, whether on open circuit or closed secondary circuit, it soon reaches a final temperature which ought never, under any circumstances, to be more than 100deg. C. In order to determine what this temperature is, one of the easiest methods is to connect the transformer on open secondary circuit for five or six hours to the high-pressure circuits, and when the transformer has reached its final and constant temperature to suddenly switch it off, and quickly make a measurement of the copper resistance of the secondary circuit as above described. Then, when the transformer is quite cold, another measurement of the copper resistance may be taken, which will be found to be much less; since the high-conductivity copper employed in transformer manufacture has a temperature coefficient of about 0·4 per cent. per degree C., it is very easy to calculate from these two measurements what is the final and constant temperature of the transformer. Having then measured the copper resistance, and calculated what it will be at the final temperature of the transformer, we have next to measure the secondary drop between full and no load. For this purpose an electrostatic voltmeter is connected across the secondary circuits, and its reading taken when the primary terminal potential difference is also known. The transformer is then loaded up to its full load on its secondary side, and the primary potential difference being kept at the same amount, the secondary potential difference will be found to have fallen, and the amount of difference between its value when the transformer is fully loaded and its value when the

Diagram of Connections for measuring the Drop in Volts of a Transformer.

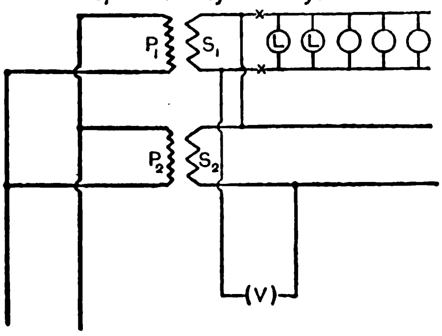

FIG. 39.

transformer is on open circuit is called the secondary drop. It is sometimes difficult to make this measurement with great accuracy, especially when the transformers are working off commercial circuits, but it can always be done in the way shown in the diagram in Fig. 39, if we possess two identical transformers and a low-reading electrostatic voltmeter. The two transformers are connected up with their primary circuits in parallel, and with their secondary circuits opposed to one another through the voltmeter. The voltmeter then reads, not secondary volts to either transformer, but the difference between the two differences. If one transformer is loaded up to full load, the voltmeter will read directly the secondary drop, and since both transformers are affected equally by any variation of the primary pressure, it does not affect their difference, and, therefore, there is no difficulty in getting the measurement with any required degree of accuracy. Having in this manner measured the iron core loss at no load, or on open secondary circuit, the copper resistances when the transformer is warm, and the secondary drop, we have all the information necessary to enable us to make a complete report on the transformer. It has been abundantly shown by experiments which were carried out by me in the year 1892,* that when a transformer is gradually loaded up, the iron core loss is constant at all loads, and that it is only the copper losses that vary. Hence, if we know the iron core loss—that is to say, the loss due to eddy currents and hysteresis in the core when the transformer is on open secondary circuit, we have only to add to this loss the copper losses in the transformer—

* See "Experimental Researches on Alternate-Current Transformers," by J. A. Fleming. *Proceedings* of the Institution of Electrical Engineers, November, 1892.

Digitized by Google

that is, the energy losses due to the resistance of the copper circuits—in order to obtain the total power absorption in the transformer at any load. Let P_1 be the total power in watts given in a transformer on the primary circuit, and let P_2 be the total power in watts given out on the secondary circuit to some external resistances, such as lamps. Let I be the total iron losses in the transformer, and C the total copper losses: $P_1 = I + C + P_2$. Hence the difference between P_1 and P_2 is a quantity which can be calculated when we know I and know C, and the efficiency of the transformer is given by the ratio of P_2 to P_1, expressed as a percentage. The copper losses can be calculated with sufficient accuracy in the following manner. Let us suppose that the transformer under test is a 10-kilowatt transformer—that is to say, is constructed to permit 10,000

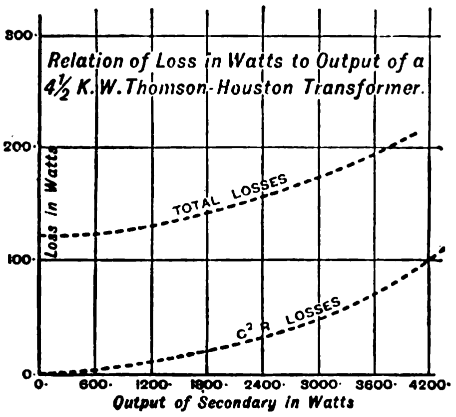

Fig. 40.

watts being taken out from the secondary circuit, and that the secondary watts are intended to be 100. Then the transformer at full load will give out a current of 100 amperes. If we imagine the full load of the transformer to be divided into 10 parts, then when the secondary circuit is delivering 10 amperes at 100 volts the transformer is on one-tenth load, when it is delivering 20 amperes at 100 volts the transformer is on two-tenths of full load, and so on. If the transformation ratio of the transformer is known—that is, the ratio between the secondary volts and the primary volts, or secondary terminal potential difference and primary terminal potential difference, when the transformer is on open secondary circuit—then the primary current can always be calculated with approximate accuracy from the secondary current by simply multiplying the secondary current by the number expressing the transformation ratio. Hence we can calculate the primary and secondary currents corresponding to each decimal fraction of full secondary

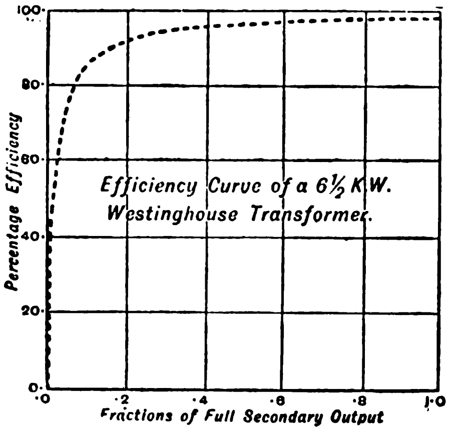

Fig. 41.

load. Knowing the resistances of the two circuits of the transformer when warm we can, therefore, calculate the copper losses in each circuit, because if R is the resistance of a circuit, and C the R.M.S. value of the current flowing through it, then C^2R is equal to the mean power wasted in that circuit. Calculating in this way the total copper losses for the two circuits corresponding to each decimal fraction of the full secondary load, we can add these values to the constant iron core loss experimentally determined, and obtain the total power lost in the transformer, corresponding to each decimal fraction of full load. We have, therefore, the difference between P_1 and P_2, corresponding to known values of P_2. Hence, we can calculate the ratio of P_1 to P_2 for each decimal fraction of the full secondary load, and, therefore, we have the efficiency of the transformer, and the total loss in the transformer given to us at each fraction of the full secondary load. This is by far the best method of determining the efficiency of very large transformers, because it does not necessitate loading up the transformer to its full load on an actual resistance; and even if this can be done the measurement which we actually require is the difference between two large observed quantities, and is, therefore, very liable to be affected by an error in either of them. Having obtained in this manner the total losses in the transformer for the various decimal fractions of the full secondary load, the most convenient graphic method of representing the results is by a total loss diagram. A horizontal line is taken, and is divided into 10 equal parts representing the decimal fractions of the full secondary load. At each part a vertical line is set up, representing the total losses in the transformer, both the copper and the iron losses, and two curves are drawn, as in Fig. 40, one representing the variation of the total copper losses in the transformer with the secondary load, and the other representing the constant iron loss at all loads. From this curve another curve, called the efficiency curve, can be drawn in the following manner (see Fig. 41). A horizontal line is taken representing the secondary output, and divided into 10 equal parts representing the decimal fractions of the full secondary load. At each point a vertical line is set up representing the ratio between the power given out by the transformer to the power taken in by the transformer, expressed as a percentage, and the curve delineated by these points gives us the efficiency curve of the transformer. In a well-designed transformer this efficiency curve is a square-shouldered curve, rising very rapidly up to 90 per cent. at one-tenth of full load, and to 96 or 97 per cent. at full load. A fairly good estimate of the value of a transformer, from an efficiency point of view, can be obtained by taking its efficiency at one-tenth of full secondary load. Even quite small transformers are now made which have an efficiency of 80 per cent. at one-tenth of full load. Large transformers of 30 to 50 kilowatts and upwards can be made to have an efficiency of 90 per cent. at one-tenth of full load. Ten years ago it was difficult to get any transformer having more than 40 to 50 per cent. of efficiency at one-tenth of full load.

It should be noted, however, that the form of this efficiency curve, as well as that of the current curve, depends upon the nature of the curve of primary E.M.F. The diagram in Fig. 30, Lecture II., shows the difference which may exist in the efficiency curves in the case of the same transformer tested in two different alternators, a Ganz and a Wechsler.

In considering the performance of transformers, we are not only concerned with the instantaneous efficiency—that is, the efficiency under any particular load—but with what is called the all-day or all-year efficiency. This can be calculated when we know the efficiency of the transformer at various loads, and when we know the nature of the load diagram, as it is called, on which the transformer is supplied. Thus, for instance, let us make the assumption that the load diagram of a transformer is a 10 per cent. load diagram—that is to say, let us assume that out of the 24 hours for 11 hours the transformer is giving no current from the secondary circuit, for five hours is supplying at one-tenth of its full secondary output, for four hours one-eighth, for three hours one-quarter, and for one hour three-quarters. It will be found, on adding up these outputs, that they amount to one-tenth of that which the transformer would be supplying if working at its full secondary output for the whole 24 hours. Let us take, then, the case of a 20-kilowatt transformer having 1·35 per cent. loss on open secondary circuit and 1·35 per cent. – 1·60 per cent. loss at full load. This gives an open circuit loss of 324 watts at no load—that is to say, 324 watts is the core loss in the transformer at no secondary load; the efficiency at one-tenth full load is 86 per cent., and at full load 96 per cent. From the total loss diagram it can then be shown that the transformer takes up in its primary circuit 324 watts on open secondary, 2,762 watts at one-tenth of full load, 3,372 watts at one-eighth of full load, 6,420 watts at one-fourth full load, and 18,162 at three-fourths of full load. We can then construct an energy balance-sheet for the transformers as follows, putting on one side the energy in watt-hours given by the primary circuit, and on the other side the energy in watt-hours taken from the secondary circuit, and these figures will be as follows:

Energy in Watt-hours given to Primary Circuit.

11 × 324 = 3,564
5 × 2,762 = 13,810
4 × 3,372 = 13,488
3 × 6,420 = 19,260
1 × 18,612 = 18,612
Total = 68,734 Board of Trade units.

Energy in Watt-hours taken from Secondary Circuit.

11 × 0 = 0
5 × 2,400 = 12,000
4 × 3,000 = 12,000
3 × 6,000 = 18,000
1 × 18,000 = 18,000
Total = 60,000 Board of Trade units.

Digitized by Google

It will be seen, therefore, that the total Board of Trade units given in the primary circuit in the 24 hours are 68,734, and the total Board of Trade units taken from the secondary circuit in 24 hours are 60,000. The secondary output is, therefore, 87 per cent. of the primary intake, and this is called the all-day efficiency of the transformer on that old diagram. It is not very far from the instantaneous or actual efficiency of the transformer at one-tenth of full load. It will generally be found that the actual efficiency at one-tenth of full load is a very fair guide to the all-day efficiency on a load having a load-factor of 10 per cent.

(To be continued.)

LEGAL INTELLIGENCE.

ELECTRICAL EXPERIMENTING.

At the Westminster County Court, on Tuesday, before his Honour Judge Lumley Smith, Q.C., the case of Holt *v.* Blenheim was heard.

The plaintiff, a dealer in electrical plant and machinery, sued the defendant to recover £6 in respect of four weeks' hire of a dynamo. It appeared that the defendant was desirous of carrying out some electric light experiments, and for that purpose he borrowed the dynamo from plaintiff. The defendant had made a payment in respect of a former hiring, and the present claim was in respect of additional hire over and above the specified time.

The defence was that the defendant was not personally liable, and machine was hired for a third party.

After hearing evidence at some length, his **Honour** said he was satisfied that the defendant was liable, and gave judgment for the sum claimed, with costs.

COMPANIES' MEETINGS AND REPORTS.

EDISON AND SWAN UNITED.

The thirteenth ordinary general meeting of the Edison and Swan United Electric Light Company, Limited, was held on Friday last at Cannon-street Hotel, E.C., Mr. James Staats Forbes (chairman of the Company) presiding.

The **Chairman**, in moving the adoption of the report, a copy of which appeared in our last week's issue, said it was necessary for him to be somewhat reticent regarding the business, for if he gave a great variety of details he would be only arming their opponents. Their business was progressing in bulk, although, under the necessity of competition, there was a diminution in the profit on many things. The year's working had given them a credit balance of £27,526, and, after providing the interest on the debentures—the price of the purchase of the Swan residuum—there was enough money to pay 5 per cent. on the A capital and to carry forward a considerable balance. They could pay a larger dividend than 5 per cent., only they did not think it would be prudent to do so in existing circumstances. They thought that 5 per cent. would be a very good dividend to maintain until they saw that they could safely pay more. As he had said, the competition had been and was severe, although it was a little less serious now. The Edison and Swan lamp had a certain reputation, and a great many were committed to use it, but some of them were naturally tempted by the offer of lamps—one lamp was very much like another so far as external appearance went—at a lower price. However, lamps, like friends, could only be tested by experience, and those who tried those cheaper lamps soon gave them up and came back to the Ediswan ones. That was a process constantly going on. The competition in the price of fittings, etc., was very keen, and in lamps and fittings the bulk of their trade had been done. Then the cost of materials had gone against them ; the price of platinum, brass, and some other things had been higher. They had a strike also in the early part of the year, which disarranged their affairs. There were the usual consequences of a strike. Those who made it were a long time out of work and lost a lot of money. The strike opened the eyes of the Board to the necessity of finding some method of making themselves independent of the class of people who caused the strike. It was now done with, but it necessarily affected adversely the result of the year's working. That was about the whole story of the year. After recapitulating some of the items of the accounts the Chairman said the directors had enjoyed in the past the usual sweets of experience—early blunders and errors—but had been utilising the knowledge gained. They knew now what was the worst that could befall them in the future, and what they knew justified a strong belief that the Company might be made still more prosperous, and be in a position to increase its operations to an extent that would benefit the shareholders considerably. Mr. Swan, who was about the largest shareholder in the Company, had staked his reputation upon it by keeping a large fortune in the Company. Though a great scientist and inventor, he was at the same time an extremely good man of business, and he did not apprehend much danger of his property or his dividends diminishing in value. He (the Chairman) felt the same.

Mr. J. W. Swan seconded the resolution, which was carried unanimously.

The **Chairman** moved that a dividend be declared on the "A" shares of the Company at the rate of 5 per cent. per annum in respect of the six months ending June 30, 1896, making, with the interim dividend paid on February 18, 1896, 5 per cent. on the "A" share capital of the Company, as now paid up in respect of the year ending June 30, 1896.

Mr. Ernest Villiers seconded this.

Mr. K. Hedges, while congratulating the directors on the result of the year's trading, said that it had struck him that the lamp business was not so profitable as it might be. He thought the directors might do more than they did in the way of advertising their goods. As an electrical engineer, he was inundated with circulars from lamp manufacturers urging him to recommend their goods. In conclusion, he expressed surprise that the shares of the Company stood at so low a price in the market; at the present price they paid 10 per cent. to a purchaser of them.

The **Chairman**, in reply, said it was quite true that advertising oneself and one's wares was a very popular thing nowadays, but there were various ways of doing it. The Company relied on the fact that they produced a good lamp, and that people who made installations knew that it was so. As to other advertising, he would remind Mr. Hedges that in every London hotel and in every bedroom of those hotels advertisements of the Company's goods were to be found.

The resolution was then put, and carried unanimously.

The retiring directors, Major Flood Page and Mr. J. W. Swan, were re-elected, and Messrs. Welton, Jones, and Co. reappointed auditors.

WATERLOO AND CITY RAILWAY COMPANY.

The half-yearly general meeting of this Company was held at Waterloo Station yesterday (Thursday afternoon), Mr. Wyndham Portal presiding.

The directors' report stated that the arrangement with respect to the City terminus had been completed, and the necessary agreement executed between the Company and the Central London Railway Company.

The engineers, in their report, stated that the plans for the generating station were being prepared, and would be ready for letting the contract shortly after the holidays.

On the motion of the **Chairman**, the report was adopted.

NATIONAL TELEPHONE COMPANY, LIMITED.

The eighteenth ordinary general meeting of this Company was held on Thursday afternoon last at the Cannon-street Hotel, and a brief report appeared in our last issue, together with the directors' report and accounts.

Mr. J. S. Forbes (the chairman), in moving the adoption of these, said, as the report stated, a not inconsiderable outlay had been attributable to the substitution of metallic circuits for single lines, and the construction of underground works in lieu of overhead wires. Of this amount £45,000 had been expended in Manchester during the half-year, thus greatly improving the efficiency of the service for existing subscribers, and providing a large additional amount of capacity for increased business. When the system was in full work it should involve a much less annual charge for maintenance. In London also they were just entering upon some work of the same kind, which was wanted for the service of the Metropolis. He would like to repeat what he had said before, that the Company had to expend three years' subscriptions received from each subscriber before they touched a farthing of his money. This was a great risk, and he would make a present of the information to those who might be contemplating the establishment of competing businesses in London. They were spending money at a very rapid rate—last half-year £240,000, and a similar sum in the current half-year, making about half a million of money. The result showed that the capital account was in debt £210,000. The other side of the accounts showed that during the last half-year they had expended on lands, buildings, and machinery £44,850. They had spent that amount of the reserve fund, and altogether they had spent in Dublin, Leeds, London, Birmingham, Bradford, and Manchester a total amount up to the present time of £208,000 on land and buildings. The report dealt with the transfer of trunk lines to the State. In accordance with the agreement arrived at, these had been surrendered to the Post Office on April 4 last, in consideration, among other things, of the payment of their value as fixed by experts, after an elaborate and prolonged enquiry. The transfer had naturally involved some inconvenience in connection with the through telephone business of the country, but as the Post Office authorities and the Company's officers were loyally co-operating with the object of securing the most efficient possible service it was hoped that the inconvenience might be speedily terminated. In place of Sir Henry Calcraft, deceased, the Board had elected the Right Hon. Sir James Fergusson, who as Postmaster General, initiated the present telephone system. He need hardly point out the advantage of having the aid of such a director.

Lord Harris seconded the resolution.

There were some remarks from **Messrs. Galbraith, Hall, Leake,** and others, and

The **Chairman**, in reply, said that they had received the amount due to them for the trunk wires, and they were satisfied with the bargain they had made. With reference to the reserve fund, it was most important for the shareholders to remember that the Company would cease to have any life at the end of 16 years. They therefore had to bear in mind the possibility that their

Digitized by Google

values of so many-millions in the balance sheet might not be realisable at the end of the term. As to the amount of the dividend, if at the end of the current half-year they found that they could prudently pay a dividend of 6 per cent. they would do so. The proposed pension fund was based on a 15 years' tenure. The theory was that the Government would take over their employés with the telephone at the end of the Company's term, but their obligation in any case was limited to 15 years.

The resolution for the report and dividends was unanimously adopted, and the appointment of Sir J. Fergusson approved.

ELECTRIC CONSTRUCTION COMPANY, LIMITED.

Directors: Sir Daniel Cooper, Bart., G.C.M.G., chairman; James William Barclay, deputy chairman; Philip Edward Beachcroft; John Irving Courtenay; Sir Henry C. Mance, C.I.E.; James Pender, M.P. Manager: A. B. Blackburn, M.I.C.E. Secretary: James Gray.

Report of the directors to be submitted to the shareholders at the third annual general meeting of the Company to be held at Winchester House, Old Broad-street, London, E.C., on August 27, 1896, at 2 30 p.m.:

The net profit of the year, after paying interest and general expenses, providing for the full maintenance of buildings and plant, and appropriating £5,000 to depreciation account, is £16,450. 9s. 11d. Adding to this amount the credit balance of £10,134. 15s. 10d. from last year the sum available for dividend is £26,585. 5s. 9d., whereof the directors recommend that £2,288. 0s. 5d. be applied in payment of the dividend on the preference shares on September 1 next, and £11,000 in payment of a dividend of 5 per cent., free of income tax, on the ordinary shares, one-half on September 1 next and the other half on March 1, 1897, and that the balance, £13,297. 5s. 4d., be carried forward to the credit of next year. The gross manufacturing profit has increased from £31,814. 12s. 7d. in 1895 to £41,353. 1s. in 1896. The output of the works shows a considerable increase on that of the previous year, and the Company's high reputation for excellence in design and quality of workmanship has been fully maintained. The factories are now full of orders at fairly remunerative prices. To meet the demands of the growing business a considerable addition has been made to the buildings and plant at Bushbury, and these extensions, recently completed, will not only facilitate prompt execution of orders, but also tend to economy in production. Among the more important works completed during the year, or now in progress, may be mentioned orders from the War Office and Crown Agents for the Colonies, and plant for various central stations, including Shoreditch, Clerkenwell, Leyton, Durban, and the Hartlepools Electric Tramways. The directors who retire by rotation at the general meeting are Sir Henry Mance and Mr. Philip Edward Beachcroft. They are eligible for re-election. Messrs. James Meston and Co., the auditors for the past year, offer themselves for re election.

PROFIT AND LOSS ACCOUNT, YEAR ENDED JUNE 30, 1896.

Expenditure.				£	s.	d.

* Note.—There is a contingent liability in respect of amounts uncalled on certain of these shares.

CENTRAL LONDON RAILWAY COMPANY.

The report of the directors for the half-year ending June 30, 1896, states that the expenditure during the half-year has amounted to £273,812. 14s. 9d., which, added to the amount previously expended, makes a total outlay of £442,098. 0s. 11d. The further payments for property and works required during the next few months has rendered a call upon the shareholders necessary, and accordingly a call of £2 per share, payable on September 1 next, has been made. Representations have from time to time been made to the effect that it would be a convenience to proprietors desiring to do so if they could be allowed to pay up in full the uncalled capital on their shares in advance of calls, and the directors have decided, until further notice, to accept such payments in advance, and the necessary form of application can be obtained from the secretary. It will be seen from the report of the engineers that satisfactory progress has been made with the works. The contractors have now obtained possession of station sites at Shepherd's Bush, Holland-park, Notting Hill-gate, Westbourne, Marble Arch, Oxford-circus, Tottenham Court-road, British Museum, and Chancery-lane. It has been considered expedient to enlarge the Post Office Station in Newgate-street, and there will consequently be some delay in acquiring the additional property which will be required for that purpose. The Great Eastern Company has approved the plans prepared by the engineers for the station at Liverpool-street, and it is hoped that an agreement satisfactory to all parties may soon be completed. The North London Company has also approved plans providing for a public access from Broad street Station to the Liverpool-street Station of the Central London Company, and agreement is in course of preparation in connection therewith. The resolutions for the division, if thought fit, of the shares into "preferred half-shares" and "deferred half-shares," which will be submitted at an extraordinary general meeting to be held at the conclusion of the half-yearly meeting, are set out in the notice convening the meeting. The rate of interest payable on the capital from time to time paid up will not be affected by the proposed division, if adopted, so long as the line is in course of construction. The interest will remain during that time at the rate of 3 per cent. per annum, in accordance with the provisions of the Act of Parliament. The preference dividend of 4 per cent. proposed to be assigned to the "preferred half-shares" will not

Digitized by Google

come into force until the railway is completed and opened for traffic. The following is the clause in the Central London Act, 1891, relating to the division of shares: "Subject to the provisions of this Act the Company, with the authority of three-fourths of the votes of the shareholders present in person or by proxy at a general meeting of the Company specially convened for the purpose, may from time to time divide any share in their capital into half shares, of which one shall be called 'preferred half share,' and the other shall be called 'deferred half-share,' but the Company shall not so divide any share under the authority of this Act unless and until not less than 60 per cent. upon such share has been paid up, and upon every such division 50 per cent. upon the entire share shall be carried to the credit of the deferred half-share (being the whole amount payable thereon), and the residue to the credit of the preferred half-share." The report is signed by the chairman, Mr. Henry Tennant. The shareholders' meeting takes place at Cannon-street Hotel on August 11.

The engineers' report alluded to above is signed by Messrs. Fowler, Baker, and Greathead, and is as follows: We have to report that possession has now been obtained of the station sites, with the exception of Queen's-road, Davies street, and Newgate-street. The construction of the Bank Station has been commenced, and good progress has been made with the shafts at Shepherd's Bush and Chancery-lane stations. Satisfactory progress has been made with the preparation of the ironwork for the tunnels throughout the whole length of the line and of the shields and other appliances for the execution of this work.

IMPERIAL TRAMWAYS COMPANY, LIMITED.

The report of the directors of this Company for the half-year ended June 30 states that the receipts of the Corris Railway continue satisfactory, and the profit earned admits of a dividend of 5 per cent. per annum on the ordinary stock all of which is owned by the Imperial Company. The total receipts of the Middlesbrough Tramways amount to £3,303, and the expenditure £2,579, showing a profit of £724. The gross receipts of the Reading Company have been £3,566 whilst the expenditure was £2,803, the profit being £763, or sufficient for a dividend at the rate of 6¾ per cent. per annum on the capital. The directors have for some time past had in preparation proposals for the conversion of the Reading tramways into electric lines and concurrently extending the tramways into other parts of the town. These proposals will in due course be submitted to the Town Council for consideration and the necessary powers applied for. The directors recently informed the shareholders that they had succeeded in disposing of the Company's interest in the Dublin Southern District Tramways Company, and their estimate of £106,000 as the net purchase-money is approximately correct. A deposit of £30,000 has been received from the purchasers, and the balance of the purchase money is payable on or before December 31 next. The shares will only be transferred by the Company against receipt of the balance of purchase-money. The gross revenue, omitting all credit on Dublin account, amounts to £1,892 and the net profit to £1,695, adding to which the balance brought forward (£654. 11s. 4d.) a total of £2,349 is available Of this sum, £624 has been absorbed in debenture interest and the directors recommend the appropriation of the remainder as follows: to preference dividend at 6 per cent. per annum, £350; ordinary dividend at 2½ per cent. per annum, £1,333; and to carry forward £42. During the half-year £4,450 debentures were allotted, thus completing the whole issue. The shareholders' meeting takes place at Bristol on Saturday.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Odessa.—The Municipal Authorities will receive tenders up to August 13 for street electric lighting and for the lighting of the new prison.

Oldham.—The Corporation want tenders by 18th inst. for an electric feed-pump. Particulars from Mr. Andrew, Gas and Water Offices, Oldham.

Nava del Rey (Spain).—The Municipality are open to receive tenders up to August 28 for the electric lighting of Nava del Rey for a period of 20 years.

Bucharest.—Tenders are wanted by August 19 for the electric lighting of the Boulevard Coltea. Application should be made to the Mairie, at Bucharest.

Dortmund (Germany).—The Municipal Authorities of Dortmund want tenders by September 1 for engines, boilers, and dynamos for the electric lighting of the town.

Cassel (Germany).—Tenders are wanted by the Slaughter-house Committee for an electric lighting installation of 80 incandescent and 14 arc lamps. The date is August 15.

Paris.—Tenders are wanted by August 14 for erecting lightning conductors. The estimate is about £400, and application should be made to l'Assistance publique, avenue Victoria 3, Paris.

Vich (Spain).—The contract will be allotted by the municipal authorities of Vich on August 17 for the electric lighting of the town for 10 years from June, 1897. The annual payment proposed is about £800.

Hampstead.—Tenders are wanted for the supply and erection of 80 arc lamp columns about 19ft. high, for the Hampstead Vestry. Particulars are obtainable at the Vestry's Electric Department Offices, 57, Pratt-street, Camden Town, N.W., and tenders must be in by August 24.

Islington (London).—The Vestry require tenders for the enlargement of their central electric lighting station, Eden-grove, Holloway-road, N. Application should be made to Mr. Wm. F. Dewey, vestry clerk, Vestry Hall, Upper-street, Islington, N., with a deposit of £5, before August 10.

Halifax.—Firms desiring to tender for the electric lighting and hoists at the new infirmary to be built for the Guardians of the Halifax Union must apply before August 13 to the architects, Messrs. Horsfall and Williams, George-street and deposit two guineas with the Clerk to the Guardians, Union Offices, Halifax.

Dundee.—The Gas Commissioners invite tenders for the supply of indiarubber-covered cables for electric lighting in the Overgate, Wellgate, and Whitehall-street districts of the city. Particulars as to quantities, etc., can be had from the Electrical Engineer, Dudhope-crescent-road, Dundee. Tenders to the Clerk of the Commissioners, City Chambers, Dundee, by 19th inst.

Simla (India).—The Municipality is inviting tenders for lighting by electric light for a term of years the principal thoroughfares and buildings belonging to the Municipality. Tenders must be submitted by September 1 next. Should any proposal be accepted, the Municipality will afford the successful tenderer all facilities to extend the system of lighting to private houses.

Cologne.—Tenders are required by the Municipal Authorities for the construction and working of electric tramways in the city of Cologne to an aggregate length of 20·3 kilometres (12½ miles). Specifications, plans, and particulars are obtainable for 10 marks (10s.) from der Registrateur B, des Oberbürgermeisteramt, Köln, Germany, and tenders must be in by November 6.

Madras.—Tenders are invited for the lighting by electricity of Government House, Madras, including the banqueting-hall and aide-de-camps' bungalow, and also for the lighting of Government House, Guindy, including the military secretary's bungalow. For particulars application must be made to the consulting architect to the Government, Chepank, Madras. Tenders will be opened on November 11, 1896.

Radcliffe.—The District Council invite tenders for the supply and erection of a gas-engine and dynamo and the fitting up and lighting of the Technical School by electricity. A copy of the plans, sections, and specifications may be obtained on payment of 10s. 6d., and forms of tender obtained from the Surveyor, Council Offices, Radcliffe. Sealed and endorsed tenders to be sent to Mr. J. Sharples, clerk by 17th inst.

Voghera (Italy).—In view of the expiration of their contract with the local gas company in 1898, the municipal authorities of Voghera are desirous of receiving during the present year propositions for the lighting of the town either by the electric light or a mixed system of gas and electricity. The population is 16,000. Application should be made to L'Administrazione Comunale, Voghera, who will give all particulars necessary.

Mayaguez (Puerto Rico).—The Secretary of State for Foreign Affairs has been informed by H.M. Ambassador at Madrid that the Spanish Government have invited tenders for the construction and working of a telephone system in Mayagüez, Puerto Rico. The date fixed for the consideration of tenders is October 8, and such particulars as have been received may be inspected at the Commercial Department of the Foreign Office between the hours of 11 and 6 daily.

Mexico.—The municipal authorities of the city of Mexico are prepared to receive proposals for the street lighting by incandescent lamps for a period of eight years. Tenders should be sent in by August 31. The Secretary of State for Foreign Affairs has received from the British Consul at Mexico a pamphlet issued by the Municipal Council of the city containing particulars as to the tenders, and this may be seen on application to the Commercial Department of the Foreign Office between the hours of 11 and 6. The plan as laid out accounts for 480 arc lamps of 2,000 c.p. each, and 120 of 1 200 c p., to which are added 150 incandescent lamps.

Southampton.—The Harbour Board invite tenders for the construction and erection of four electric cranes and accessories, and also for alterations to a gantry of an existing crane, on the Town Quay, Southampton. Specification, with two general drawings attached, may be obtained on and after 20th inst. from Mr. A. H Skelton, clerk, Town Quay, Southampton, upon payment of £3. 3s, which will not be returned, and further detailed plans may be seen at the office of the electrical engineer, Mr. J. G. W. Aldridge, 9, Victoria-street, Westminster, S.W. Sealed tenders, marked "Tenders for Electric Cranes," should be sent to the clerk by August 31.

Manchester.—The Gas Committee require tenders for the construction of an underground electric lighting sub station in Piccadilly The general conditions of contract, bills of quantities, and forms of tender can be obtained on application in writing to Mr. C. Nickson, superintendent, Gas Department, Town Hall, Manchester. A deposit of £1. 1s., which will be returned on receipt of a bona fide tender, must accompany each application for a tender form. Sealed tenders, addressed to the Chairman of the Electric Light Sub-Committee, and endorsed "Tender for Underground Sub-Station," must be delivered at the Gas Office, Town Hall, by 10 a.m. on August 8.

Jassy.—The Mayoralty of the Town of Jassy (Roumania) has given notice that on August 23, 1896, old style (by our reckoning September 4), tenders will be received, for the second time, in the hall of the Municipal Council, for "the installation of a frigorific

Digitized by Google

hall, electric light, and various accessories requisite for new public slaughter-houses. Offers must be in accordance with the specification, the conditions of contract, the special conditions, and the plans deposited in the offices of the director of the slaughter house works, where particulars may be obtained." Tenders are to be enclosed in sealed envelopes, marked "Offre pour l'installation de la Hall Frigorifique," and senders of tenders must abide by articles 68-79 of the Roumanian Public Accounts Act. All tenders and supplementary documents must be in either the Roumanian or French language.

Bath.—The Corporation invite tenders for the supply and erection of the following plant:—Section A: Boiler and fittings, feed pump, etc. Section B: Steam alternators, oil-filter, fittings, etc., steam, exhaust, feed, blow-off, and sundry pipes, valves, etc. Section C: Mains. Section D: Crane. Section E: Arc lamps and posts. Tenderers are at liberty to tender for either section, but not for part of a section. The ground plan of plant and specification, with terms and conditions of tender and contract, may be obtained at the office of Mr. Robert Hammond, the consulting engineer, Ormond House, Great Trinity-lane, E.C., on and after the 13th inst., on payment of £2. 2s., which will be returned on receipt of a bona fide tender. Sealed tenders, marked "Tender for Electric Lighting," must be addressed to Mr. F. H. Moger, clerk, 3, Wood-street, Bath, and delivered by the 31st inst.

RESULTS OF TENDERS.

Bath.—The Baths Committee have accepted the tender of Messrs. Laing, Wharton, and Down, London, for the electric wiring of the Pump-room extension, at £273.

Wolverhampton.—The Town Council have decided to accept the tender of Messrs. Thomas Parker, Limited, for rewinding four armatures, altering magnets of transformers, and supplying starting resistances, at a total cost of £955. 10s.

Leeds.—The tender of Messrs. Laing, Wharton, and Down for trolley wire and attachments for the Roundhay and Kirkstall tramway, at the sum of £5,740, has been accepted by the Town Council. This tender is £120 more than that of Messrs. Siemens, which was withdrawn.

St. George's, Hanover-square (London).—The Vestry have accepted the tender of Messrs. Ridout and Co., of 124, Regent-street, at £39. 15s., for wiring and supplying fittings for the Pimlico road offices, subject to an alternative price being obtained for utilising the existing fittings in the Board-room.

Bolton.—The contract has been placed with Messrs. Drake and Gorham for the large extension of the electric lighting at Messrs. Tootal, Broadhurst, and Lees's Daubhill Mills. Messrs. Drake and Gorham have also been successful in obtaining the contract for the lighting of the works of Strine's Printing Company, in Derbyshire.

BUSINESS NOTES.

Direct Spanish Telegraph Company.—For the month of July the receipts were £1,950.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,608.

New Address.—Messrs. Hailey and Co. have removed from Sloane-street to Pentagon Works, 30 Pavilion-road, S.W.

Linesmen.—The Postal Telegraph Linesmen and Mechanics' Association of the United Kingdom have held their first meeting at Manchester.

Gisburn (Yorks).—A suggestion has been made locally to utilise water power near at hand for the purpose of lighting the village electrically.

Cuba Submarine Telegraph Company.—For the half-year ending June 30 the directors recommend a dividend at the rate of 8 per cent. per annum.

West India and Panama Telegraph Company.—For the half-month ended July 31 the receipts were £1,920, as against £1,866 for the corresponding period of 1895.

Sale.—The clerk has reported to the District Council that the order for the electric lighting of the district had received Royal assent, and was in possession of the Council.

Wolverhampton.—The Town Council have decided to apply to the Local Government Board for sanction to borrow £600 for the purchase of an additional transformer.

Ambulance Work.—The Liverpool Overhead Railway Ambulance Society had a tournament in the grounds of the Merchant Taylors' School, Crosby, on Saturday last.

Worcester.—A dedication service has been held for the Hope Jones electrical organ in the cathedral. A short description of this has already been given in these columns.

Plymouth.—The Electric Lighting Committee have adopted Mr. Rider's report and scheme for lighting and power supply, and recommend that £45,000 should be borrowed to carry it out.

Dublin.—A resident in Monkstown has written to the local Press complaining that the electric tramcars do not run so fast as they used to at first. He suggests fixed stopping points to save time

Bristol.—Colonel Marsh, R.E., one of the Local Government Board inspectors, has held an enquiry into the application of the Bristol Corporation to borrow £75,000 for electric lighting purposes.

Southwark (London).—The St. George's Vestry have agreed to the National Telephone Company laying their mains underground, on condition that the company pay a rental of £500 per annum to the parish.

Esh (Durham).—A committee meeting has been held to consider a proposal to light two of the wards of the parish—namely, Langley Park and Ushaw Moor—by electricity, and Quebec with improved oil lamps.

Mile End (London).—Notice has been given by the County of London and Brush Provincial Electric Lighting Company, Limited, of their intention to apply for a provisional order to light Mile End Old Town.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending Aug. 2 amounted to £1,357, as compared with £1,355 in the corresponding week of the previous year, being an increase of £2.

National Telephone Company.—The Right Hon. Sir James Fergusson, M P., has been elected a director of the National Telephone Company, Limited, to fill the vacancy caused by the death of Sir Henry George Calcraft.

Bristol Tramways and Carriage Company, Limited.—The traffic returns for the week ending July 31 were £2,376. 11s. 6d., compared with £1,985. 14s. 10d. for the corresponding period of last year, being an increase of £390. 16s. 8d.

Mosses and Mitchell.—Messrs. Mosses and Mitchell, of Chiswell-street, E.C., announce that Mr. C. Barry Hayes and Mr. John Wood, who for many years have taken a leading part in the management, have now become partners in the firm.

Competition—A competition has been announced for schemes for electric lighting and power transmission for the new prisons at Fresnes-les-Rungis. The competition takes place at the Hotel de Ville, Paris, and schemes must be in by October 1.

Brazil.—According to telegrams from Rio de Janeiro the contract for furnishing the plant for the electric lighting of Carangola, State of Rio de Janeiro, has been placed in Europe, but neither the name of the firm or its nationality is given.

Electric Light Fittings and Fire.—The Liverpool and London and Globe Insurance Company are issuing a pamphlet embodying electrical installation rules, with a view to avoiding the risks of fire which attach to ignorantly or carelessly applied fittings.

D P. Battery Company, Limited.—At the general meeting of the D.P. Battery Company a dividend of 19 per cent. has been declared for the past year. It has been determined, in view of the profits that have resulted, to lower the price of the battery.

Portsmouth.—The Electric Lighting Committee have instructed their engineer to get out specifications for additional electrical plant. The order for the vertical engine will be placed with Messrs. Yates and Thom, and Ferranti's alternators will be used.

Metal Manufacturers' Association.—At a meeting of the committee of the Metal Manufacturers' Association it has been decided to advance the prices of rolled brass and copper, brazed brass tubes, and brass and copper wire ½d. per pound, from August 1.

City and South London Railway.—The returns for the week ended August 2 were £1,036, compared with £804 for the corresponding period of last year, being an increase of £232 The total receipts for the half-year 1896 were £4,524, compared with £4,224 last year, being an increase of £300.

Golf.—The *Nottingham Daily Guardian* says Henley's Telegraph Works Company are promoting a golf tournament which should certainly prove attractive to the professionals, as the prize money is to amount to no less than £150, the only restriction being that the competitors should use one of the Henley Company's golf balls.

Southborough.—The Urban District Council have received a notice from the Guildford Electricity Supply Company, Limited, of their intention to apply in December next to the Board of Trade for a provisional order to supply the district with electricity for any public or private purpose. The Council will probably oppose the application.

British Light Railway Development Syndicate.—Under the title of the British Light Railway Development Syndicate, Limited, a company has been registered by W. T. J. Hooper, 23, Bucklersbury, E.C, with a capital of £10,000 in £1 shares, to prospect in Great Britain and Ireland for suitable localities for the construction of light railways, tramways, etc.

London Light Railways Construction Company.—Under the title of the London Light Railways Construction Company, Limited, a company has been incorporated to enter into contracts for the construction, repair, and maintenance of any works whatever, including railways and other roads or ways to be used for traction by electricity, steam, or other agency, also telegraphs, etc.

Pretoria (Transvaal).—The tramway company has obtained permission from the Government of the South African Republic to substitute electric for horse power, provided the townspeople express themselves in sympathy with the proposed change. The plant has already been ordered from England, and work is expected to be commenced early next month. The cost of construction is estimated at something like £8,500 per mile.

Northwich.—The clerk has reported to the Rural District Council that the secretary of the Northwich Electric Supply Company had asked the consent of the authority to the application for a provisional order which it was the intention of the company to make. The Council have already given their consent to the scheme. It was resolved to assent to the application of the company, subject to reasonable precautions.

Improved Incandescent Lamp Syndicate.—Under the name of Improved Incandescent Electric Lamp Syndicate, Limited, a com-

Digitized by Google

pany has been registered by C. W. and H. B. Taylor, 31, Crutched-friars, E.C., with a capital of £700 in £1 shares, in order to enter into an agreement with S. P. Eastwick and E. Sayer, and to carry on the business of electricians and electrical engineers in all its branches. The registered office is 130, Fleet-street, E.C.

Burnley. — At a meeting of the Electric Lighting Sub-Committee, on Thursday week, the electrical engineer was instructed to make enquiries in Yorkshire-street with a view of extending the electrical mains in that district, an application having been received from the authorities at a Catholic chapel for a supply of electric light. An extension of the main is also to be made in St. James-street, from Chancery-street to Calder street

Manchester —It was stated at the City Council that a further reduction had been made in the price of electricity to large consumers. The charge to such consumers had hitherto been 4s. per quarter per lamp and 2d. per unit of supply; it would now be 3s. per quarter per lamp and 1½d. per unit. That was equal to a reduction of 25 per cent, and it was hoped the result would be a great increase in consumption, particularly during the day hours.

Brockie-Pell Arc Lamp Company.—We are informed by Mr. B. Pell that the letters of allotment and regret in connection with the formation of the above Company were posted on Tuesday last, and the capital required was over-subscribed The Company, therefore, started on a financial basis as good as the lamp they are about to manufacture. All orders for the Brockie-Pell type of arc lamp should now be sent to the Company's offices, 14, Gracechurch-street.

Cardiff.—Mr. S. F. Walker has written another letter to the *Western Mail* criticising the design and management of the municipal electric lighting plant in connection with the recent breakdown. Practically, his letter comes to a suggestion that several small units should be worked instead of two large ones. The cause of the breakdown is known and has been published—it was not what Mr. Walker at first suspected—and a recurrence can, and probably will, be prevented in a much simpler way than Mr. Walker suggests.

Hampstead (London).—The Works Committee of the Board of Guardians have reported that they have received an estimate from the Exchange Telephone Company with regard to the workhouse being placed upon the telephone system and for communication being made between the workhouse and the medical officer's residence. The cost for the former was estimated at £25 per annum, with an additional cost of £9 per annum if an extension were made to the residence of the medical officer. It was decided to take no action in the matter.

Derby.—The Co operative Society have granted a lease to the Corporation for seven years at £1 per annum of a cellar in the basement of their premises at the corner of Normanton-road and Ambrose-street, for the purpose of fixing therein the transformer which now stands at the corner of the streets opposite their premises. The arc lamp-posts have been painted at a cost of £25. The Local Government Board have sanctioned the borrowing of £11,134 for electric lighting purposes. Sowter's road has been lighted with incandescent electric lights, and the cost per lamp ascertained to be £4. 12s 9d. per annum.

Glasgow.—The Corporation Tramway Committee met recently and considered the report of a sub-committee on the overhead system of electric traction. By the casting vote of Mr. Walter Paton, the convener, it was agreed to approve of the sub-committee's suggestion to adopt the system on the detached route from Springburn to Mitchell street, a distance of about 2½ miles, double track. The estimated cost for a three minutes' service is as follows: Overhead construction and rail bonding, £3,300; power-house, £2,000; generating plant, £6,000; feeders, £2 200; 15 new motorcars at £550 each, £8,250, less cost of 15 ordinary cars required and hereby superseded at £145, £2,175—£6,075 Total, £19 575.

Appointments Vacant.—In consequence of Mr. Rhodes's appointment at Salford, there is a vacancy at the City and Guilds Central Technical College for an assistant with a good knowledge of mathematical and experimental physics. The salary commences at £150 per annum, and application should be made in the first instance by letter to Prof. Ayrton, Central Technical College, Exhibition-road, London, S.W.—The Leeds Corporation want a clerk of the works for the electric tramway. Applications, stating experience and salary required, should be sent to the Town Clerk. The Corporation of Bristol want a charge engineer at £2 a week. Application is to be made to Mr. Faraday Proctor, city electrical engineer, Temple Back, Bristol.

Liverpool.—At a meeting of the Lighting Committee a letter was read from Sir Arthur Forwood, M.P., the chairman, resigning his position as chairman on the ground that he will be unable to give the increased time and attention to the duties necessitated by the handing over of the Electric Supply Company's undertaking to the Corporation. Mr. Petrie was then appointed chairman, the position of deputy-chairman being awarded to Mr. J. S. Harmood Banner. The committee resolved to instruct Mr. A. B Holmes, electrical engineer, to carry on the manufacture, sale, and arrangement of fittings as heretofore, but directed that if an application was received to place fittings outside the area of the city or port of Liverpool or the borough of Bootle that matter must be brought before the committee.

Fort William (Inverness).—The works in connection with the Fort William Electric Lighting Company, Limited, are nearing completion. So far advanced is everything that on Saturday and Sunday the light was turned on in the accumulator-house. The street cables have been laid and the overhead wires are all but completed. It is anticipated that all the churches, hotels, and private houses which have already been wired will be connected within the next fortnight. The Station Hotel is to be illuminated throughout from the company's works. It is understood the hotel is fitted with about 350 lights. As if to encourage the electric light the Fort William gas supply failed on Sunday night, and, as has been done on similar occasions, candles and paraffin lamps had to be resorted to by the inhabitants.

Gateshead.—The Parliamentary Committee have reported as to the desirability of the Corporation making application to the Board of Trade for a provisional order empowering the Council to supply electricity in Gateshead, as, in the opinion of the committee, any system of electricity in the borough should be in the hands of the Corporation instead of a private company. The Newcastle and District Electric Lighting Company, Limited, had recently intimated that they had abandoned the idea of obtaining a provisional order for the supply of the electric light in Gateshead, and as no notice had been received from any other company, no application could now be made to the Board of Trade for a provisional order except by the Corporation. Under such circumstances they recommended that for the present no action should be taken by the Council to obtain the necessary order. Alderman Lucas said the committee had been engaged for some time in gaining the fullest information on the question of electric supply. The committee had by no means abandoned the undertaking, and, whilst anxious to keep the supply in their own hands, were in no hurry so long as there was no immediate chance of any rapid development. The report was adopted

Islington (London).—The report of the Electric Lighting Committee, which comes before the Vestry to-day (Friday), states that with reference to the action in the Clerkenwell County Court by Mr. A. T. Young, cab proprietor, for damage to a hansom cab alleged to have been caused by its coming into collision with street refuge in the Upper-street after the electric light on the refuge had been turned out, the vestry clerk reported that notwithstanding the summing up of the judge to the effect that there was no evidence to show that the Vestry had improperly exercised the discretion vested in it by Section 130 of the Metropolis Management Act, 1855, the jury had found a verdict for the plaintiff (the damages, if the Vestry were liable, having previously been agreed at £30), but that the judge had, upon the application of the Vestry's solicitor, caused judgment to be entered for the Vestry on the grounds above stated. The solicitor for the plaintiff had since given notice of appeal, and the Vestry's solicitor had been instructed to take all steps necessary to support the judgment. It was further added that in the early morning of the 24th ult. (the judgment above referred to having been given on the 23rd ult) two hansom cabs were reported by the police as having come into collision with the same refuge when the light was turned out, and that a claim had been made in one case by the owner for compensation. Having regard to the judgment in the previous case, the committee instructed the vestry clerk to write repudiating any liability.

Electrical Development and Finance Corporation, Limited. Under this title a new company has been formed, with a capital of £500,000, in £1 shares, of which 250 000 are now offered for subscription. The prospectus states that the Corporation has for its primary object the promotion and development of undertakings for utilising electrical power in all its industrial applications, and its business will not be confined to the British Isles, but it is proposed to be extended to the Colonies and foreign countries. The directors attach importance to the field for enterprise presented by the transmission of electric power for mining and other purposes from existing water powers, and by electric traction for tramways. The latter subject is now receiving serious attention from tramway companies, engineers and capitalists, and the Corporation anticipates a considerable revenue from the promotion and development of electric tramway undertakings. It is added that the Corporation intends commencing operations at once, and has under consideration the exploitation of a new and improved system of electric traction, the electric lighting of an important and rapidly-growing district, an interest in a new and thoroughly practical self-starting alternating current motor, and the construction of a system of electric generating stations and the transmission of power in a mining district of South Africa. The Board consists of the Duke of Newcastle, Mr. W. Crookes, F.R S (Notting Hill Company), and Mr W. C Johnson (Johnson and Phillips, Old Charlton), and Mr. Medhurst is the consulting engineer. The subscription list closes to-day (Friday) for London and to-morrow for the country. The temporary offices of the Company are at 24, Coleman-street, E.C.

Kingston-on-Thames.—The electrical engineer has reported to the Lighting Committee that the first electric launch was charged on June 8 The Thames Conservancy have agreed to piles being fixed where the launches are to be charged. The committee has assented to the conditions imposed by the Surbiton District Council for the supply of current from the Corporation works to the assembly rooms, subject to a satisfactory agreement being submitted. The draft agreement with the Maldens and Coombe District Council respecting the supply of electricity in their district was approved, subject to modifications, and the Council was recommended to authorise the affixing of the seal to the agreement—the effect being that the Corporation would have the right, subject to the approval of the Local Government Board and the Board of Trade, to supply electricity in Coombe, and, if subsequently agreed, in New Malden and Old Malden, and that an application would be made to the Board of Trade for authority to extend the electric main to such district. Councillor Kitching asked what was the cost of the 1,300 yards of cable necessary to convey the current from

Digitized by Google

Kingston-hill Post Office to a house half-way up Liverpool-road, and what return was expected from the house where the light had been put in. Councillor Collings said the cable was taken to Liverpool road because they were compelled to take it there, having obtained the approval of the Local Government Board to the loan on condition that they would put a main there when requested. As soon as a customer came and asked for it, being within the compulsory area, they were obliged to do it. The cable cost about £240, and the revenue from the house would be about £34 a year, but of course other houses would come on to the same cable. The report was subsequently approved.

Coventry.—In moving in the Town Council that the Electric Light Committee should be instructed to prepare and submit a scheme and an estimate of the cost of electric lighting for Hertford-street, Broadgate, Crosscheaping, Burges, Bishop-street, Smithford-street, High-street, and Earl-street, Mr. West said his motion simply asked the Council to become customers to their own undertaking. Mr. West then proceeded to read the opinion of Mr. Hammond, their consulting electrical engineer, to the effect that the benefits to the electricity works itself of a public lighting business are now becoming generally recognised. One of the greatest advantages which accrued to works dealing with public lighting was the material assistance given to the lowering of the cost of production by the long hours of burning of the street lamps. Street-lighting was an advertisement for the undertaking. According to the latest statistics it was considered that from 1½d. to 2d. per unit was sufficient to cover the cost of public lighting supply. Mr. West estimated the total cost for gas in these streets to be dealt with at £217. 11s. 9d., while Mr. Ram, the Council's electrical engineer, estimated that in these streets could be put up 22 800 c.p. lamps at the cost of £18 each per annum, and these would light the streets well. This would include half the lamps burning from 12 o'clock midnight until daylight, and would average 3,000 hours per year for each lamp. The 22 electric arc lamps of 800 c.p. at £18 each per annum would make a total cost of £396. These 22 lamps would equal 17,600 c.p., as against the present illuminating power of the gas lamps of 1 885 c p. If the price he had named was accepted by the committee it would compare with gas thus: gas, 100-c.p. lamps, £9 each; electricity, 800 c.p. lamps, £18 each. He would simply leave the matter upon its merits, and ask the Council to send the motion to the committee for further investigation. Mr. Goate seconded. Alderman Tomson, as a member of the Electric Light Committee, said he could not support the proposition. In the first place it was not at all clear that the arc light would be suitable for such narrow streets. Ultimately the resolution was lost by five to ten votes.

Bolton.—The electric lighting extensions of Messrs. Tootal, Broadhurst, and Lees's Daubhill Mills is to be done by Messrs. Drake and Gorham. Mr. W. Druce, Manchester, is the consulting engineer. The proceedings of the Joint Sub-Committee on electric traction have been confirmed at a meeting of the Streets Committee. It appears that the tramway lessees are not prepared to comply with the Corporation's proposals as to electric traction. The town clerk has been requested to advise as to the proceedings to be taken by the Corporation for carrying into effect the proviso contained in the tramways lease for the adoption of mechanical traction, and it was resolved that a communication be made to the Urban District Councils of Astley Bridge, Farnworth, and Kersley inviting a conference upon the adoption of electric traction on the Bolton and suburban tramways generally. The Gas and Electricity Committee have deferred consideration of the application of Messrs. Gillibrand and Hodgkinson for the supply of electricity to their premises in Bridgeman-place. The question of making alterations to the steam separators in the engine-room at the electricity works was referred to the chairman and engineer. The attention of the Manchester Edison-Swan Company, Limited, was ordered to be again called to the slow progress made in the carrying out of their contract for additions to the switchboard. A resolution of the Streets Plans Sub-Committee was read making application that the electrical engineer be allowed to make an examination and report upon an electric installation to the new premises of the Great and Little Bolton Co-operative Society, Bridge street, as required by the Board of Trade, and it was resolved that the electrical engineer examine and report. The engineer submitted a statement of further capital expenditure required for the purposes of the electricity department, and it was resolved that application be made to the Local Government Board for sanction to borrow money to the amount of £35,000 for electrical purposes. It was decided that the charge for superintending electric fitting works required by consumers be 5 per cent on the cost of such work, and that the resolution adopted by the committee on June 26 be altered accordingly. The Town Council passed the reports.

Bedford.—The committee have reported to the Bedfordshire County Council as to installing the electric light in the shire hall and county offices. The report as presented a year ago was read, showing that the estimate for lighting the hall, offices, lavatories, etc., was £79, and the rest of the building £145. 16s. The surveyor now reported that in accordance with instructions he had asked for prices from four firms for lighting only at present the portions requiring nightwork—viz, the offices of the clerk of the peace and county surveyor and the main entrance and corridors approaching thereto. The contractors had also been requested to include in the price a sufficiently large main supply to eventually complete the whole building, if so desired, or any section of the building, as from time to time might be determined upon. Messrs. Laing, Wharton, and Down, of 82A, New Bond street, London, offered to lay in a supply main to the distributing board for 250 16-c p. lights and wires, the corridors and offices of the clerk of the peace, also the county surveyor's offices, and prepare same for the fittings (which were not included) for £34. 15s. Messrs. Ellis and Ward, of Birmingham, agents to the Brush Electrical Engineering Company, Limited, quoted upon a very limited specification, saying they had included sufficient mains for this lighting only, with a slight margin for one or two extra lamps. It, however, would be possible to extend this lighting all over the building by the addition of heavier cables as required. Their price for 19 lights was £25, and the probable cost for the larger service to the distributing board might be estimated at about £5 more. Mr. Henry Bacchus, of Bedford, had submitted the following estimate: The cost of electric lighting installation at shire hall for 22 lights complete, with main wires sufficient to carry same, would be £32. If extra large main wires sufficient to carry an additional 100 lights for future extension, £5 extra. This price was complete with two distribution boxes. All office lights to have counterweights for raising and lowering. Messrs. Kilpin and Billson, of Bedford, had tendered upon a very clear and sufficient basis of a main supply for the whole building as far as the distributing board, from which point the present suggested partial lighting should be served, and any other part or whole later on. Their price for the suggested installation of 20 lights and larger cables was £29. 10s. Mr. Leeds-Smith said electric lighting appeared to be in its infancy; £30 was now the estimated cost for what a year ago was £80, so he was encouraged to think that if the matter were left another year the cost would grow considerably less. He therefore moved that the matter stand over. The Clerk pointed out that the estimate was less now than before because the area proposed to be lighted had been much reduced. Mr. Whitworth remarked that the courts and most of the rooms in the shire hall were used only occasionally at night, so it was immaterial whether they were lighted by gas or electricity. Ultimately, Mr. Cole said he never knew anyone who adopted the electric light go back to gas, and he moved that the matter be referred to a sub-committee to decide which firm the work should be entrusted to. This was agreed to.

Belfast.—The committee have reported to the Town Council that they have had under consideration the probable necessity of increasing the present gas-driven plant in their central station, as that now available will in all likelihood be fully utilised before the extension of the system proposed can be taken in hand. The committee add that it is satisfactory to know that the engineer's report shows a fair surplus over the working expenses. Councillor Andrews, in moving the adoption of the report, said the committee had not yet arrived at any definite conclusion as to the amount of plant that would be at present required, but they roughly estimated it as equivalent to about 7,000 more lamps, bringing up the possibility of wiring to 20 000 lamps. At the present time their safe limit was almost fully occupied. They had about a free margin of 1,000 8-c.p. lamps. Therefore it was absolutely necessary for the committee to take this matter of increased generating power in hand within a short time. The makers of the last engines, which had been going fairly satisfactorily, said they now saw where the difficulty existed, and that they could overcome it and deliver an engine, or a couple of engines, within a very short time. The difficulty would be in getting dynamos, the makers being so busy at the present time preparing for the coming winter season. The committee would probably report to the Corporation next month that they had entered into negotiations for the erection of further plant, so that consumers need not be anxious about being short of supply in the winter. It was rather early yet to bring forward the larger scheme, which had been reported to the Council. The outlay would be so large that it would have to be included in the report of the Finance Committee for next year. It would amount, he might say roughly, to about £100,000, and that would give them a supply sufficient to enable fully six times the present number of lamps being wired. Councillor Herdman seconded the report. Councillor Woodside enquired whether gas-engines were most economical. He also wished to know whether the makers of the engines were responsible for the cost of altering them where they did not work satisfactorily. Councillor Young said that if it went forth that the Electric Committee were making a large profit, the ratepayers would think they were being charged too much for the electric light. It was misleading to say there was a fair surplus, because really there was no surplus at all. They had borrowed £30,000, and the interest on that was not provided for, nor was there anything for a sinking fund. He protested against any increase of the driving power at the present central station. The sooner they got out of the present station and on the banks of the Lagan the better. Councillor Barklie said the present station was not initiated by the members of the Electric Committee but by the Gas Committee. He had no doubt that when they got steam they would be able to supply electricity at a cheaper rate. Councillor Andrews said they were at present paying nearly three times as much for their fuel as they would with a steam-driven engine. With regard to the last two engines, the makers were bearing all the expense of making them efficient. With the high cost of fuel they could not possibly make any show in the way of earning a profit, but if electric lighting went on as it had been going on in Belfast there was no doubt they would be able in time to show a surplus at least sufficient to pay interest. The report was then adopted. The report of the Belfast Street Tramways Company states that the directors regret that up to the present they have not been able to come to terms with the Corporation for the working of the Belfast tramways by electric traction. In the meantime the company's Bill authorising the use of electric traction

Digitized by Google

has been passed, but subject to the sanction of the Corporation being first obtained. The whole matter now, therefore, rests with the Corporation.

PROVISIONAL PATENTS, 1896.

JULY 27.

16551. Commutator protector. Allan Burgess Roxburgh and Thomas Dowler Green, 30, Goldsmith-road, King's Heath, Birmingham.

16566. Improvements in or relating to electric bells or signals. John Rendell, 16, Long-street, Devizes.

16592. Connecting plug for telephone cords. Burton Hawke and the London Electric Wire Company, Limited, Playhouse yard, Golden-lane, London.

16597. Improvements in and relating to primary batteries. René Marie Joseph Heurtey and Pierre Germain, 111, Hatton-garden, London.

16602. An improved protective device for the dispersing lenses of light projectors. Henry Harris Lake 45, Southampton-buildings, Chancery-lane, London. (Elektricitäts-Actiengesellschaft vormals Schuckert und Co., Germany.) (Complete specification.)

16608. An improvement relating to magnetic compasses. Joseph Daniel Rowbotham Blain, 166, Fleet-street, London.

16629. Improvements in the construction of electric cables. Joseph Daniel Rowbotham Blain and William John Pawson, 166, Fleet-street, London.

JULY 28

16644. Improvements in the means of attaching metal contacts in electrically-controlled and other gas burners. Frederic Richard Boardman, 238, Tottenham Court-road, London.

16657. Improvements in means or apparatus for the measurement of electric energy. Georg August Julius Telge, 55, Chancery-lane, London.

16683. Improvements in alternating electric current transformers. John Alexander McMullen, 124, Chancery-lane, London.

16726. Improvements in electrodes for secondary batteries Friedrich Wilhelm Schneider, 18, Buckingham-street, Strand, London. (Complete specification.)

16729. Improvements in the manufacture of caustic soda and other alkaline hydrates and compounds by electrolysis. Leonard George Attenborough and Evan Aspray Sulman, 111, Hatton-garden, London.

16737. Improved apparatus for generating or collecting electric energy. Joseph Daniel Rowbotham Blain, 166, Fleet-street, London

JULY 29.

16790. Telegraph-wire reel. Heinrich Ehricht, 10, Friedrichstrasse, Berlin. (Complete specification.)

16801. Improvements in electrical cut-outs. Armand Farkas, 2, Lancaster-place, Strand, London.

16852. Improvements in electrolysis. Gradon Poore, 70, Chancery-lane, London (Complete specification.)

JULY 30

16894. Improvements in and relating to instruments for measuring electric currents. James Finlayson, 62, St. Vincent-street, Glasgow.

16916. Apparatus for obtaining oxygen and hydrogen from steam by electrolysis. Edmond Strzelecky, 28, Southampton buildings, Chancery-lane, London.

JULY 31.

17001. Electrolytic manufacturing of cyanide of alkali. Robert Pauli, Oldbury. near Birmingham.

17025. Improvements in incandescence electric lamps. Thomas Archer Rose and Rose and Bird, Limited, 55, Chancery-lane, London.

17044. Improvements in and connected with apparatus for lighting and extinguishing gas jets by means of an electric current. William Edwards, 11, Furnival-street, Holborn, London.

AUGUST 1.

17088. Improvements in electric batteries. Henry William Headland, 77, Chancery-lane, London

17093. Improvements in counterbalance weights for electroliers, gasoliers, and other suspended fittings. George Montague Sellick, 70, Chancery-lane, London.

17098. An automatic electrical switch or exchange. Andrew Sautter and John J. Sautter, 104, Peckham-road, London.

17101. Improved electrical switch. James Hermann Field, 28 Southampton-buildings, Chancery-lane, London.

17103. Improvements in or applicable to phonographs. The Edison-Bell Phonograph Corporation, Limited, and Augustus Stroh, 191, Fleet-street, London.

17122. Improvements in metallic junction-boxes and means for uniting metal conduit-tubes thereto and to each other. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Edwin Truman Greenfield, United States.) (Complete specification.)

17123. Improvements in insulating joints for metal or armoured conduct-tubes, more especially suitable for electrical conductors. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Edwin Truman Greenfield United States (Complete specification.)

17124. Improvements in and connected with conduits, more especially suitable for electrical conductors. Henry Harris Lake 45 Southampton-buildings, Chancery-lane, London. (Edwin Truman Greenfield United States.) (Complete specification.)

17125. Improvements in conduit-tubes, more especially suitable for electrical conductors. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Edwin Truman Greenfield United States.) Complete specification.

SPECIFICATIONS PUBLISHED.

1895.

13113. Telephonic installations. Lake. (Baivy.)

13175. Telephone exchange switchboards. Stock.

16897. Holders and supports for electrical candles Hirst and Gibson.

17782. Electric contact for use with clocks and the like. Wall.

18870. Electromotors and transformers. Langdon-Davies and the Alternate-Current Electromotor Syndicate, Limited.

1896.

4617. Electric railways. Coerper.

6437. Current collectors for electrically-actuated tramway vehicles on the conduit system. Lake. (Union Elektricitäts Gesellschaft.)

9171. Electric railways on the conduit system. Fairweather. (Munson, Roberts, Alston, Reid, and Reid.)

10047. System of and means for electrical transportation. Stern.

10772. Starting and stopping devices for electrically-operated elevators. Otis Elevator Company, Limited. (Otis Bros. and Co.)

12650. Thermo-electric generators. Cox and the Cox and Thermo-Electric Company.

NOTES.

The Electric Railway.—There was some kind of a breakdown on Thursday week on the City and South London Railway, but whatever was the matter was soon put right and traffic resumed.

Tennessee Exhibition.—There is to be a centennial exhibition at Nashville, Tennessee, next summer. The United States Government have nothing to do with it, though they give facilities so far as the Custom House is concerned, but the State authorities hope for foreign exhibits on a considerable scale.

Electric Locomotive.—The Westinghouse electric locomotive, which is to be examined by the officers of the New York elevated railways with a view to having trials made, has been described by the *Engineering News* as resembling "a street car mounted on four-wheel trucks." Each truck (bogie) has two Tesla polyphase motors.

Street Box Explosion.—An explosion took place in the electric light surface box at the corner of Vere-street and Oxford-street about half-past nine on Wednesday evening, which was probably due to a leakage of gas into the box. No one was hurt, but the pavement was thrown over, and, of course, a large crowd was attracted by the noise.

Motorcarts.—The Lords have agreed to the Commons' amendments on the Locomotives of Highways Bill, which therefore only awaits the formality of the Royal assent. A financial contemporary in noting the fact speaks of the measure as the "Auto-Motor Car Bill," which seems a distinctly pleasing deviation into absurdity in the way of nomenclature.

American Tramcar Accident.—At Columbia, in Pennsylvania, last Sunday, a tramcar ran away downhill, jumped the rails at a curve, capsized into a ditch, and killed five of its occupants. Already this accident has been put down to the fault of electric traction, instead, of course, of being ascribed to its true cause—namely, want of effective brakes.

Light Railways Association.—Although the work of this association has been done so far as promoting legislation is concerned, it has been decided to continue its existence, "as one means, in co-operation with other organisations, of carrying out the powers in the Bill by affording information and assistance and facilitating the construction of light railways."

Associated Chambers of Commerce.—At the meeting to be held at Southampton next month resolutions will be submitted urging the necessity of improving the trunk line telephone communications, and the advisability of the compulsory adoption of the metric system, and also calling attention to the slow progress made in relation to direct cable communication with the Colonies.

The Telephone Girl.—The Telephone Girl Company, Limited, has been registered, and that, too, by a firm in Victoria-street. Nevertheless, its object is not to furnish the National Telephone Company with an article that shall better meet the wants and wishes of its customers than anything that company has hitherto been able to supply. In fact, the new company is a purely musical and dramatic affair. There is a company which proposes to do away with the telephone girl altogether—but that is another story, and is therefore told elsewhere.

The Metric System.—It has been stated by people that ought to know that it is at present actually illegal to possess a weight or measure on the metric system. In the piecemeal way in which legislation is effected in this country it is quite possible that this may have been brought about without anybody knowing it. If so, it is appalling to think of the august institutions that have been encouraging this illegality. Most people, including the writers of some text-books, thought the metric system was legalised years ago by 27 and 28 Vict., cap 117.

Death of Captain M'Callum.—The British Consul at Beira has received and forwarded on a despatch from Major Forbes received by a runner from Chinde stating that Captain M'Callum, the constructor of the African trans-continental telegraphs, was murdered by Mashonas at Matetimi on June 25. The attack was entirely unprovoked, and loot was the only excuse. Major Forbes did not anticipate any check to the work beyond the bad effect on the "boys"—*i.e.*, the native workmen—but at the time of writing the despatch he was evidently unaware of the state of the country and the Mashona revolt.

Ushant Lights.—It is stated that an exchange of communications has taken place between the British and French Governments on the subject of an exhaustive survey off Ushant and the neighbourhood. The survey is to extend to at least 10 miles out, and two or more lighthouses telegraphically connected with the shore may be constructed. Considering that the loss of the "Drummond Castle" was in no way due to any fault of the French lighthouse service or to inaccurate charting of the coast, but to quite other causes, the readiness and goodwill displayed by the French authorities is most commendable.

Telegraph Troubles.—Some boys were had up before the magistrates at Ipswich the other day, and fined for smashing telegraph insulators. Incidentally, the district engineer of the Post Office Telegraph Department stated that no less than 56 insulators had been destroyed, and great inconvenience had been caused by it. The rest of Suffolk has always refused to be responsible for the sins of Ipswich, which is in it but not of it. But those Ipswich boys must be terribly good shots with a stone for 13 insulators in the day, and an aggregate of 56 must be something near the "record" score in insulator smashing.

A Modern Icarus.—We are sorry to hear that Mr. Lilienthal has met his death while in pursuit of his experiments in the art of learning to fly. He despised the assistance of motors, and using wings only was able to manage long swoops of 200 or 300 yards, but was not much good at rising. This week, however, when on one of his flights at Colenberg, in Prussia, a gust of wind toppled him upside down, and he was dashed violently to the ground and killed. The path of the contriver of flying machines is a dangerous one. The original, and by all accounts most successful inventor of them all, seems to have given it up after he had lost his son—and, what is worse, no one has ever been able to find his working drawings.

Water-Jets as Conductors.—Some time ago we noted that some American firemen received electric shocks which they believed were communicated through the jet from a fire-engine hose. Considering what a particularly good earth a fire-engine must have in its suction pipe it seemed unlikely, but it appears that so far as alternating currents are concerned the matter has been already determined experimentally by Prof. Slaby, of Berlin. The overhead conductors of a 10,000-volt power transmission line were used for the experiment. A voltmeter was connected between the metal mouthpiece of the water-hose and the earth. On turning the water on to the live conductors no flow of current to earth was noticeable.

Our Chinese Visitor.—According to the arrangements made for him to-day (Friday), Li Hung-Chang is to go to Greenwich to visit the cable factory of the Telegraph Construction and Maintenance Company, at Enderby's Wharf.

Digitized by Google

There is, of course, to be a dinner, or whatever is the proper name for it, and it is understood that the Eastern Telegraph Company is to do some things in the way of telegraphy to distant parts of the world which have not been done before—even in America. But whether his Excellency Li Hung-Chang will have anything particular to say to his friends in Pekin, and whether those friends, instead of going to bed at the usual Chinese time, will sit up and make a night of it, in order to answer him, remains to be seen.

Police Calls.—In reference to the letters to the *Times* which we briefly commented on last week, the secretary of the District Messenger Company says that a policeman was not sent to Mr. Norman, as one could not be found at the usual points. As Mr. Norman himself complains that there are not enough policeman in Grosvenor-road to meet the requirements of that neighbourhood, this sounds plausible. Moreover, there was a successful burglar-hunt going on at the time, which would naturally occupy their attention. Mr. Macdona did not get his policeman because his signal was indistinct. The company do not appear to have arranged to "stock" either policemen or fire-engines, but with regard to the latter "they have made proposals to the Fire Committee of the London County Council."

Mining Engineers.—The students connected with the Federated Institution of Mining Engineers, after their second annual conference in Leeds last week, paid a visit to Micklefield for the purpose of inspecting the scene of the recent explosion. Messrs. Cliff and Sons, the owners of the Peckfield Pit, gave the students every facility for viewing their property, the manager, Mr. C. Houfton, and Messrs. Hargraves and Holliday, who are also connected with the firm, conducting the party underground, where a thorough inspection of the various appliances and machinery was made. The party having returned to Leeds had an opportunity of inspecting the Yorkshire College and the central electric lighting station of the Yorkshire House-to-House Electricity Company, Limited. The next day there was a visit to the Ackton Hall Collieries, Featherstone.

The Pacific Cable.—In the House of Commons on Tuesday night, on the Colonial votes coming up, Sir Charles Dilke expressed the hope that the Government would do their best to develop cable communication with Australasia *viâ* Gibraltar, Sierra Leone, and the Cape, and urging that this route had strategic advantages which the Canadian Pacific route would not possess. Mr. Chamberlain, without discussing the question of strategic advantages, observed that both Canada and Australia would give good subsidies towards a Canadian Pacific cable. That, of course, is a good reason, but the Colonial Secretary, if he had chosen, could easily have defended the Pacific route on its merits. In case of war the only safe thing for an enemy's ship in the Pacific to do would be to get into a neutral port as quickly as possible and stay there. There is only one European Power that could be really troublesome in a maritime war, but owing to our practical abandonment of East Africa that Power would have the Sierra Leone sections of the other route very much at its mercy.

American Patents.—The growth of the patent system in the United States of America is clearly set forth in the fiftieth anniversary number of the *Scientific American*. Up to the end of 1845 only 3,873 patents had been granted, and the number issued that year was only 503. Now the total number has risen to the grand total of 531,619, and the number issued in 1895 was 22,057. In the classified list of total patents we are pleased to see that electrical inventions take the third place with 18,052 patents, while the highest number is 20,821 for carriages and wagons. The most prolific inventor, or, more correctly, the man with the largest control over inventions, is Edison, who has no fewer than 711 patents under his name. Elihu Thomson comes next with 394, followed by F. Richards, E. Weston, C. Scribner, Depoele, and Westinghouse. The majority of these men have taken the greatest interest in electrical matters. The writer of the prize article on the above subject claims that the beneficial character of the American patent laws has done much to assist the country into its present position.

Chemical Society.—The last issue of the *Journal* contains some interesting matter. Mr. Masumi Chikashigé, of the Japanese Imperial University, contributes a short paper on the atomic weight of tellurium. This, as is well known, is not what it might be expected to be. Mr. Chikashigé determines it from Japanese tellurium at 127·6. The only importance of the matter is its bearing on the validity of Mendaleieff's law. Dr. Fitzgerald's Helmholtz memorial lecture is reprinted. A great deal of space is occupied by Dr. Kipping's researches on camphoric acid derivatives at the Central Technical College. To anyone not engaged in that particular branch of inorganic chemistry this paper is pretty stiff reading. There is a sort of supplement to it by Mr. W. J. Pope. Short notes in the abstracts show that Mr. E. A. Hill, in America, and Mr. R. M. Deeley do not believe argon and helium have monatomic molecules. Probably time will prove them right. At present there is a decided tendency to push the Maxwell theory of gases with a vigour which is hardly warranted by the "statistical" basis on which it rests.

Military Telephones.—Captain Charollois has communicated to the French Society of Civil Engineers some interesting experiments he has made in this direction. He has been investigating the distance at which conversation is possible if a bare wire is laid direct on the ground with earth return. In spite of the leakage to earth along such a line, he has found that speech can be transmitted perfectly over a line 15½ miles long. The ordinary call bells cannot, however, be used, and hence Captain Charollois has devised a magneto call to act on the diaphragm of the receiver. We consider the experiment most interesting as showing how bad a circuit must be before a telephone will refuse to act, but not as a guide to general practice in such work. We remember an instance some years ago in which a telephone erected as an attraction at a local flower show worked comparatively well although a portion of the circuit was completed through the canvas of a tent. The wire had broken, and the bare ends, held a few inches apart by the insulation, rested against the canvas of the tent inside which the telephone was working.

Salmon or Turbines.—We have already noted the attitude of the tourist on the subject of the utilisation of water power—he is generally the man who when he gets home writes to the papers suggesting general incompetence in the whole class of engineers because they do not make use of "the forces of Nature." Now, however, it is the fisherman who is giving trouble, and it is the salmon, not the landscape, that is sacrosanct. At the meeting of the Derwent Fishery Board Mr. Hall wanted a grating six or seven yards long and 4ft. high put up at the Keswick electrical works, for fear salmon might get into the watercourse and be chopped. The matter was left over to enable the clerk to look into the question of liability. The fisherman, however, seems much more reasonable than the tourist, and if he will be contented with a grating, no one will want to deny it to him. But, on the other hand, consideration for the convenience of the salmon has trebled the distance of the Fort William generating station from that town, and, moreover,

Digitized by Google

compelled the company to do with a much smaller and less convenient water supply than would otherwise have been available.

Telephones in Japan.—According to the *Western Electrician*, at present there are several distinguished Japanese visitors in Chicago engaged in examining into the methods employed in electrical enterprises of various kinds there. Several of them have a Government commission to make a careful study of telephony. It is especially interesting, therefore, to note the announcement that engineers of the Department of Communications of the Imperial Government of Japan have received instructions to prepare estimates of cost for the surveying, designing, and installation of an extensive telephone system that will connect every portion of the islands with metallic service. The long-distance lines of the proposed system will altogether aggregate 25,000 miles in length, and the plan contemplates the establishing of 40 main offices and 180 public stations, which will be capable of handling 25,000 subscribers. At present telephone exchanges are in operation in Yokohama, Tokio, Osaka, and Kiobe, while next month an exchange will be in operation in Kioto. The system will embody both land and submarine construction, and the line construction will probably be begun next summer.

Institution of Electrical Engineers.—We have already acknowledged the receipt of the *Journal* of the Institute of Electrical Engineers, giving the last two papers of last winter's session. Mr. W. G. Rhodes's mathematical treatment of the subject of the iron loss in transformers as affected by the wave form is now available for criticism. Written in a condensed form on the blackboard, it was at the time of the discussion wholly lost on the majority of the audience. Messrs. Cowan and Still's paper before the Northern Society of Electrical Engineers, dealing with the regulation of pressure in alternating-current supply systems, is reprinted in full, and in the larger type as an "abstract." There is a falling off in the hitherto large percentage of Röntgen ray abstracts. Of these Prof. Goldhammer's (from *Wiedemann's Annalen*) and Mr. Zickler's deal with points of importance. There are several valuable abstracts from the *Beiblätter*. A description of Dr. Jacques's carbon-soda-iron battery is taken from an anonymous writer in *L'Eclairage Electrique*, which seems a roundabout way to get an account of an American invention. The abstract contains no information that has not been published in English in our Transatlantic contemporaries. At the end of the *Journal* the proceedings at the members' meeting of July 6 are given, and the receipts and expenditure and the balance-sheet for 1895 are appended.

Incandescent Lamp Tests.—Some tests of incandescent lamps were recently carried out at the New York Exposition by Messrs. Stone and Webster, comparing six lamps of the Edison type with six Imperial lamps. No particulars are given as to how the lamps were selected for the trial, but they were all rated by the respective makers to give 16 c.p. at 110 volts. This they did, and the average watts per candle for the Edison lamps at the start were 3·1, while the Imperial lamps took an average of 3·45 watts. After a 600-hour run only two Edison lamps and four of the Imperial type remained. The rest had burnt comparatively early in the run. The candle-power and efficiencies at the end of 600 hours' continuous burning are in favour of the Imperial lamps. These four lamps gave candle-powers varying from 14·5 c p. to up 15·6 c.p., with an average efficiency of 3·7 watts per candle. The two Edison lamps gave then 11·7 c.p. and 11·9 c.p. and took 3·75 watts per candle. We understand from our New York contemporary *Electricity* that these tests were the cause of some feeling between the two firms at the time. In such experiments the selection of the lamps can be made to have a most important influence; but, after all, it is tests on lamps as sold that the public require. It is specially worthy of note that of the dozen lamps here experimented with only seven survived a 200-hour run. This loss seriously depreciates the value of the lamp from a consumer's point of view.

Car-Wheel Grinding.—The fact that tramcar wheels frequently wear unequally has been often observed in this country. Hence the value of the apparatus for remedying this evil invented by Murphy, of Pittsburgh, will be appreciated. It is described and illustrated in the current number of the *Street Railway Journal*. The method employed is that of using emery-wheels to true the wheel faces without removing the axle from the car. The emery-wheels are mounted on slide rests on a firm foundation, and are driven by belting from an overhead countershaft. This in turn is driven by a motor. The following is the method of working: The journal-box lid is first removed, which exposes the end of the axle. The car is then jacked up till the wheel stands about 1in. clear of the track. Then a male centre on the machine is adjusted to the centre in the car axle and pushed home. This ensures that the emery-wheels will always work at a given radius. The emery-wheels are then started revolving at the edge of the wheel. At the same time the car wheel is made to revolve by its own motor at about 100 revolutions per minute. Then, as the cut is taken, the emery wheels are fed in by the movement of the slide rest. It is claimed that by this machinery a wheel can be ground up true in from 20 to 30 minutes. As it would take almost as long to dismantle the gear if the axle was to be removed to be ground elsewhere, the saving, both in labour and time, would more than warrant the first cost of the above simple machinery.

Northampton Institute.—The vacant appointments at the Northampton Institute, Clerkenwell, have been filled at a meeting held on Monday last. The following were the successful candidates: The head of the mechanical engineering and metal trades department is to be Mr. John Ashford, who has been for the last three years lecturer on engineering at the Birmingham Technical Schools. Mr. Ashford has great experience of the metal trades of Birmingham, and his classes there were largely attended by students of the same type as are expected at the Northampton. The head of the artistic crafts department is Mr. John Williams, who has for several years taken an active part in the movement for the advancement of the decorative handicrafts, and during the last five years as senior instructor and inspector to the Surrey County Council organised and arranged the system of handicraft teaching with successful results. The chief assistant in the applied physics department is Mr. C. V. Drysdale, a distinguished student of the Finsbury Technical College and the Central Technical College, South Kensington, where he obtained two diplomas of associateship in physics and engineering respectively. Since his college training Mr. Drysdale has been for three years employed with Messrs. Nalder Bros. and Co., the electrical instrument makers in Clerkenwell. In the domestic economy school the head teachership has been conferred upon Miss Mary A. H. Gibbs, and the subordinate appointments are Miss G. G. Hardy and Miss Morgan.

Carrying Goods on Street Railways.—The practice of carrying goods on tramways is, we believe, somewhat new in this country. There are many tramlines where personal luggage is charged for, and one or two where small parcels are delivered *en route*. The running of cars

Digitized by Google

for a goods traffic only is, however, a paying branch of several lines in America. It is not allowed to interfere with the passenger traffic, but with long suburban lines that can be easily avoided. The *Street Railway Journal* has been collecting information under this heading, and finds that of 199 companies 136 do not attempt a service of this kind. The remaining 63 companies who do carry goods send in conflicting evidence as to the profits to be made. The majority of these carry mails, and most of the contracts for such work show a profit. The general goods required to be carried vary very much with the district. Thus, one company has established a most paying traffic in vegetables. Sidings have been provided to the various market gardens, and the goods are carried over the companies' lines to the railway depôts. In this way the object of our Light Railway Bill is fulfilled, and the profit of the line increased by the combination. We shall be only too pleased to see the tramlines round London equipped electrically, and when this has been done we believe that the same class of traffic would add largely to the revenue. The London markets are all held in early hours of the morning, so that the traffic from the market gardens could be carried out after the passenger cars had ceased running.

Water Power.—After remarking that the production of electricity for lighting purposes has hitherto depended principally on the use of steam power, the *Scotsman* says that there must be many small towns and villages in Scotland where its production by water power would be less costly than by the use of coal, and where electric light might be supplied at a less cost than gas. The water power of the country, which at present is for the most part allowed to run to waste, must sooner or later be economised in the interestof cheap production, and especially in the production of the electric light for the use of the smaller communities. In this direction a good example is being set in the Highland district of Lochaber, which has hitherto held anything but a forward position as an industrial centre. Foyers is outside Lochaber, but on its borders, and the Lochaber district is capable of furnishing water power immensely greater than that of Foyers, and none the less valuable because it can be applied at almost innumerable points and for a greater variety of industries. Some years ago the mansion-house of Achnacarry—Cameron of Lochiel's—was lighted with electricity, the power for producing which was obtained from the River Arkaig, the upper part of the Lochy. Inverlochy Castle, the residence of Lord Abinger, was about the same time supplied with electric light, the source of power being a small mountain stream, one of the Lochy's tributaries, and the use of the electric light in those neighbouring mansions suggested its employment for lighting Fort William. It may be added that this latter work, though a small affair, is not without some points of interest, and a brief description of it will be found elsewhere in our columns.

The Courage of Conviction. — It is frequently suggested that if members of local authorities were more enterprising in regard to the adoption of electric lighting, it would be better for their constituents. On the other hand, not so frequently, but yet sometimes, the town council goes in advance of its electors. Bury St. Edmunds, for instance, is a country town in West Suffolk that has been hit particularly hard by the prevailing agricultural depression. Down there, like Enid, their hoard is little, but their hearts are great. Nevertheless, when a majority of the Town Council proposed to light the whole of the streets with incandescent electric lights and to borrow £20,000 or more to do it, some of the ratepayers got a little alarmed. That being so, although the proposal for the Corporation to undertake the electric supply was carried by a majority, the town councillors who composed it now propose to form themselves into a company and do the work of electric supply at their own risk instead of that of the ratepayers. Whatever may be the financial result of the venture, it is impossible not to admire their courage, and the whole affair contrasts very well with what has happened at Bangor. There is a growing feeling that enterprises like light, water, or tramway work, which must necessarily be monopolist in character, are better in the hands of the municipality than of a private company. But when, instead of the company being an outside one, composed of shareholders living at a distance and having no care for the interests of the town, it is really made up of men who are or might be the town councillors of the borough, the objection to the private company system is greatly minimised.

Separation of Tellurium. — A method for the separation of tellurium from copper residues has been described by Mr. Cabell Whitehead in the *Journal* of the American Chemical Society. In the electrical refining of copper the washings from the gold residues contain the tellurium as tellurous oxide or sulphate. The tellurium may be obtained from these either by precipitation with copper or by passing sulphurous anhydride through the solution. It may be finally purified by distillation in hydrogen. When a solution of sodium tellurite is added to a solution of an ammonium salt a white precipitate of tellurous anhydride is thown down, which becomes granular on boiling. A small amount of tellurium or of some metal which can be precipitated by sulphurous anhydride remains in solution; this soluble portion is still under investigation. Potassium ferrocyanide does not react with tellurium chloride at once, but after a few hours Prussian blue is formed. When tellurium is heated with aluminium the two combine with explosive violence, forming a chocolate-coloured compound difficultly fusible, which has the composition of Al_2Te_3. It is hard and brittle, and can readily be ground to powder; when exposed to moist air it is decomposed and hydrogen telluride is slowly evolved; when thrown into water it is rapidly decomposed. Tellurium is readily deposited by an electric current either from an acid or alkaline solution. It has been found possible to separate tellurium from copper by adding an excess of sodium hydroxide and about three grammes of potassium cyanide for each gramme of copper present, and passing an electric current through the solution, when the tellurium is thrown down as a black, non-adherent precipitate, which can readily be filtered off; the solution can then be slightly acidified with sulphuric acid, and the copper estimated in the usual way by electrolysis.

"Cassier's Magazine."—The August number of this magazine contains several articles which will be of interest to the electrical engineer. An automatic coal weigher, for instance, is described by Mr. Francis H. Richards, and would be of great use to central-station men for keeping their coal records above reproach. There is one article, however, by Mr. G. S. Strong which we feel called upon to notice unfavourably. It is headed "The Future of Power Development." The author commences by stating the well-known fact that electricity is not a source of power, and then proceeds to devote a good proportion of his space to figures showing that it is not a good distributor of power. He starts with the assertion, to which the editor of *Cassier's* takes exception, that the cost of the works at Niagara has been so high that the power costs more than the corresponding cost of power in a coalfield district. The next amazing statement is that a locomotive generates power more economically than a stationary engine. The author

Digitized by Google

considers that the electrical generating plant takes nearly 4lb. of coal per horse-power, and that a locomotive can be made to work inside 2lb. It is the old method of comparing trial trip figures with average working costs, and such special pleading is useless. The author finally compares the cost of equipping a railroad electrically and the cost of steam locomotives. We are sure that there would be no difficulty in getting a contractor to undertake the work at his figure for electrical equipment, as one such contract would make his fortune. After appreciating the cost of outfit, the author proceeds to review the cost of working, on the assumption that the engines in the electric stations will require more coal than the locomotive. It is therefore quite a relief to proceed with him to a new subject, which happens to be that of gas-engines and gas-producers. We trust that the editor of the magazine will have an article in his next issue confuting some of the figures given. The biographical notes about Mr. C. F. Brush, of arc-light fame, and the paper by A. E. Childs on storage batteries for central stations, are also interesting reading.

Rontgen Radiations.—According to telegrams in the daily papers, at a psychological congress at Munich there has been a Röntgen ray demonstration, at which a "living human body (why not say a man and save two words of the telegram) was placed under the action of the rays," and observers were able to watch the action not only of the osseous parts of the body, but also of the diaphragm, stomach, and heart. How it was done is not said, except that it is mentioned that "specially prepared tubes" were used. Probably higher vacua than usual and an extra high voltage were adopted. In this connection it would be interesting to know what is the precise effect of using anodes of less density than platinum on the penetrating power of the rays and varying the nature of the residual gas in the tube. The latter ought to have a very considerable influence on the result, but it must be remembered that though theory may give some hints as to the way to get a particular kind of wave length, there is also the question to be considered of whether the fluorescent screen or the photographic plate will respond to it. Lastly, it has been gravely announced that a discovery has been made—and made in Germany, though not at Munich—that the aurora borealis is caused by Röntgen radiations emitted from the sun making the air fluoresce. That the aurora is seen at night does not seem to have occurred to the discoverer. It is really quite remarkable how a subject like the new radiations, which obviously required in anyone dealing with it some acquaintance with the conceptions of physics, should from the beginning have been selected as a happy hunting-ground for that numerous class of people who, being without clear ideas in the matter, are as fertile in suggestions as they are incapable of understanding the experimental proofs of their futility. But perhaps even this is not more remarkable than that the really eminent persons who interested themselves in the subject did not sooner see that phenomena which were as familiar to them as their alphabet were entirely fatal to the original hypothesis of longitudinal ether vibrations.

Grades on Tramways.—A summary of a paper by Mr. Foster on the subject of grades, which was read before the California Street Railway Association, has been given in the New York *Electrical World*. Mr. Foster discusses in general the ascending of grades, and gives brief descriptions of a number of devices used in the Pacific Coast cities where there are very steep grades. There has prevailed a misconception as to the power required by an electric car on a grade, as the speed does not remain the same on the grade as on the level. As the work to be done increases, the car speed decreases until the power is within the limits of the motors. Diagrams are given showing how the speed decreases up to 14·5 per cent. grades, as also a curve showing what the power would be if the speed remained constant. The motormen are usually instructed to use only the series notch on heavy grades, as it is more economical to run the motors in series than in multiple. This question Mr. Foster discusses, and finds that from the standpoint of the repair shop the series combination is the cheaper; from the standpoint of the power-house engineer it is also better, as the plant can handle twice as many cars as if they were run on the multiple notch. From the standpoint of the investor the series notch is also preferable for grades, lest the station capacity should have to be doubled; but from the standpoint of the watts per car mile, or the coal pile, the multiple notch is found to be slightly cheaper. The current will be more when in multiple, but the time will be less than in an inverse ratio to the current, or, in other words, the speed will be more than in a direct ratio to the current. This saving, however, is not worth considering, as it is undoubtedly more than counterbalanced by the disadvantages. Theory states that the amount of "power" (evidently work or energy is meant) required to propel a car up a grade is independent of the speed, for with greater speeds the time during which it is exerted is shorter. But there is a disagreement between theory and facts owing to the relative car efficiencies at the two notches, it being higher at the multiple notch. It is often asked what the steepest grade is that can be ascended—a question not easily answered. Mr. Foster states that it is not so much a question as to how steep a grade can be climbed as how steep a one can be safely descended. In San Francisco grades of 14·54 per cent. are operated successfully in both directions, and at Oakland 14·25 per cent. In Seattle a single-truck car climbed a grade of 16·85 per cent., 500ft. long, but the car was not allowed to descend it without an outside check on its speed. If the car is brought practically to a stop at the top of a grade and then let down at six or eight miles an hour, the danger of a runaway or flattened wheels is very slight. Some motormen use a method which allows them to descend rapidly with the brakes on, and yet not slide the wheels; this is done by putting the controller on the series notch while the brakes are set. The maximum braking effect is when the pressure is just under the skidding point; but the idea of using power while descending grades is the reverse of what engineers seek to realise. It may be argued that a car can be stopped more quickly by causing sliding wheels to rotate than by letting them slide, but in a test it was found that the pull per ton required to tow a car with the brakes set decreases from 42lb. to 5lb. as soon as the wheels slipped. It would be much cheaper, however, to allow the wheels to turn by slacking of the brakes than to do it by using the current. At Mount Lowe two cars are permanently attached to the opposite ends of a cable that passes around a winding drum at the top of a grade, and the force of the descending car aids the ascending one. In Fillmore-street, in San Francisco, there is practically a double track and the descending car aids the ascending one as at Mount Lowe, but the difference between the loads is made up by the use of motors. At Seattle there is a single track with a second one below it in a conduit; the descending car pulls up a load of pig iron as a counterbalance below, until it reaches a level track above; the next ascending car pulls the endless cable and thus starts the counterbalance down the grade.

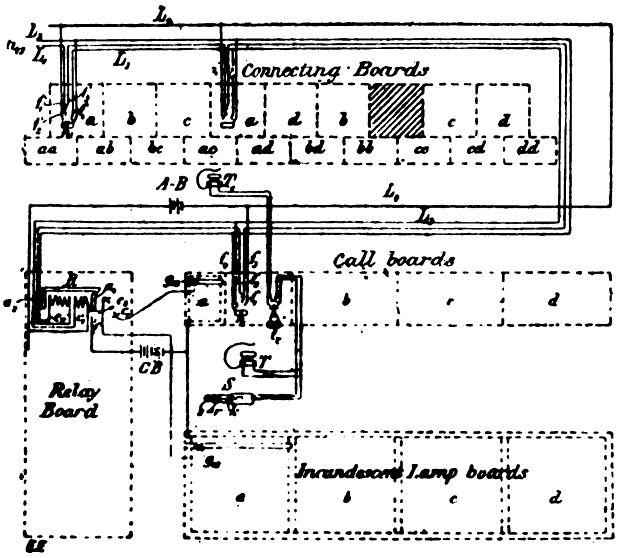

FIG. 2.

Fig. 2 represents the general plan of connections for an exchange with four groups. The equipment consists of the combination boards, on which the connections

and an incandescent lamp board, which optically indicates whether the wires are free or engaged. The double wire of a subscriber in group *a* are led first through two panels of a combination board, the switches for the outward line being connected in series, for the return line in parallel. From the combination board the wire runs to the callboard of group *a*, where it connects with a similar plug switch, and from here it goes to the call relay, R, in the relay-board. This relay is designed on the principle of the well-known self-erecting annunciators of the Western Electric Company. The front armature of this relay can assume three positions—the middle or position of rest, as shown; the drop position, in which spring *f* presses against the bottom contact, c_1; and the erect position, when spring *f* makes contact with c_2. In the drop position *f* closes the circuit of an incandescent lamp, g_{12}, mounted on the callboard, whilst in the erect position it inserts an incandescent lamp of the same number (g_{12}) mounted on the lampboard, which, as mentioned before, indicates optically for the whole exchange whether the subscribers' lines are free or engaged.

Besides the two telephone lines, L_1 and L_2, of the subscriber, there is a third line, L_3, commencing at the erecting coil, e_1, of the call relay, and leading to the contact springs, f_4, of all the switches of the respective subscriber lines. A further line, L_4, common to all the switches of the whole exchange, branches off to the spring, f_1, of the switches, and on the other side of the erecting battery, A B, to the various relays.

The mode of working is now as follows:

When the subscriber (*a* No. 12) calls up the exchange, the erecting magnet, e_2, attracts its armature, a_2, thereby releasing the front armature, a_1, which drops forward and

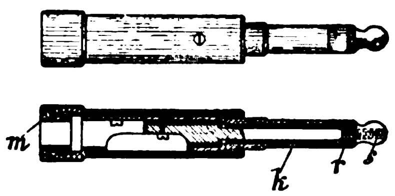

FIG. 5.

closes the circuit of lamp, g_{12}, on the callboard. The lighting up of this lamp is the call for the operator, and he now inserts a triple plug, S (connected to his telephonic instrument, T), into switch, k_{12}, thus switching himself on to subscriber (*a* No. 12) as the body of the plug, *k*, touches the cylinder, *h*, and point, *s*, the spring f_2, which it lifts off spring f_3. This cuts out the call electromagnet, e_2, of the relay from the telephone circuit, and the local circuit is being completed by means of erecting magnet, e_1, as the insulated ring, *r*, of plug, S, connects the springs f_1 and f_4,

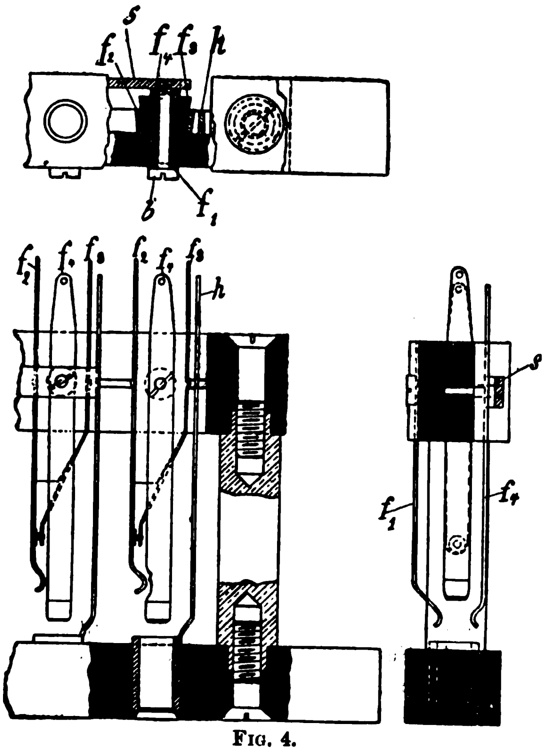

FIG. 4.

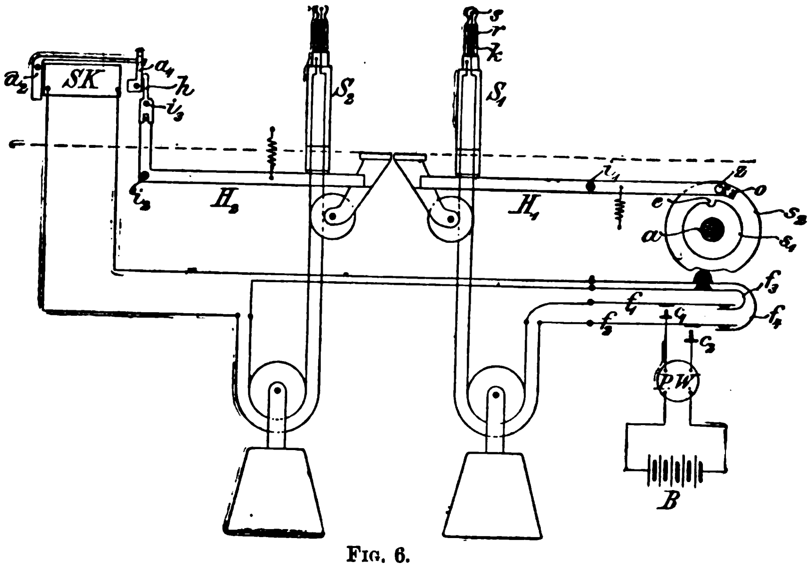

FIG. 6.

between subscribers are effected; the callboards, on which the subscribers' orders are received; the relay-boards, which contain the call annunciators (designed as relays);

thereby causing e_1 to attract its armature, a_1, and to interrupt the lamp circuit, g_{12}, on the callboard, in place of which lamp g_{12} on the lampboard is inserted. This lamp thus

Digitized by Google

burns as long as any switch of the respective connection is plugged and shows that wire *a* No. 12 is engaged.

After having inserted his plug the operator replies as usual, "Here, central" and receives from the subscriber the number of the desired connection—for instance, *b* No. 209; he now glances beyond his board at the lampboard to see whether the wire is free or not—that is, whether lamp 209 in panel *b* is burning. In this case he answers, "Wire *b* 209 engaged" and withdraws his plug, whereby the local circuit of the electromagnet e_1 becomes interrupted, armature a_1 turns forward until arrested by the drop lever in the position illustrated, and lamp g_{12} on the lampboard of course ceases to burn.

If, however, line *b* No. 209 is free the operator has to transmit the order to the operator on the combination board; for this purpose his table contains a number of keys, by means which he can put himself in telephonic

The following points are therefore of importance when determining the size of the groups: (1) the number of simultaneous connections during the busiest hours; (2) the number of simultaneous connections which an operator can manage during the average duration of a conversation. It is not possible to alter the first figure by constructive considerations, but the second figure depends to a very considerable extent upon the design and efficiency of the system. This is an inducement to make the manipulation of the connecting cords as simple and speedy as possible. This has been attained in the present system by effecting some manipulations, which are required at each connection, at the proper moment and without help of the operator, simply by automatic mechanism, so that the operator has simply to insert and withdraw the plugs, and is therefore enabled to attend to 30 pairs of plugs.

Takin' this figure as our basis, we arrive at the size of

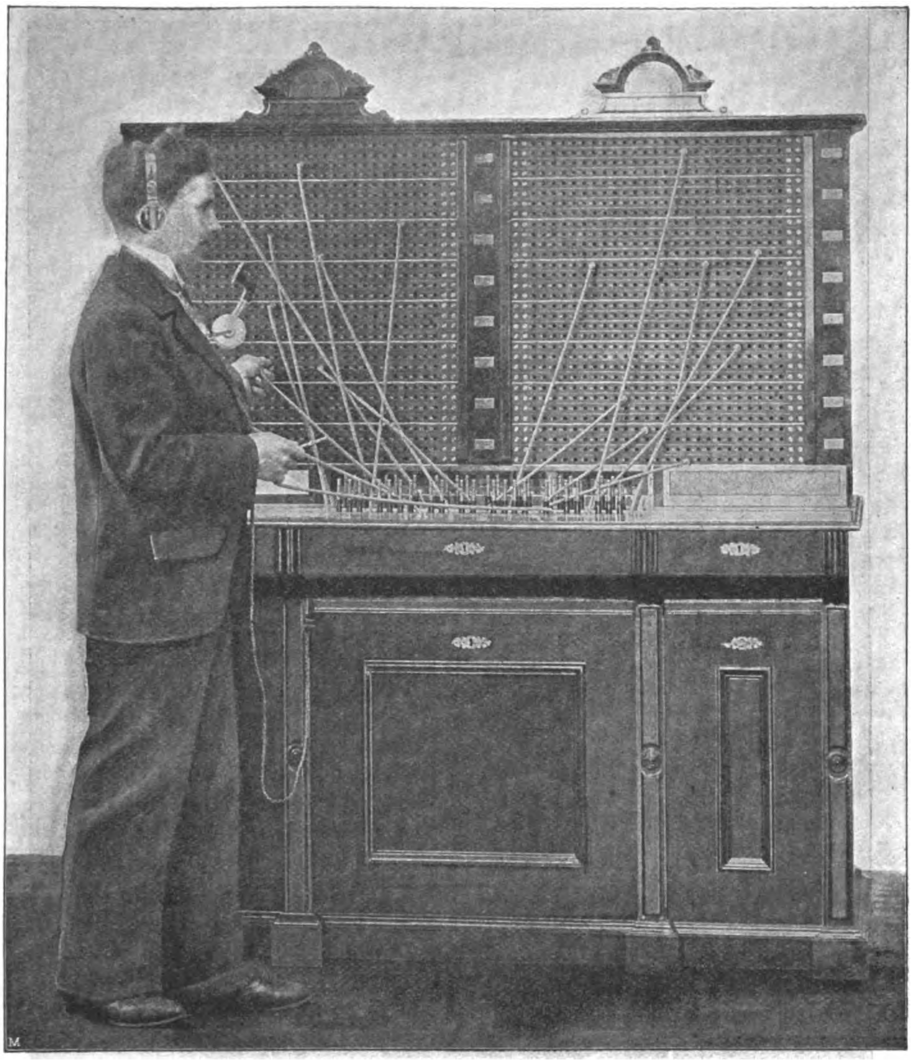

FIG. 3.

communication with those operators who are able to effect combinations with his group (*a*)—namely, *a a*, *a b*, *a c*, *a d*; the respective keys are marked *a b c d*. In this instance he presses key *d*, marked t_d in the figure, and simply gives the order, "*b* 209 with *a* 12," whereupon the combination operator at once connects the two corresponding plugholes by means of a double cord; at the same time the respective relays are cut out of the speaking circuit, and the proper lamps on the lampboard begin to burn. On receiving the disconnecting signal the connection is withdrawn, and the lamps become extinguished.

As is obvious, the groups ought to be made as large as possible, for the larger they are the smaller will be their number, and the smaller the number of necessary switch-panels. The number of subscribers in a group must, however, be selected with a view of enabling the operator on the combination board to manage all the connections between two groups.

the groups as follows: For an exchange with 10,000 subscribers and frequent calls about 1,300 cords are required (inclusive of the necessary reserves) in order to cope with the calls during the busiest hours of the day. If we subdivide the whole of the 10,000 subscribers into 10 groups of 1,000 subscribers each, we require according to the system of combination 44 working places, which, with 30 cords for each, give 1,320 cords, this number being sufficient to deal with the connections, so that the sub-division is practicable. Of course, this figure varies according to special circumstances; generally speaking, it varies between 700 and 2,000 subscribers per group, the higher figures being resorted to for large systems, as, on the whole, the increase of calls does not keep pace with the growth of the system, but lags somewhat behind it.

The experimental equipment here to be described contains 800 subscribers in each group. Fig. 3 shows the first combination board, *a b*, which corresponds to the first

Digitized by Google

working place of the row; it contains 30 pairs of plugs on the plug-board, and the illustration shows the two switch-panels, *a* and *b*, with 800 switches in each. The dimensions are determined by the width necessary to ensure the free movement of the operators standing side by side; it has been fixed at 65cm. (26in.), which size, together with the small number of switches per panel, allows us to place these a fair distance apart, which, from a technical point of view, is essential. The switch-rows, containing each 25 switches, are separated by narrow strips of yellow wood, and the groups of 100 switches by wider white strips, facilitating the location of the plugholes.

Fig. 4 gives the construction of a switch-row in detail; the only loose contact has vertical springs, f_2 and f_3, with platinum contacts, which are, moreover, rubbing contacts, since f_3 is elastic, so that contact irregularities are guarded against as far as possible; bar *s* corresponds with wire L_4 in Fig. 2.

Fig. 5 shows the plug in detail, and requires no special explanation.

The automatic arrangements mentioned above consist of a simple lever gear, which automatically raises the annunciator flap, and of a switching gear, which comes into action the moment a plug is raised for making a connection, and which, for the space of four seconds, sends a call current into the subscriber lines.

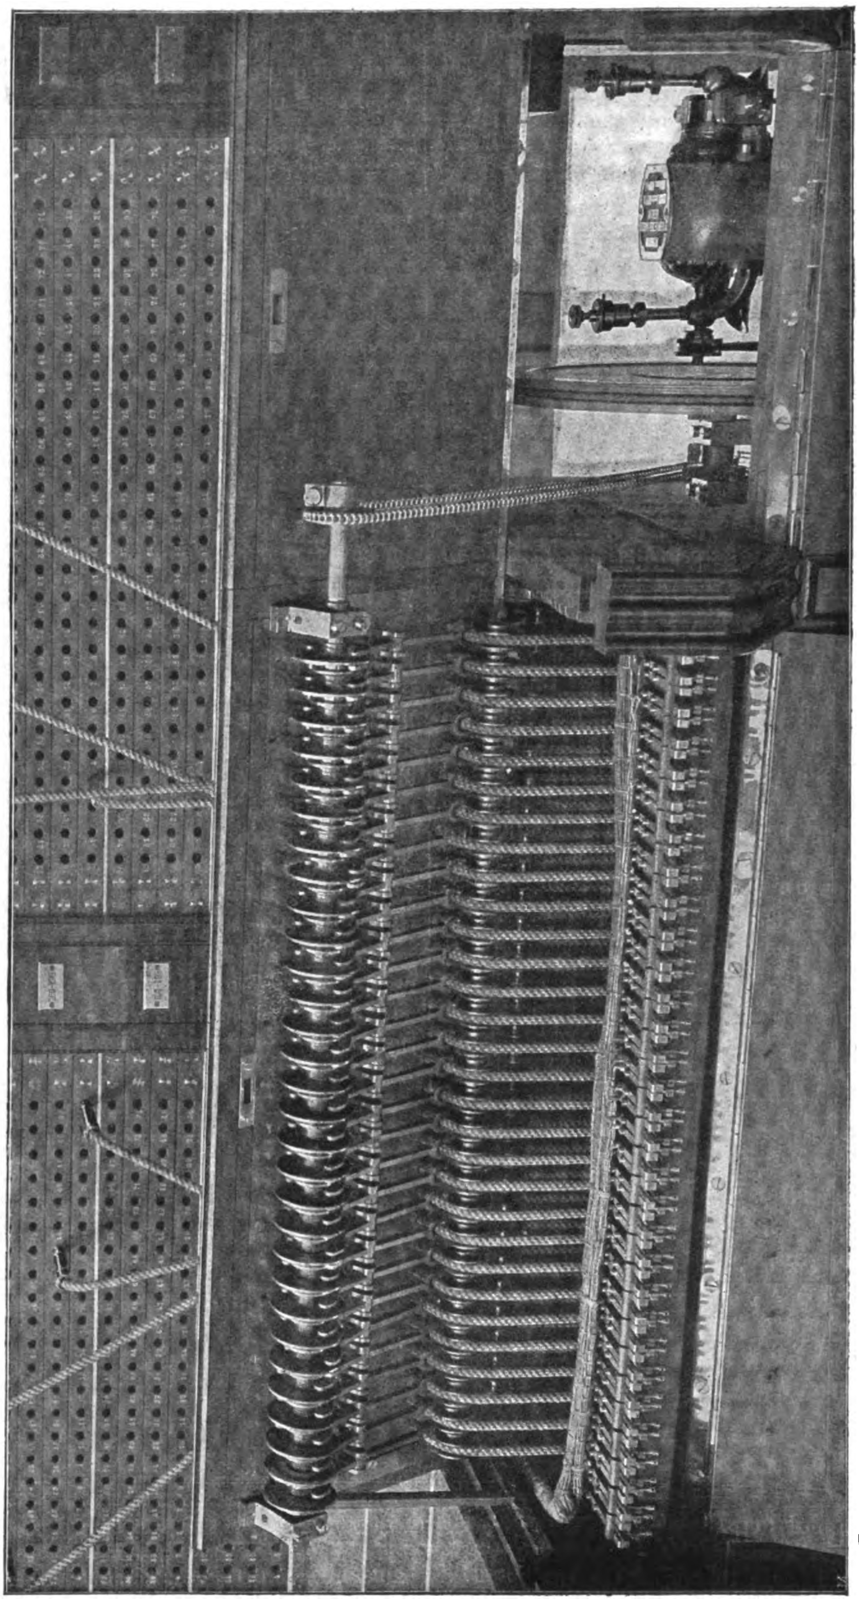

Fig. 7.

These two mechanisms are sketched in Fig. 6. The front plug of a cable rests on a double lever, H_1, with a fulcrum, at i_1, bearing on its outer (right side) end a pin, *z*; on the spindle, *a*, which is kept in slow rotation from a small motor (making one revolution in about five seconds), the two discs, s_1 and s_2, firmly connected together, are placed

Digitized by Google

so that they tend, by friction on the spindle, to turn with it. As long as H_1 remains in the position shown, this tendency to revolve is counteracted by the knob, *o*, on disc s_2 bearing against pin, *z*, but on lifting the plug S_1 the lever, H_1, swings round *i*, pin, *z*, going down until it touches against the flange of disc s_1, so that knob, *o*, is disengaged, and allows both discs to follow the rotation of the spindle, *a*, at the same time depressing the contact springs, f_4 and f_3, and effecting electrical contact between f_1 and f_2 and the battery contacts, c_1 and c_2, and simultaneously breaking the connections between f_1 f_3 and f_2 f_4; plug S_1 has meanwhile been inserted in the plughole of the subscriber wire, and battery, B, sends now a call current into it (through the pole-changer, P.W.) for about four seconds, until the discs have turned so far that the insulating piece between f_3 and s_2 drops again into the groove of s_2, re-establishing the connections as sketched; a moment later groove *e* engages with pin, *z*, arresting discs, s_1 s_2. At the termination of the conversation the plug drops back on lever, H_1, lever, *h*, pivoted in i_3, which gears into H_2. If S_2 is raised, the right end of H_2 swings upward and the upper end of *h* to the right. On receiving the termination signal, annunciator, a_2, is released, turns forward until stopped by *h*; when S_2 is pulled out of the switch it falls back upon H_2 and turns this, *h*, and a_2 back into the initial position.

The callboard (Fig. 8) is divided into working places of 200 subscribers each, containing a lampboard with 200 incandescent lamps, and below this a switch-panel with 200 plugholes; besides, there are on the left of each switch-panel three keys for the speaking lines to the three combination boards, *a b*, *a c*, and *a d*.

The lamps are arranged 20 in a row, and covered by brass thimbles, the front ends of which are closed by dark-green glass discs. The back of each disc is thickly painted over with matt white paint, in which a number is cut out, backed by a disc of white parchment paper; with this arrangement the number is invisible when the disc receives front light, but appears, however, green against a dark back-

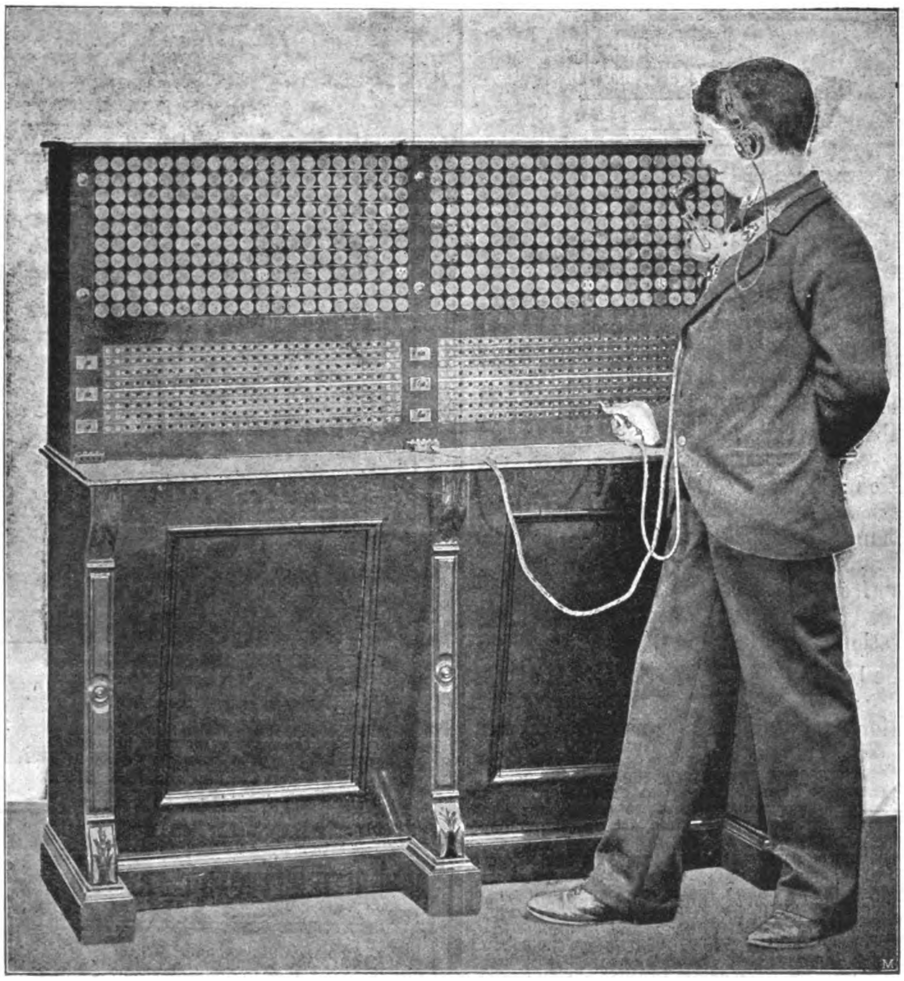

FIG. 8.

turning it back to its initial position, making discs, s_1 s_2, free again to turn until *o* presses against *z*.

Fig. 7 illustrates the constructive details of this automatic mechanism; it represents the combination board with the plugboard opened; on the right side is the small shunt motor, which slowly turns the spindle, *a*, by means of a double cord transmission and chain-wheel. This spindle carries the 30 discs for the 30 cables, and is supported by two bearings, which, with the fulcrums of the 30 switch levers, are fixed to a metal plate screwed to the underside of the plugtable. Instead of the friction arrangement as above sketched, the discs are geared by the help of the lever to the spindle through simple toothed wheels. Of the loose cables, the contact parts marked f_1, f_2, f_3, and f_4, as well as c_1 and c_2, and their wires, are visible. In order to ensure the smooth and undisturbed movement of the pulley weights, partition walls of sheet iron have been inserted between these.

The raising mechanism of the annunciator flap, S K, consists of a lever, H_2, turning round spindle, i_2, and of a small ground when the incandescent lamp burns, the white paint being opaque to the light.

The 20 lamps of each row are fixed on a common iron bar, S (Fig. 9), which through rail *r* (common to the 10 rows of lamps) communicates with one pole of the battery. A so-called "attention lamp" is also switched in circuit, and lights up whenever one of the 200 subscriber lamps is inserted into circuit. The operator, therefore, does not need to watch the whole lampboard, as the attention lamp indicates when there is a call. This is of special advantage when one operator has to attend to several working places during the quiet business hours or during the night. Behind the iron bar is fixed a wooden beam, L, supporting the connecting springs, *f*, for the centre pole of the lamps. The protecting thimble, R, fixes on to the metal socket of the lamps by means of a bayonet fitting, and can be easily removed from the front should it become necessary to replace a lamp, and as the lamp voltage is but four volts the thimbles may be safely handled.

As speaking instruments the operators use a head tele-

Digitized by Google

phone and chest microphone (see Figs. 3 and 8) of the Ericsson pattern. It allows great freedom to the movements of the operator.

The incandescent lamp board (Fig. 10) is sub-divided into panels of 100 lamps each. Of the eight panels only four are fitted, and of these three are provided with white and one with green number glasses, the latter of which appears to be of greater advantage. The design is the same as in the lamps on the callboard.

The relays of each group are arranged in a glass-fronted double cupboard, so that the dust is kept from the contacts, as will be seen from Fig. 11. Ten relays are mounted on a board, which slides out, the connecting wires visible in the illustration being in reality replaced by spring contacts on the inside of the backboard, so that the relay-boards

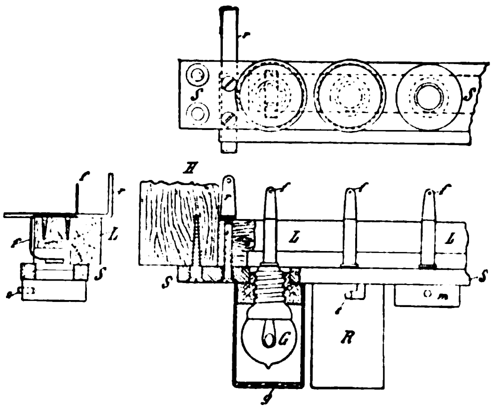

Fig. 9.

may be exchanged within a few seconds; the cables are carried along the outside of the cupboard back.

The work of the operators is now as follows:

A.—If the desired subscriber wire be engaged.
On callboard *a*.

1. First manipulation: plugging the switch of calling subscriber 12.
2. Report: "Exchange, here." Receiving the desired number b_{15}. Examination by looking at lampboard whether b_{15} be free. Answer to caller, "Wire b_{15} engaged."
3. Second manipulation: withdrawing plug 12.

B.—If the desired line be free.
On callboard *a*.

1. First manipulation: plugging the switch of calling subscriber 12.

3. Second manipulation: pressing key *b* and reporting to combination operator, *a b*, "b_{15} with a_{12}."
4. Third manipulation: withdrawing plug 12.
On combination board *a b*.

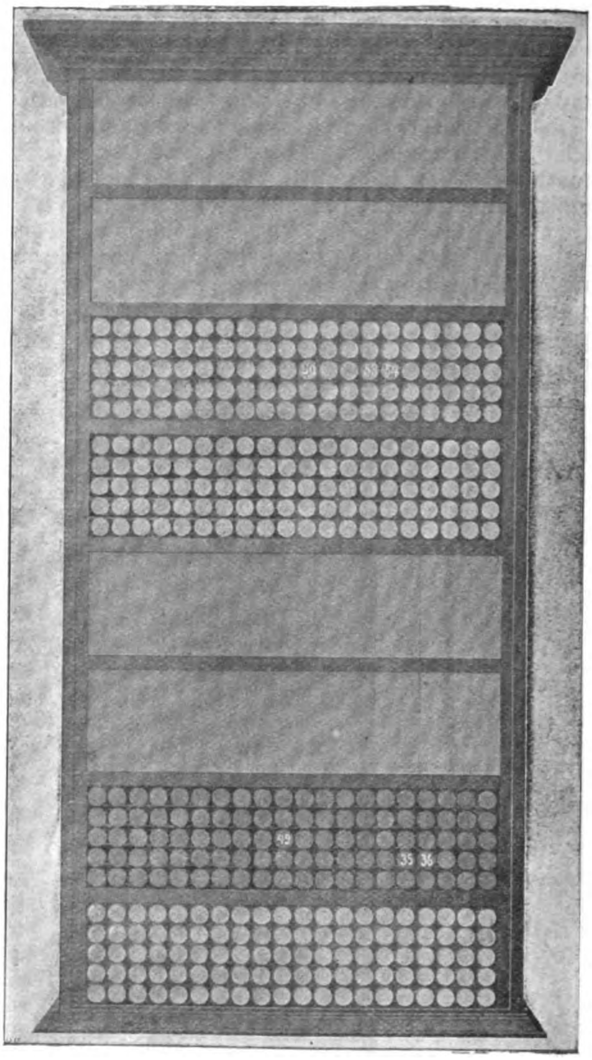

Fig. 10.

5. Fourth manipulation: plugging switch b_{15}.
6. Fifth manipulation: plugging switch a_{12}.

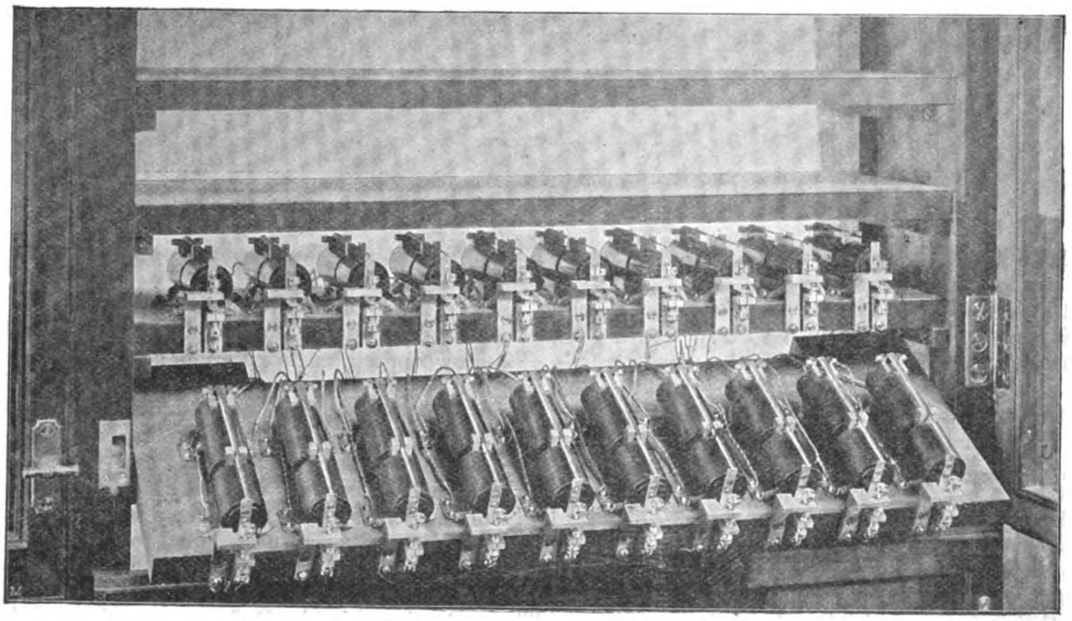

Fig. 11.

2. Report: "Exchange, here." Receiving the desired number b_{15}. Examination by looking at lampboard whether b_{15} be free.

7. Sixth manipulation: withdrawing plug a_{12}.
8. Seventh manipulation: withdrawing plug b_{15}.

During hours of great pressure the manipulations of the

Digitized by Google

call operator A_3 and A_1 for the following call are effected together, likewise B_4 and B_1, so that the work, if the wire be free, is reduced to six manipulations for effecting and interrupting a connection, and to one manipulation if the wire be engaged.

At the same time there is a check for the proper execution of each manipulation. If a wrong hole is plugged at A_1 and B_1, then the call incandescent lamp will continue to burn, drawing at once the operator's attention to the mistake, instead of necessitating the usual waste of time by calling repeatedly in the wire, "Here, exchange."

During manipulation B_3 the subscriber remains in circuit, and thus, hearing the transmission of his order, may, of course, check the correctness of same, and eventually may call "wrong" and repeat the proper direction. The call operator can also check the manipulation b_{15} with a_{12} on the combination board, for in the case of proper handling b_{15} lamp must light up in the lampboard, and a_{12} lamp, which is already alight, must continue to burn when he withdraws his plug from switch a_{12}.

The groups have up to now been denominated by the letters of the alphabet, but as consonants like *b p w*, *m n*, *d t c* are difficult to distinguish by telephone, they have been replaced by short, crisp names beginning with the respective letter.

As regards the arrangement of the equipment, it stands to reason that only the lampboards and the callboards need be in the same room, the other instruments being placed wherever convenient. In larger exchanges it would be advisable to provide a room for the callboards, incandescent lamps, and relays, and another room for the combination boards.

In an exchange for 40,000 subscribers the callboards require a hexagonal room of about 20 yards diameter; these boards are placed in four rows running parallel with the walls, so that each row rises towards the centre of the room about half a yard against the outer one. The operators turn their backs to the centre of the room, and have thus a complete and uninterrupted view of the walls in front of them, which are covered by four complete lampboards in such a way that each board with 40,000 lamps covers 1½ walls. (There are thus four lamps in each circuit to indicate the state of the subscriber wires.) With this arrangement the greatest distance between operator and the farthest of his lamps is only 10 yards, so that the numericals are easily distinguished.

In the formula given for 20 groups we require 211 work places, each of which, with 30 cable pairs, gives 6,330 pairs, this number being sufficient for 40,000 subscribers, even making provision for an increase in the work, so that we have 2,000 subscribers per group.

The combination board represented by the table requires a room of about 20 yards by 22 yards if we take away the places to the left of the vertical line and place them as indicated below, so that they fill the vacant space at the bottom.

i	*a*	*k*	*b*	*l*	*a*	*m*	*b*	*n*	*a*	*o*	*b*	*p*	*a*	*q*	*b*	*r*	*a*	*s*	*b*	*t*	*a*	*u*	*b*	*b*

The other rooms required are small, and are chiefly confined to the accumulator-room, as the relay cupboards may be placed below the lampboard in the callroom.

This economy of space compares favourably with the space required for exchanges on the multiple system. As regards the cost of the equipment, it may be mentioned that for one exchange of 40,000 subscribers it comes out cheaper than for seven exchanges on the multiple system—namely, five exchanges of 6,000 subscribers each, and two exchanges of 5,000 subscribers each.

The number of switches for the new system would be barely 500,000, as against 2,500,000 for the seven smaller exchanges; the number of simultaneously working operators 411, as against 1,000 to 1,200 on the multiple system, if we base our calculation upon the division of working places as at present in force at Berlin—namely, 66 to 67 subscribers, or 10 to 12 combination wires per operator.—*Elektrotechnischer Zeitschrift.*

ALTERNATE-CURRENT TRANSFORMERS.*

BY DR. J. A. FLEMING, F.R.S.

LECTURE III.

(Concluded from page 162.)

One thing that should be noticed in connection with this part of the subject is that the iron core losses in the transformer are diminished as the transformer heats up. The curve in Fig. 42 shows the results of an experiment with a 50-kilowatt transformer. The transformer was taken up when perfectly cold, and its core loss was measured and found to be 983 watts. This transformer was then connected with the circuits, and the core loss was taken at various intervals during a period of 20 hours until the transformer had reached a final constant temperature. It was then found that the iron core loss had fallen to 893 watts. The transformer was then disconnected from the circuit and allowed to cool, observations being taken during that period. After 24 hours the transformer had again become quite cold, and the core loss had risen up to 983 watts. There is, therefore, a difference of 100 watts, or nearly 10 per cent. in the core loss of the transformer when taken hot and when taken cold. This experiment shows the necessity for defining the conditions under which the core loss and efficiency of a transformer shall be taken. It is not enough to specify simply that the efficiency shall be of a certain value. It must be specified under what conditions this efficiency is to be taken, whether with the transformer cold or the transformer warm. In addition to this, there is a variation of the iron core loss taking place with time.

Variation of Core Loss of a 50-K.W. Transformer with Temperature.

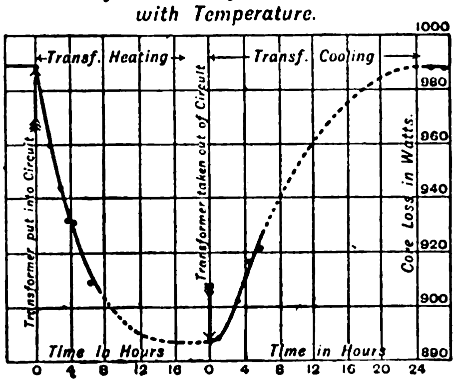

FIG 42.

When a new transformer which has never before been used is connected with the circuits, it is often found that when core loss measurements are made continuously at regular intervals, the core loss goes on increasing, and this may take place to the extent of 40, 50, or even 100 or more per cent. increase. In fact, instances have been noticed in which a core loss has increased in the course of a course of a few months to three times its original value. Mr. Mordey found that he could produce this effect in iron by slow heating. It does not occur in all transformers. In an experiment I specially tried with two new Thomson-Houston 30-kilowatt transformers, which were connected to the circuits night and day for three months, and regularly measured at intervals, no apparent increase in the core loss was found. The reasons for this permanent increase in the hysteresis loss are not yet entirely explained. In the case of some iron which has been very carefully annealed, it is found there is a remarkable rise in the hysteresis loss when this iron was used as the core of a transformer. The same rise is also found in the case of iron which has not been very carefully annealed. We cannot at the present moment state precisely what are the conditions under which this increase in core loss takes place, or what is the constituent in the iron that tends to produce it. It has been supposed by some investigators that the presence of silicon in the iron has a tendency to determine this increase in the hysteresis loss, as the iron is magnetically used. It, however, points to the necessity not only of testing transformers at first when they are purchased and before accepting, but of taking a series of tests of the transformer at regular intervals. Suppose that in a sub-station there are three or four large transformers,

* Cantor lectures delivered before the Society of Arts.

Digitized by Google

and that one of these transformers is made the master transformer and is kept connected with the circuits night and day, the others only being switched on during the time of heavy demand; then it is obviously a very important matter that the transformer which is thus made the master transformer should be the one which has the least core loss; and if it should happen that this transformer is one which has largely increased its core loss by use, then it should be exchanged for another which has the least obtainable core loss for that size of transformer. In every sub-station the wattmeter arrangement described at the beginning of this lecture should be capable of being set up in order to make core-loss measurements in a systematic manner. It is perfectly clear that if a few thousand Board of Trade units more than necessary are being wasted in each transformer sub-station, that the total value of these Board of Trade units when added up and capitalised may realise a very considerable sum of money.

Sumpner's Differential Method of Testing Transformers.

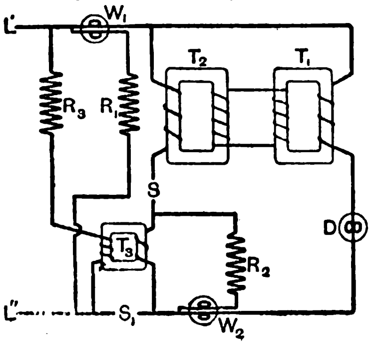

FIG. 43.

For the purpose of testing large transformers in workshops without requiring a large consumption of power, Dr. Sumpner has devised a differential method of testing, the arrangements of which are shown in the diagram in Fig. 43. In this case the power given out by one transformer on the secondary side is put back into the primary circuit by means of another reverse transformer, so that what is actually taken from the primary mains is merely the total loss in the two transformers. This total loss is measured by a wattmeter arrangement, which enables us to measure, therefore, the efficiency of the two transformers taken together, and therefore, if they are identical, the efficiency of either of them. In addition to the efficiency tests, there ought always to be a series of security tests to test the strength of the transformer. In the first place, the temperature should be taken after the transformer has been connected to the mains for 24 hours on open circuit, and then connected to the mains for two hours on full secondary load

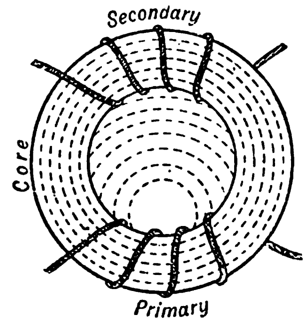

FIG. 44.

This temperature is best taken, as described in the beginning of the lecture, by measuring the resistance of the copper circuits, but it may be checked by means of a thermometer placed inside the case. Under no circumstances should the temperature in the interior of the transformer rise above 100deg. C. In the next place, electric pressure equal to double the primary pressure ought to be put on between the primary and the secondary circuits for at least 15 minutes, and the same double pressure ought to be put on between the primary and case—that is to say, if the transformer works at 2,000 volts on the primary circuit, 4,000 volts should be put on between the primary and secondary circuit for 15 minutes, and 4,000 volts between the primary and case for 15 minutes. In addition to this, the transformer should be tested for several hours at the normal pressure before being put to work. In the case of large transformers which have stood idle for some time it is not wise to put on the full primary pressure at once. The transformer should be gradually warmed up by passing a large current through the secondary circuit of the transformer, the primary circuit being short-circuited. In that manner the transformer will be gradually heated up, any moisture which has been absorbed into the insulating material or into the case will be got rid of, and the transformer will be gradually brought into a condition of high insulation. Transformers which have been standing in the stores for long time may frequently fail if put suddenly on to the working circuits without some such precaution.

Next, with regard to magnetic leakage, it is important to employ some test to ascertain whether there is a large magnetic leakage. Magnetic leakage, as already explained, is due to an escape of induction, linked with the primary circuit, and which does not entirely pass through the secondary. It is promoted by any separation of the primary and secondary coils, as in Fig. 44, but is not entirely eliminated by any arrangement of them, as may be seen by considering the diagrams in Fig. 45. This leakage, of course, can be ascertained by measuring the secondary drop as described above, and comparing that value with the total copper drop as calculated by the rule already given. An experimental proof of magnetic leakage can be obtained by a simple method due to Mr. Mordey. Two thermometers are taken, one filled with mercury and the other filled with alcohol. These thermometers are

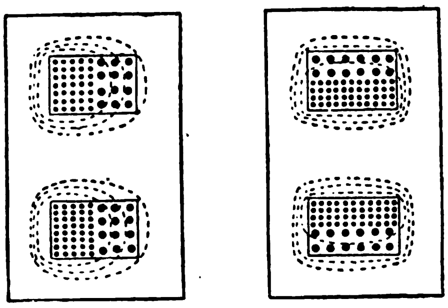

FIG. 45.

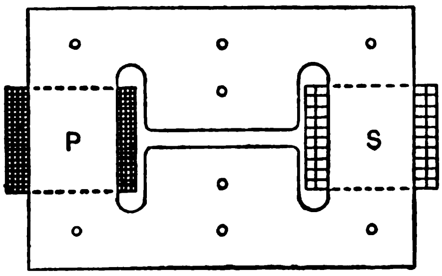
compared to see that they are in agreement at the ordinary temperature. The bulbs of the thermometers are then introduced into any portion of the transformer near the secondary coils and kept there for some time. If there is any leakage of magnetic induction outside the secondary circuit, this induction passing through the mercury thermometer will generate heat in the mercury and cause the mercury thermometer to rise, but the spirit thermometer will be unaffected by this process. Hence, although both thermometers will rise from external temperature, if the mercury thermometer rises more than the spirit thermometer it indicates the presence of magnetic leakage at that spot where the bulbs are placed. In some transformers a magnetic leakage is actually encouraged. A transformer, designed by Elihu Thomson, intended to give constant currents from the secondary circuit when the primary circuit is worked off a constant-potential circuit, is constructed as shown in Fig. 46. In this case there is a kind



Thomson-Houston, Constant Potential to Constant Current, Transformer.

FIG. 46.

of iron bridge interrupted by an air-gap across the core between the primary and secondary circuit; and across this bridge, or air-gap, induction is forced as the secondary current increases. This leakage, therefore, diminishes the E.M.F. in the secondary circuit, and that effect tends to keep down the secondary current, and hence to preserve it at a constant value. Such a transformer can therefore be employed to work arc lamps in series off a constant-potential primary circuit. The secondary drop is found to be affected to some degree by the nature of the alternators on which the test was made. A peaked primary E.M.F. curve gives a greater leakage drop than one with a more rounded from. In general, however, magnetic leakage is a thing to be discouraged, and every specification for transformers ought to contain a clause defining and limiting the amount of secondary drop. One convenient way of doing this is as follows: Suppose the standard secondary E.M.F. to be 100 volts and the primary E.M.F. 2,000 volts, then the specification should define that when the transformer is working on a constant-potential primary circuit of 2,000 volts, the secondary terminal potential difference on the transformer should be 100 volts at half load. At full load the secondary potential

Digitized by Google

difference should not be less than 98½ volts, and at no load should not be greater than 101½ volts. In this manner the unavoidable secondary drop is, as it were, distributed half up and half down, and is not so much felt on the lamps as if the transformer gave its standard E.M.F. at no load, and then experienced the full effect of the drop when loaded up to full load. Also in a specification for transformers the manufacturer ought never to be allowed to produce a high efficiency at the expense of a large secondary drop, but such a definition of the core loss and copper loss ought to be given that he is bound to produce an all-round excellence. As a sort of guide to the kind of figures which may be obtained by good makers in actual practice, the following table may be taken as representing the secondary drop and core loss in transformers of these various sizes. These figures may be taken as a kind of indication of the core loss and secondary drop, which can be obtained in good modern practice in the construction of transformers. Some makers may be prepared to do better than this; but exceedingly small iron core losses ought always to be looked upon with a certain amount of suspicion, the important question being, not how low can the iron losses be made at first, but how long will they keep low when the transformer is being used; and this, as above stated, can only be determined by careful tests, made at intervals, as the transformer ages.

Size of transformer defined by full secondary output in watts.	Allowable iron core loss on open secondary circuit in watts.	Allowable secondary drop in per cent. of normal secondary E.M.F.

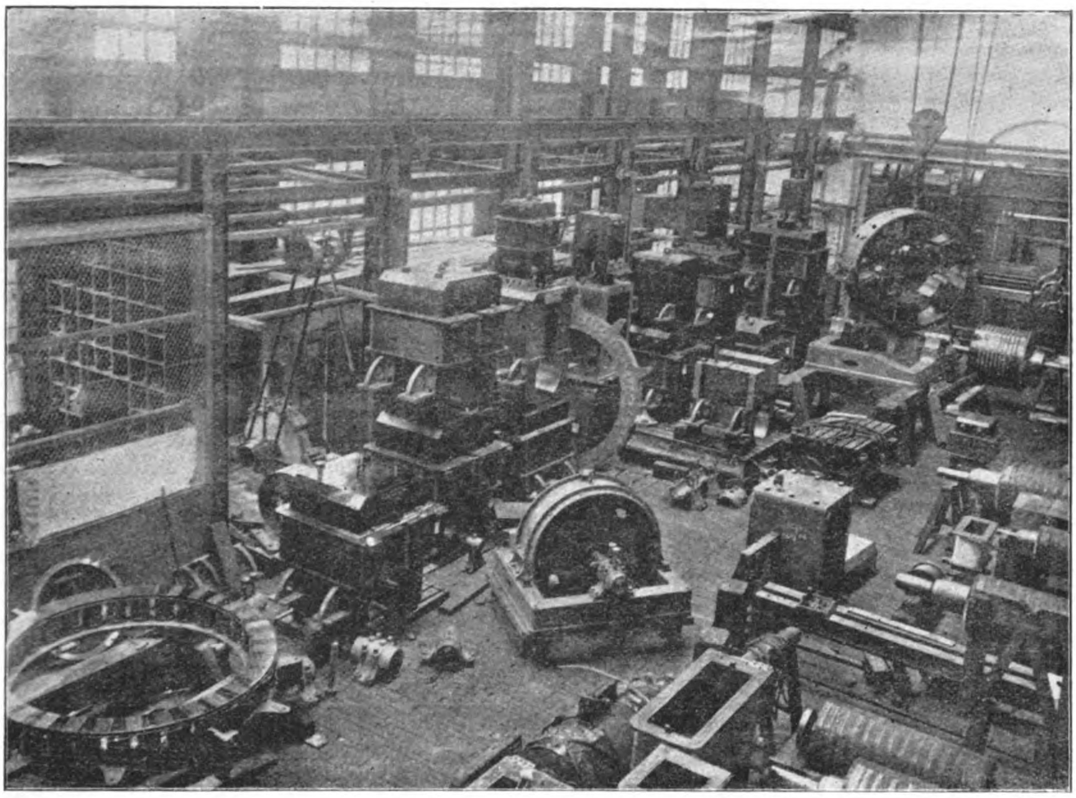
MESSRS. SIEMENS BROS. AND CO.'S ERECTING SHOP.

We have referred several times in our columns to the remarkable number of orders booked by the above firm in the first months of the present year. Both the quantity and the average size of the dynamos ordered were above any previous record of an English firm. We understand that the machines ordered are now all well on towards completion, and as several of the customers are unable to accept delivery the erecting shop of the firm presents a remarkable appearance. We are able to give some idea of this from our illustration, but unfortunately the dimensions of the dynamos and alternators cannot be accurately gauged from it. The usual practice of standing a 5ft. nothing man in the background has not been adopted, but the height of the table of the planing machine will give some idea of the sizes to the workshop engineer. Examples of all the types of electric generators made by Siemens Bros. are included in this view. The circular frame at the left of the illustration is one-half of the magnet field of an alternator of the original Siemens type, which has no iron in its armature. Another type of alternator, with stationary armature and revolving field, is seen in the centre of the foreground. The six large two-pole dynamos on the left, which are piled one above the other, are all from 350-h.p. to 400-h.p. machines, for coupling to high-speed engines. The front machine in the second layer is a 400-h.p. one, and is going to the station of the Charing Cross and Strand Electric Lighting Company. Other two-pole dynamos of



Siemens Bros.' Erecting Shop, August, 1896.

the same output, and some smaller ones, can be seen ranging down that side of the shop. At the further end a six-pole magnet field is shown. This is the first large direct-current multipolar dynamo manufactured by this firm, and it is intended to give about 600 h.p. It is, with its fellows, being supplied to the order of the Bradford Corporation. The armature of this dynamo is placed at the right-hand side of it. It is worthy of note that the above firm, whose two-pole dynamos up to 400 h.p. have gained such an enviable reputation for non-sparking and cool running, have adopted a multipolar design for a large size. We gather from this that the firm recognise a limit to the possibilities with two dynamos, although they set the limit of output much higher than many other designers. It will be interesting to note whether these Bradford machines will not initiate a change in the general practice in favour of multipolar design, on the ground of economy in first cost.

We have always considered that the multipolar machines in England have not had a fair trial, but have been judged by early types with cast-iron fields. The possibilities with the cast steel now available are very different to those in the close of the eighties, and we believe that the record of a few good multipolar machines would do much to turn the favour of the consulting world towards the less expensive types.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 11d.	9s. 9d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XVI. of new series of "The Electrical Engineer" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

INTERFERENCE.

In our last issue we gave the gist of the answer of the President of the Board of Trade to a question of Mr. Elliott Lees relating to electrical railways. The particular subject of the interference of one electrical undertaking with another electrical undertaking has only been partially discussed and settled, but with the greatly increased number of such undertakings the subject is rapidly becoming ripe to be settled as a whole. The ordinary law of the land is sufficiently complex to tax all the powers of the ablest lawyers who study it all their lives, and is not to be understanded of the multitude. Hence, it is with some fear of being wrong that we venture to say one broad idea seems to underlie all our law, to the effect, as is often said, "possession is nine-tenths of the law." The first comer seems to us to stand legally upon quite a different footing to all followers. So far as electrical matters are concerned, this seems to be the view of those who have hitherto had occasion to investigate matters. Up to the present the most important cases investigated have been in connection with telegraphy and telephony as interfered with by electric light or by electric traction mains. Telegraphic lines and telephonic lines were in operation before the Deptford station was built or the Leeds tramway to Roundhay projected. The Government on the one hand, and the Telephone Company on the other hand, were successful in their contention that the other electrical undertakings interfered with the due working of their undertakings, and the new comers, so far as we recollect, had to take all precautions to prevent such interference. At the time of the Leeds discussion we pointed out that the first comer might be in a far better position to prevent interference from the second, and at a far less cost than the second could be in preventing interference. Let us, however, assume a simple case. The first comer has an open field—he starts some electrical work, no matter of what kind. Naturally, he does his work at the lowest possible cost and without any provision for future interference. Thus, if possible, he will use earth returns and not metallic returns, because the latter, though preferable for many reasons, are more costly, and under certain conditions earth return is perfectly satisfactory. Now, the new comer commences operations—uses heavier or different currents, and also attempts to use earth returns. The result may be disastrous to the first undertaking, but the compulsion upon the second comer to use metallic returns may increase his outlay beyond the point of possible remuneration, or involve him in an expenditure far and away greater than it would the owner of the first undertaking to put his work into such a position that the interference of the second is impossible. According, however, as we read the law and the Board of Trade regulations at present, the first comer has the prescriptive right to the use of earth to the detriment of all future operators. Carry the matter further. Assume that you have installed an electric light undertaking upon the continuous-current system, and that a heavy railway is to

Digitized by Google

be run by an electric system—an alternate-current system for preference. Will there be any interference if the first comer has not provided against such a contingency? If there is interference, who is to be at the expense of putting an end to such interference? The Board of Trade have issued regulations which may be satisfactory so far as telegraphy, telephony, and electric lighting are concerned, or so far as telegraphy, telephony, and electric traction are concerned, but as yet there are no regulations which take into consideration the action of traction mains upon electric lighting mains, or *vice versâ*. This seems to have been the point raised by Mr. Elliott Lees and answered by Mr. Ritchie. This answer indicates that the Board of Trade will issue regulations concerning these interferences, and we have to point out to those interested that the time for making representations to the Board of Trade is before these regulations have been issued, and that criticism after their issue will be of little use. In many instances the grumble of the electrical industry at the Board of Trade has not been warranted, in that the members when given their opportunity to direct have failed to take any advantage of that opportunity.

THE APOSTOLOFF AUTOMATIC TELEPHONE.

We were invited on Wednesday last to a Press view of the above-named telephone, or, rather, telephonic system. The invitation was for 3 p.m., but some Government officials who were inspecting the instruments kept Mr. Salomon Berditschewsky, the inventor, from seeing us till considerably after four. As a result the time at our disposal was too short to enable a full grasp of the automatic details to be obtained. The long wait was spent over cigars and in the pleasant company of a commercial official of the company. He had observed a nice distinction between the capabilities of technical experts and commercial men generally which was well worthy of public notice. Thus, after reading the evidence of Mr. W. H. Preece, C.B., on the telephone question at the recent Government enquiry, our entertainer was surprised to see the grasp Mr. Preece had of the subject seeing that he was a technical man. We were also told that the apparatus about to be viewed had been made specially large so that the technical men should understand it, but the commercial form would be either three-eighths the size, or else it was 3·8 times—he was not quite sure which, but anyway, it would be smaller.

The object of the invention devised by Mr. Berditschewsky (called Apostoloff) is to dispense with the use of the telephone operator and to make the subscriber control the cross-connections at the central exchange. In the telephone itself no change is proposed, but some small additional apparatus will be placed on the subscriber's instrument.

The troubles caused by the growth of telephonic exchanges as at present designed have been fully explained of late by Mr. Dane Sinclair in his historical paper before the Institution of Electrical Engineers, and are also referred to in the description of the Naglo-Hess-Raverot-West system now appearing in our columns. The multiplicity of contacts required increases rapidly as the number of subscribers goes up, and the limiting numbers with the present system are within sight. The main principle for reducing the number of contacts underlying this Apostoloff system is somewhat similar to that equipped by Messrs. Naglo and Co. at Berlin, but the principle is carried out farther. Before describing the apparatus we may well summarise the objects it is designed to fulfil.

The automatic system allows each subscriber to personally place himself in direct communication with any other subscriber in the same town without the aid of an exchange employé. It will also enable him to communicate with all the subscribers simultaneously. This last facility appears to us to be a decided objection. The advertising crank would certainly avail himself of the opportunity. The system can be easily extended to interurban work. Although certain cross-connections to other subscribers than the one wanted are at times made in the process of connection as soon as the subscriber wanted is rung up, all metallic connections with the exchange are cut off, and the direct through connections between the two leads and two returns only remain.

In this way there should be absolute secrecy of conversation as far as the exchange is concerned, but the system does not affect the induction trouble. The claim for a saving of time can only be substantiated on trial, but it is noted that while one subscriber is talking no one else can ring him up or interrupt. Also, the new subscriber who fails to ring him up gets no intimation beyond the failure to respond that the line is engaged. In what respect this is preferable to present systems we fail to see. We would call Mr. Berditschewsky's attention to the fact that the great cause of delay at present is not due to defective switching arrangements, but rather to busy firms being served by one telephone only. This telephone is often used for messages from the firm only for a considerable time, and other callers cannot get on. At present you do get the irritating message that Mr. So-and-so is engaged, but with the automatic system you would get no reply whatever, which would not be in any way more assuring.

Coming to the general principles of the mechanism devised to give the above result, we are sorry that time precludes us giving illustrations in this issue. The first point in the development of the automatic gear is to have a revolving contact in the exchange which will, step by step, put the subscriber on to every other subscriber. It will at once be seen that this would necessitate 10,000 contacts to each subscriber in a 10,000-number exchange were the elementary revolving contact to be used. The inventor gets over this difficulty as follows: In the condition of rest all the wires in the exchange are grouped into series of 100 each. There are, of course, two wires—one the lead and one the return—from each subscriber. Consider these arranged in a square block, with 100 wires each side. Then in the cube containing the lead wires one horizontal connection would join up all numbers from 1 to 100, another all wires from 101 to 200, etc. In the cube containing the returns the connecting wires would run vertically. Thus one wire would connect the numbers 1, 101, 201, 301 . . . 9,901; another wire would connect 2, 102, 202, 302 . . . 9,902. Now, with two revolving or sliding contacts, with 100 contact points, any one wire can be signalled out. Thus if the lead from the subscriber is made to the 'bus wire containing the numbers 801 to 900, and the return wire to the wire connecting all numbers ending in 2, the signal will be sent to the subscriber whose number is 802. The lead connections thus gives the first two significant figures in the subscriber's number, and the return the last two. The number of connections required at the exchange for each subscriber is therefore twice the square root of the number of subscribers. This principle is in the final form of the apparatus carried out a second time to still further reduce the number of wires and movements. In finding the subscriber's wires in this way two things are necessary—the first, a revolving contact at the exchange, and, secondly, a synchronously revolving indicator at the subscriber's end. This is effected by a step-by-step movement which cannot be described clearly without illustration. After a conversation the apparatus at both ends of the line return to zero, so that at the start absolute uniformity is ensured. The operation of calling consists first in pressing a button under a small aperture ruling the first two significant figures. Numbers appear at the window in rotation, and the caller presses the button again, when the correct number appears. He then adjusts the two terminal significant figures in a similar way at another window at the other side of the instrument. The number he requires to call will thus be readable on the instrument. The next action is to ring up the subscriber wanted. This effects two essential changes: the individual lines and returns are first

Digitized by Google

disconnected by relays from the group wires, and next are directly connected each to each. The two lines and returns are then wholly independent of the exchange. After this the rest of the operations are progressive, and not unlike those in an ordinary exchange. All the time the line wires are thus disconnected from the grouping wires no other subscriber can get on to them.

The general idea governing the system is thus a most excellent one, but the excellency of working depends on a large amount of automatic apparatus. We are assured by the inventor that £3. 3s. will cover the first cost for each subscriber. This may be so, but with automatic gear of the delicacy required the best of workmanship alone must be used, or else the cost of upkeep in skilled labour will be very large. In conclusion, the technical parts are well thought out, but it is a question as to whether the apparatus can be relied on commercially.

THE PRINCIPLES OF ALTERNATE-CURRENT WORKING.*

BY ALFRED HAY, B.Sc.(EDIN.), A.I.E.E.

(Continued from page 92.)

43. We have hitherto supposed that the alternating E.M.F. or current with which we have to deal is a simple sine function of the time. In many practical cases, the shape of the E.M.F. or current curve deviates more or less from the simple sine form. In some cases, such as that represented in Fig. 31, the deviation from the simple sine form is very slight; in others, again, such as that shown in Fig. 3, or the one in Fig. 33, the deviation is considerable. A knowledge of the shape of the E.M.F. wave of any given alternator is of considerable importance. The best shape of E.M.F. wave depends on the kind of work which the alternator has to do. Thus, a wave which would be very suitable for supplying transformers might prove totally unsuitable for supplying arc lamps. There is therefore no such thing as *the* best shape of E.M.F. wave for all purposes; whether a given shape is good or bad, depends on the nature of the supply.

The results which we have already established for simple sine waves may be extended to waves of any shape. For this purpose, however, we must be able to *analyse* any given wave into its *simple harmonic components.*

It may be shown that a periodic function is capable of being split up or analysed into a number of simple har-

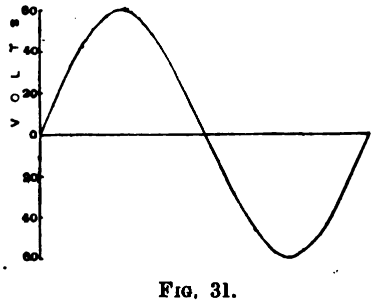

FIG. 31.

monic terms, whose periodicities are whole multiples of the periodicity of the given function. Thus, if n stand for the periodicity—*i.e.*, the number of periods per second—of the function, the periodicities of its simple harmonic components will be n, $2n$, $3n$, $4n$, and so on. If F denote the function, then

$$F = F_1 \sin(pt+\theta_1) + F_2 \sin(2pt+\theta_2) + F_3 \sin(3pt+\theta_3) + \dots$$

where p stands for $2\pi n$.

This expansion of a periodic function in a series of simple harmonic terms is due to Fourier, and is known as Fourier's expansion.

The number of terms in the expansion will depend on the amount by which the function deviates from the simple sine form. In many cases an infinite number of such simple harmonic terms would have to be taken to represent the function with *perfect accuracy.* But in practice the number of terms will depend on the degree of accuracy which it is desired to obtain And just as in calculating the square root of 2, say, we only carry the calculation to as many decimal places as will ensure the required degree of accuracy, so in using Fourier's expansion we take only the first few terms and neglect all the remaining terms. In order to ascertain the degree of accuracy corresponding to a given number of terms, we have merely to reconstruct the function from these terms, and compare the resultant curve with the graph of the given function.

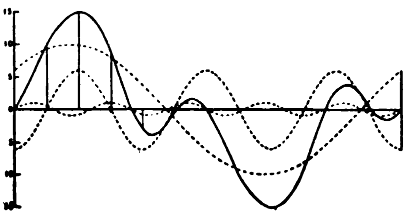

FIG. 32.

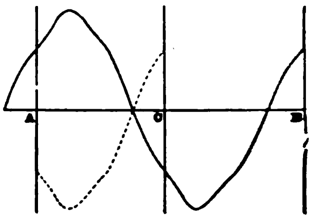

FIG. 33.

The expression given above for the harmonic expansion of a periodic function F may be thrown into a slightly different form. Since, by (8) of Art. 8,

$$F_1 \sin(pt+\theta_1) = F_1 \cos\theta_1 \sin pt + F_1 \sin\theta_1 \cos pt,$$

$$F_2 \sin(pt+\theta_2) = F_2 \cos\theta_2 \sin 2pt + F_2 \sin\theta_2 \cos 2pt, \text{ etc.,}$$

we may, putting $F_1 \cos\theta_1 = A_1$, $F_1 \sin\theta_1 = B_1$; $F_2 \cos\theta_2 = A_2$, $F_2 \sin\theta_2 = B_2$, write the expansion in the form

$$F = A_1 \sin pt + B_1 \cos pt + A_2 \sin 2pt + B_2 \cos 2pt + . \quad (25)$$

44. The E.M.F. curve of an alternator is a *symmetrical curve*—*i.e.*, the negative half-waves are an exact copy, with sign reversed, of the positive half-waves. This at once follows from the fact that the poles of an alternator (whether north-seeking or south-seeking) are all alike. A want of symmetry in the E.M.F. wave could only be produced by giving alternate poles a different shape.

In Fig. 32 is represented a periodic function, along with the simple harmonic terms into which it may be analysed (shown dotted). The sum of the ordinates of the three dotted curves gives us the full-line curve, which is the resultant function. In the present case, the function is represented by the sum of the three terms,

$$10 \sin(pt+\theta_1) + 6 \sin(3pt+\theta_2) + \sin 5pt,$$

where $\tan\theta_1 = \frac{3}{4}$ and $\theta_2 = -\frac{\pi}{2}$.

In Fig. 33 is represented the E.M.F. curve of a certain alternator. Let A and B be any two points the distance

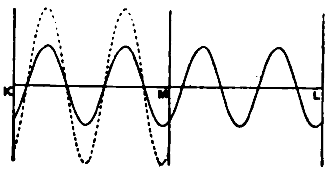

FIG. 34.

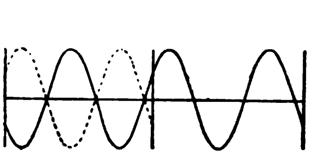

FIG. 35.

between which corresponds to a complete period. Divide A B into two half-periods, A C and C B. If now the portion of the curve included in the second half-period C B be superposed on that included in the first half-period A C, as shown by the dotted curve, it follows from the symmetry of the positive and negative half-periods that the resultant curve has every ordinate equal to zero. The two half-periods, therefore, into which any period of an E.M.F. curve is divided will, when superposed, cancel each other. From this there follows at once the important result that *an alternator E.M.F. curve contains harmonic components of an odd order only, and (so long as it is symmetrical) can contain no harmonic component of an even order.*

To prove this, let us suppose that a certain periodic function contains a harmonic component of an even order. Let this harmonic component be represented by the full-line curve shown in Fig. 34, and let K L correspond to a complete period of the given function. If we divide K L

* Based on a series of evening lectures delivered at the University College, Liverpool.

Digitized by Google

into two half-periods K M and M L and superpose them, then, since each half-period contains a whole number of periods (or an *even* number of half-periods) of the harmonic component under consideration, the resultant curve (shown dotted in Fig. 34) will be one whose ordinates are double those of the given harmonic component. Hence no *symmetrical* curve can contain a harmonic component of an even order, for, as we have seen above, the superposition of two half-periods of such a curve gives a resultant all whose ordinates are equal to nothing.

If, on the other hand, a periodic function contains a harmonic component of an *odd* order, as shown in Fig. 35, then the superposition of two half-periods causes that component to vanish, for each half-period of the given function now contains an *odd* number of half-periods of the harmonic component considered.

Having thus shown that an alternator E.M.F. curve contains harmonic components (or *harmonics*) of an odd order only, we need not further consider curves involving even harmonics. A function containing only odd harmonics may be written in the form

$$F = A_1 \sin pt + B_1 \cos pt + A_3 \sin 3pt$$
$$+ B_3 \cos 3pt + A_5 \sin 5pt + B_5 \cos 5pt + \text{etc.}$$

(To be continued.)

DESCRIPTION OF THE ALUMINA FACTORY AT LARNE HARBOUR.*

BY JAMES SUTHERLAND, MANAGER.

Sources of Aluminium.—Aluminium is one of the most abundant metals found in the earth. It is not met with in the metallic state, but its compounds with oxygen, fluorine, the alkalis, silicon, and the acids are so numerous and so widely diffused that it is almost impossible to obtain a portion of the earth's crust in which it will not be found. The compounds of aluminium with silicon and other bases are the most numerous. These in the form of felspar and mica, mixed with quartz, form granite. By the influence of air and water these compounds are decomposed, the alkali is replaced or carried away, and the residues form clays. Such precious stones as the ruby, sapphire, garnet, and cryolite also contain large quantities of the metal; the ruby and sapphire are almost pure oxide or alumina; and cryolite, a double fluoride of aluminium and sodium, is found in abundance, containing 13 per cent. of a luminium. But the clays present the largest source of the metal, and the mineral called bauxite is generally used for its production. Bauxite derives its name from the French town of Beaux, near which it was first discovered. Since that time large deposits have been found in County Antrim, where thousands of tons have been mined during the past 20 years, chiefly for the manufacture of sulphate of alumina and other salts of aluminium.

Analysis of Bauxite.—County Antrim bauxite contains: alumina, 56 per cent., corresponding with aluminium 29·9 per cent.; peroxide of iron, 3; silica, 12; titanic acid, 3; and water, 26 per cent. From this analysis it will be seen that, if the aluminium is to be obtained in a state of purity, the peroxide of iron, silica, and titanic acid must be separated out before the extraction of the metal from the alumina is attempted.

Alumina Factory. — The most convenient method for obtaining pure alumina from bauxite is that discovered by Dr. K. H. Bayer, which is used in the alumina factory at Larne Harbour. The factory is situated close to the terminus of the narrow or 3ft.-gauge line of the Belfast and Northern Counties Railway, whereby it is conveniently connected with the mines at Glenravel, 35 miles distant. The main building of the factory is 240ft. long and 80ft. broad, the loftiest portion being 30ft. high; it is built of brick, and covered with a slated roof on iron principals in two bays of 40ft. span each. Steam at 100lb. pressure per square inch is generated in two Lancashire boilers, 25ft. long and 8ft. diameter, fed by a direct double-acting duplex steam-pump, with pure water at 180deg. F. obtained from the evaporating apparatus. The necessary draught is obtained by a chimney 120ft. high. The driving power required is supplied by a horizontal non-condensing engine, with cylinder 14in. diameter and 20in. stroke, running at 140 revolutions per minute. The slide-valve has an expansion valve on the back, and the cut-off is regulated by a hand-wheel. The engine is capable of exerting 80 h.p. when working against a back pressure of 10lb. This amount of back pressure is due to the exhaust steam assisting in the heating of the evaporating apparatus. The power is transmitted to the main shaft, which runs at 200 revolutions per minute, by four 5½in. cotton ropes driving on the flywheel, which is grooved for the purpose.

Grinding and Calcining.—The trucks of bauxite as received from the mines are run directly into the grinding room. Here the ore is fed into a disintegrator, and ground to ½in. cubes, which fall down a shoot into the bottom boot of an elevator, whereby they are delivered into a riddle of ¼in. mesh. The ore which passes through the mesh descends a sheet-iron pipe into the calciner; while the tailings are returned to the disintegrator by gravitation, to be ground over again. The organic matters present in the ore require to be destroyed, and for this purpose calcination is resorted to. The calcination is important, because the presence of organic matters would retard, if not totally prevent, the subsequent separation of the alumina from the caustic soda in the decomposing cylinders. On the other hand, too great heat would cause the ore to become far less soluble in the solution of caustic soda.

Calciner.—The calciner consists of an iron tube 33ft. long and 3½ft. diameter, lined with firebrick, and mounted on rollers to permit of its revolving. It is inclined at an angle of 1 in 25, and is heated by a furnace at the lower end, from which the heat passes up through the tube and into a chimney at the higher end. As the tube revolves, the bauxite fed into the higher end travels downhill towards the lower end and meets the heat ascending from the furnace, which is regulated to suit the extent of calcination required. On leaving the tube the calcined ore falls upon a plate having a slot in it just large enough to allow the bauxite to pass. Through the slot it descends by a shoot into the cooling tube, which is 30ft long by 2½ft. diameter and also revolves, being inclined in the opposite way to the calciner tube. Here the ore is cooled by a current of air drawn through the tube by a fan connected with the opening. At the outfall of the cooling tube is placed a spiral conveyor, which discharges the ore into a second disintegrator, where it is ground sufficiently fine to pass through a 30 mesh sieve—that is, one with 30 holes per lineal inch, or 900 per square inch. Thence an elevator deposits it in a store having a hopper bottom, underneath which the small trucks can be run to be filled.

Kiers.—The alumina is extracted from the ground bauxite by treating it with a strong solution of caustic soda under pressure. A soluble compound of alumina and soda, called aluminate of soda, is thereby formed, while the peroxide of iron, silica, and titanic acid remain as insoluble compounds. This decomposition is effected in pressure kiers, which are constructed of mild-steel plates ⅝in. thick, and are 11ft. long by 5ft. diameter inside, and surrounded with a steam-jacket for heating. A horizontal 3in. shaft runs through the kier longitudinally, and is fitted with eight 16in. by 9in. paddles, which keep the contents in constant agitation. Stuffing-boxes are fitted at the ends of the kier, for the shaft to run in. Each kier is provided with a charging and a discharging opening, and a safety-valve; and the jacket with steam inlet, safety-valve, and water outlet, the latter being connected with a steam trap. The kiers have been tested to 200lb. per square inch, and are constructed to work at 100lb., although in practice about 80lb. is found to be sufficient for effecting the decomposition of the bauxite.

The necessary supply of caustic soda solution having been run in, usually of 1·45 specific gravity, the agitator is set going, and the bauxite previously weighed is admitted. This is done by a small elevator, which supplies the quantity automatically and regularly, thus ensuring thorough admixture. When the charge is all filled in, usually about three tons, the charging opening is closed, and steam is turned on into the jacket. The pressure is

* Paper read before the Institution of Mechanical Engineers.

Digitized by Google

slowly increased up to 70lb. or 80lb., which is maintained for two or three hours until the decomposition is complete. The discharge cock is then opened, and the mass is blown out by the pressure in the kiers up into the red-mud tanks, which are placed in the highest part of the building. Here the mass is diluted with washing water to a specific gravity of 1·23, and is then ready to be filtered in order to separate out the aluminate of soda solution from the impurities.

Filter Presses.—The filter presses used for this purpose each contain 50 chambers, giving cakes 30in. square and 1in. thick. The impurities being insoluble are retained in the press, while the liquid aluminate runs out into the filter tanks. When the press has become filled with red mud, the cakes before being removed from it are subjected to a systematic washing for extracting as much of the aluminate of soda as possible. The washing water is utilised for diluting the mass blown up from the kiers. Centrifugal pumps are employed for charging and washing the presses. Conveyors are placed beneath each filter press, which receive the cakes of red mud when the press is opened and deposit them on trucks placed outside the building. At present the red mud is useless, but experiments are being conducted which it is hoped will result in a profitable use being found for what would otherwise be a troublesome by-product.

Cellulose Filters.—The lyes from the filter presses, collected in the filter tank, are then subjected to another filtering process through cellulose consisting of papermakers' wood pulp. These filters are composed of lead-lined vats with sloping sides, 10ft. long by 6ft. broad and 3ft. deep, with a ledge round the inside 6in. from the bottom, on which is placed a sieve of ⅛in. mesh, supported on a frame. Two of these filters form a set, one placed above the other. About 50lb. of cellulose is boiled with water to a thin pulp, and is run upon the sieve in each filter; it soon settles down and is ready to receive the lyes, from which it retains all the finely-divided insoluble particles that have escaped from the filter presses; the result is a perfectly clean liquid composed of pure aluminate of soda. This final filtration is necessary if the alumina, and consequently the aluminium, is to be produced in a state of purity.

Decomposing Cylinders.—For the separation of the alumina from the soda the decomposition of the aluminate was formerly effected by blowing carbonic acid gas through the liquor, when the soda combined with the carbonic acid, forming carbonate of soda, and the alumina was set free in the form of hydrate of alumina. The carbonate of soda had afterwards to be retransformed by a chemical process into caustic soda before it could again be used for decomposing a fresh charge of bauxite. By the Bayer process the separation of the hydrate of alumina is brought about by the addition of excess of hydrate of alumina itself, and constant stirring in the decomposing cylinders, which are large circular tanks 13ft. diameter and 20ft. high, provided with agitators. In practice the liquid aluminate of soda from the cellulose filters is pumped up into large tanks of 4,800 gallons capacity, placed above the decomposers. The liquor can be measured and heated, if necessary, in the tanks. The decomposer, in which sufficient hydrate of alumina has been allowed to remain for beginning the decomposition, is filled, and the agitation started. In about 36 hours, 70 per cent. of the alumina in combination with the soda has separated out; and this is the extent to which the precipitation usually takes place. The agitator is then stopped, and the contents of the decomposing cylinder are allowed to settle. In a short time the hydrate of alumina settles to the bottom, and the clear liquor is run off the top by gravitation into the weak-liquor tanks.

Hydrate Filter Presses.—After as much as possible of the clear liquor has thus been decanted off, the hydrate of alumina is pumped out of the decomposing cylinder, sufficient being allowed to remain behind in the cylinder for beginning the decomposition of the next charge of liquor admitted. The hydrate of alumina pumped out is filtered through filter presses, and the weak liquor passing through the cloth is allowed to run into the weak-liquor tanks. The charging of the hydrate filter presses is done by a horizontal twin direct-acting steam-pump, with steam-cylinders 7in. diameter, rams 5in. diameter, and 12in. stroke. The pump is provided with an automatic arrangement for shutting off the steam when the presses are full: a ½in. pipe leads from the air-vessel, and when the pressure exceeds 80lb. it raises a weighted diaphragm, which closes a valve placed in the steam-pipe beneath the throttle-valve, and so cuts off the steam.

Washing and Drying.—When the filter presses are full, washing is commenced in order to remove the last traces of soda. The pump for this purpose is duplex direct double-acting, with 5¼in. steam-cylinders, 3½in. pump cylinders, and 5in. stroke. The washing is done systematically, as before, in five different stages, the last of which is with pure water. After washing, compressed air is forced through the cakes to remove as much water as possible. The air-compressor is horizontal, with steam-cylinder 8in. diameter, air-cylinder 6in. diameter, and stroke 14in. It has a suction capacity of 90 cubic feet per minute when running at 120 revolutions per minute and delivering at 80lb. pressure per square inch. The air-compressing cylinders are provided with water-jackets to keep them cool.

Calcining Furnace.—Conveyors are placed beneath the hydrate presses, which deposit the hydrate of alumina on the top of the calcining furnace, where the moisture and water of hydration are driven off. The furnace has a bed 20ft. long and 6ft. wide, and is fired with Dowson gas, for which the generator is placed in a small shed outside the main building, so that no dust may get mixed with the alumina. The products of combustion pass between the arch over the hearth and a drying tray placed above, on which the hydrate gets a preliminary drying before being admitted to the hearth. A low temperature is sufficient to drive off the moisture and the water in chemical combination, leaving the alumina perfectly anhydrous; but if formed in this way it takes up water again readily. To prevent it from doing so, the anhydrous alumina is heated to about 2,000deg. F., when it becomes crystalline, in which state it is not so liable to absorb moisture. It is important to have the alumina as dry as possible, for the presence of water means a corresponding loss of electricity during the subsequent reduction When the calcination is complete, the alumina is drawn into iron barrows and spread on a tiled floor to cool, after which it is ready to be packed in casks.

Evaporator.—The weak soda liquors from the decomposers and hydrate presses, having a specific gravity of only 1·2, are too dilute to dissolve the alumina out of the bauxite, and must, therefore, be concentrated by evaporation up to 1·45 specific gravity. The evaporator is of the triple-effect kind, and is capable of evaporating 33,000 gallons of water in 24 hours. It has independent feed, air, and circulating pumps, and the exhaust steam from these, as well as that from the main driving engine, assists in heating the evaporating pans. The circulating water is discharged into a small concrete tank or pond, whence it is pumped up by a 5in. centrifugal pump to the top of the cooling tower, which is 30ft. long, 20ft. wide, and 25ft. high, and is provided with four trays. During its descent into the pond the water is reduced 40deg. in temperature—namely, from 100deg. down to 60deg. F. The water evaporated from the weak soda liquors being pure, and having a temperature of 180deg. F., is used for washing the hydrate of alumina, and for boiler feeding, etc. It is stored in a lead-lined wooden tank of 6,000 gallons capacity, placed above the decomposers; the supply for the hydrate washing is filtered through a small cellulose filter placed beneath. All the drainage of the factory is collected in a concrete tank placed in the yard, and is pumped back, to be used for washing the red mud, dissolving soda, etc. Any soda, aluminate of soda, or water, which escapes by leakage or otherwise from any of the processes, is thus saved. The pump for this purpose is similar in size and make to the boiler feed-pump; it is placed in the boiler-house, and is arranged to feed the boilers in case of a breakdown of the feed-pump proper.

Electric Lighting.—A 15-unit Taunton dynamo is used for lighting the factory at night by means of 10 arc lamps of 2,000 c.p. each and 100 incandescent lamps of 16 c.p. and 32 c.p. The dynamo is driven by a Robey vertical steam-engine, from which the power is transmitted by

Digitized by Google

four cotton ropes of 1in. diameter. The dynamo and engine are self-oiling, and require very little attention.

Extensions.—Provision has been made for extensions, the buildings being capable of containing double the machinery already erected, and the beams and columns are already in position for receiving the additional apparatus which it is hoped an increasing demand will soon render necessary.

PLYMOUTH ELECTRIC LIGHTING.

The following is the report of Mr. John H. Rider, borough electrical engineer, to the chairman and members of the Electric Lighting Committee of the Corporation of Plymouth on the scheme for supplying electricity to the borough of Plymouth for lighting and power purposes:

At the outset I would express my entire agreement with the recommendations contained in the report of your sub-committee in December last—viz., (*a*) that the works should be on the shores of the Cattewater; (*b*) that they should be so designed that the waste heat from the destructor may be utilised if hereafter found desirable or feasible; (*c*) that electricity for traction purposes should be supplied from the same station; (*d*) that the ratepayers would derive a profit from the undertaking.

System Recommended.—After taking into consideration the position of the best available site for the works, the extent of the area proposed to be supplied at present, and the future extensions which must rapidly follow into the residential parts of the borough, I recommend that the alternating-current system be adopted for private lighting, with low pressure distributing mains fed from transformer sub-stations for the main streets, and with high-pressure distribution and separate transformers for the more scattered areas. Low-pressure distributing mains should be at first laid in the following streets viz., Old Town street, Ebrington-street, Ham street Treville street (part of), Bedford-street, Whimple - street, George - street, Cornwall - street, Market-avenue. Frankfort-street (part of), and Union-street. These mains would be fed from transformer sub stations built under the footpaths at approximately the following points—viz., (1) corner of Ebrington-street and Old Town-street; (2) St. Andrew's Cross; (3) corner of Bedford-street and George-street; (4) corner of Guildhall-square and Westwell-street; (5) Clock Tower; (6) corner of Union street and Bath-street. The sub-stations would be supplied by means of high-pressure feeder cables coming direct from the generating station. In addition to the above, I would propose to lay a high-pressure main along Lockyer-street to Citadel-road with a view of supplying the property in the immediate neighbourhood of those streets, to be laid in the same trench and at the same time as the arc lighting cables. I recommend that the distributing mains be of the triple-concentric type, on the three-wire system, protecting with lead sheathing and steel armouring, and laid direct in the ground. Service connections can be readily made on such cables when required, without the necessity of special pavement boxes or covers. These mains would not require enlarging to meet any ordinary future demand in the streets mentioned. The high-pressure feeding mains would be of the concentric type, protected with lead sheathing, and drawn into stoneware conduits. Services would not be taken from these cables, as they would go direct to the transformer sub stations to feed the low-pressure distributors. In laying the stoneware conduits spare "ways" would be provided, so that additional cables could be drawn in at any time without disturbing the surface of the footpaths.

Public Lighting.—For supplying the public arc lamps I recommend that either rectifiers or rotary transformers be used, whereby the alternating current is changed into a current always in one direction This will give the best results for street-lighting, and only one class of generating plant would be required at the works. I recommend that arc lamps should be fixed in the following streets and public places—viz.: Ham-street, 4; Ebrington-street, 4; Market-place, 1; Old Town-street, 6; Bedford-street, 6; George-street, 8; Millbay-road, 6; Union-street, 15; Lockyer-street, 3; Guildhall-square, 2; Westwell-street, 1; Catherine-street, 1; Hoe-promenade, 10; Hoe-slopes, 4; Hoe-park, 1; Osborne-place, 2; total, 74 arc lamps. They would be generally placed on opposite sides of the road, and at 11 p.m. every other lamp would be extinguished. Each arc lamp would give approximately 1,500 c.p. at an angle of about 45deg. from the post. This would be a total illumination of 111,000 c p. The gas lamps displaced in the above streets amount to 123, of sizes varying from 15 c.p. to 100 c p. The total light given by them is about 4,730 c.p. I propose that each arc lamp should be charged for at the rate of £16 per annum, which sum would include all charges for current, cleaning, trimming, repairs, etc. The total cost for the arc lighting would therefore amount to £1,184 per year, with a candle-power of 111 000. The gas lamps displaced by the above are costing £475 per year, with a candle-power of 4,730. While the cost of the arc lighting would therefore be 2½ times the cost of the gas lighting, yet the candle-power obtained would be over 23 times that of gas, or in other words, the light would be about nine times as great for the same money. The comparison would be still more favourable to the electric light if the reduced lighting after 11 p m. were taken into account. While the 123 gas lamps reduce from 4,730 c.p. to 1,845 c.p., the arc lamps reduce from 111,000 c.p. to 55,000 c.p. The arc-lamp mains would consist of twin conductors protected with lead sheathing and steel armouring, and laid direct in the ground. The lamps would be arranged on two or more circuits, and would be carried on cast-iron pillars at a height of about 22ft from the ground. The distance apart of the lamps may be seen from the map. It varies from 40 to 90 yards, the average being about 50 yards.

Electric Traction.—In those streets in which electric traction may be afterwards adopted, the arc lamp-posts could be most conveniently arranged to carry a trolley wire from short bracket arms, thus largely reducing the number of actual posts required. The new tramway route from the Market-place to Prince Rock, *viâ* Ebrington-street, Ham-street, Beaumont-road, Tothill-road, and Embankment-road is an exceedingly favourable one to be first equipped for electric traction. It has a total length of 23,000 yards, and with four running cars a five minutes' service could be maintained. I recommend that the electric lighting department should lay the necessary underground cables, and that current should be sold to the tramway department at an inclusive price of 3½d per unit. The cost of the motorcars, and of the overhead trolley wire, with the posts, or other line equipment, would be borne by the tramway department When posts were used both for the trolley wire and for arc lamps, the cost should be divided between the two departments. I consider that the whole of this line would be best served by the overhead trolley wire, carried from short brackets, and that a swivel trolley arm should be used on the cars. Thus, instead of carrying the trolley wire right out over the centre of the track, necessitating long and heavy bracket arms, the trolley arm on the car would lean over to meet the trolley wire, which would be carried on brackets with comparatively short arms. I consider that with due care in the selection of the design of the posts and bracket arms, the overhead line can be put up so as to offend none, while for commercial success the system has no rival. The overhead system is almost universal in the United States. It is used on the Continent in many of the most important cities—such as Rome, Milan Havre, Brussels Zurich, Geneva, Rouen, Hanover, and Hamburg. It has been adopted at Bristol, Walsall, Coventry, Hartlepool, Dublin, Leeds, and Guernsey in the British Islands. The Glasgow, Birmingham, and Leeds Corporations have just sanctioned its use over their sytems. The Bolton Corporation has recently adopted a report recommending its use. The report of the deputation from the Glasgow Corporation contains the following: "The one great and practically the only serious obj ction urged against the overhead wires is the objection to their appearance. . . . We started our investigations more or less in sympathy with this objection, but we are bound to say that what we have now seen has quite removed from our minds objection to the overhead wires. Where the system is carried out in the most approved manner, we found that the wires give only the very slightest offence to the eye, and that a few hours' familiarity removed the objection entirely." The Lord Mayor of Belfast, in his report, says: "Having regard, therefore, to the fact that all practical objections to the overhead system have been surmounted, and that any exceptions thereto from an æsthetical point of view have been reduced to an almost infinitesimal quantity in the best examples of the overhead system, the deputation feel perfectly confident that they are doing the right thing in recommending that system." Trailer cars could be attached to the motorcar on occasions of heavy traffic, and the working expenses of the line should not exceed 6d. per car mile, with current supplied at 3½d. per unit. The advantages of an electric tramway load to a lighting station are almost too great to express. By the very nature of things, the lighting plant is practically idle during 18 out of the 24 hours. But by serving a tramway system, current can be sold during all the hours of daylight as well as of darkness, and thus the output for a given amount of machinery is enormously increased. It will, of course, be understood that the electric lighting scheme proposed in this report is independent of the exact form of electric traction adopted, and can, if thought expedient, be carried out, leaving open for the further consideration of the Tramways Committee and the Council the question as to the actual system to be used. I know of no town more advantageously situated than Plymouth for making its electricity works a success, even from the beginning, and when the whole of the tramway system is supplied from the same works, the cost of production will have been brought down to an exceedingly low figure

Generating Station.—I consider that the most suitable position for the electricity works is on the site of the Prince Rock cottages. The new Prince Rock approach road leads directly to it, and will form the most direct route for the mains into the town. The station buildings can be placed parallel with the railway, which will lie between them and the Cattewater. A wharf for unloading coal would have to be provided, with a line crossing the existing railway, running direct into the works. At the back of the station buildings is an excellent spot for the destructor work, and arrangements could be readily made at any time to utilise any surplus heat or steam from them. There would be no difficulty in procuring abundance of condensing water at all states of the tide. I recommend that the station buildings should contain at first the following plant—viz., three Lancashire boilers, with mechanical stokers and coal-conveying plant; two direct-coupled steam alternators, each for 200 kilowatts; two direct-coupled steam alternators and dynamos, each for 100 kilowatts; and the necessary switchboards, pumps, condensers and other apparatus. The 100 kilowatt sets would be special combinations which could be used either for (*a*) tramway work alone, (*b*) lighting alone, (*c*) tramway and lighting at the same time, (*d*) a motor-alternator for lighting, by unclutching the engine and driving from the accumulators, or (*e*) a motor-generator for tramway work, by unclutching the engine and driving from one of the other alternators. The

Digitized by Google

steam-engines to be of the vertical compound condensing pattern, the smaller ones running at a fairly high speed and the larger ones at a moderate speed. The engines to be of the enclosed type, with lubrication to all bearings under pressure. Provision to be made for erecting an additional boiler and a 300-kilowatt direct-coupled set, without alteration to the buildings, but the buildings to be so arranged that they may be easily extended at any time to meet further demands. I propose to work all auxiliary machinery, such as pumps, mechanical stokers, coal conveyors, etc., by means of electric motors, as being much more economical than by a number of small separate steam-engines. For use in connection with the traction plant, I propose to erect a battery of accumulators at the works. These would be charged during the hours of light load—from midnight to 6 a m —would help to meet the sudden demands for current on starting the tramcars; and would take the whole of the car load if required during a few hours each day, besides having several other incidental advantages and uses. The above plant would give an effective output of 400 kilowatts, leaving 200 kilowatts as spare. This would enable the equivalent of between 7,000 and 8,000 8-c.p. lamps to be supplied at one time (equal to about 12,000 8-c.p. lamps connected), besides the arc lighting and the one section of the tramways.

Capital Outlay.—I estimate the capital outlay necessary to be as follows—viz.:

Site	£400
Buildings, foundations, chimney, siding, and wharf	7,000
Engines, alternators, and dynamos	11,250
Boilers, economisers, piping, condensers, pumps, etc.	4,850
Accumulators, switchboards, testing, instruments, etc.	2,400
Travelling crane, oil tanks, filters, station lighting, and general fittings	1,050
High and low pressure mains, conduits, arc lamp mains and traction mains	9,300
Transformers and sub-stations	1,000
Arc lamps and pillars	1,850
Special apparatus for arc lamps with switch gear	1,300
House meters, etc.	1,000
Engineering charges and contingencies	4,600
Total	£46,000

Or about £76. 12s. per kilowatt installed. I therefore recommend that application be made to the Local Government Board for permission to borrow £46 000 for electricity purposes.

Income.—The annual income will be derived from three sources: (1) the tramways, (2) the public lighting, and (3) the private lighting. The car service on the Prince Rock line may be taken as starting from 7 a.m. to 8 a.m., or on the average at 7 30 a m. and ceasing from 10 20 p.m. to 11.20 p m., or on the average at 10.50 p.m. This gives about 15 hours per day per car. As each car will do six single journeys per hour of 2,300 yards, and four cars will be running, we have 6 × 4 × 2,300 = 55,200 yards, or 31¼ car miles per hour. Taking 313 working days per year, we get 15 hours × 31¼ car miles × 313 days = 146,953 car miles per year. Experience has shown that an electric car will take on the average one B.T. unit per mile to drive it. So that we may reckon on an output of about 147,000 units per year for this one section of the tramways The public lighting, consisting of 74 arc lamps at £16 per annum, will bring in a revenue of £1,184. The lamps will take approximately 83,500 units per annum, and the charge therefore comes out at about 3·43d. per unit. It is difficult to estimate the extent of the private lighting for the first year, but judging by the experience of other towns, it will be safe to reckon on a connection of at least 5,000 8-c.p. lamps at the end of the first winter, and of at least 10,000 8-c.p. lamps at the end of the first complete year. Assuming a connection of only 7,500 lamps, this should bring in a revenue of about £3,000. The annual income may be therefore taken as approximately:

Tramways, 147,000 units at 3½d.	£2,143
Public lighting, 74 lamps at £16	1,184
Private lighting	3,000
Total income	£6,327

This income would rapidly increase with an increasing private connection, and also as other sections of the tramways were converted to electric traction, without a proportionate outlay either on capital or running expenses.

Expenditure.—The annual running charges may be estimated as follows—viz.:

Coal, 2,000 tons at 12s.	£1,200
Waste, water, oil, and sundries	100
Workmen's wages at generating station	900
Lamp trimmers, carbons, and repairs to public lamps	450
Salaries—engineering department	760
Office expenses	75
Repairs and maintenance	180
Rates, taxes, and insurance	150
Total working costs	£3,815

This leaves a profit of (£6,327. less £3,815) £2,512 to pay the interest and sinking fund on £46,000, which will amount to £2,497. It will thus be seen that with a moderate private lamp connection, not only will all working costs be met, but the whole of the annual capital charges will be extinguished. At an early date it should therefore be possible to reduce the charges for current all round—to the tramways, and the public lamps, as well as to the private consumer.

Method of Charging.—Instead of charging the private consumer at an uniform price per unit, with discounts based upon the total quantity used, I strongly advise that the Brighton method of charging should be adopted, which gives a great advantage to those consumers who use their light for long hours. The greater part of the works' cost are incurred through being ready to supply, and after those charges have been met, the actual cost of producing the electricity is very small. It is therefore to the advantage of the department to encourage long-hour customers, and I recommend that the charges should at first be: 8d. per unit for all current supplied to lamps which burn one hour or less per day; 3d. per unit for all current supplied over and above one hour per day. For example, a customer who burned his maximum number of lamps for two hours per day would be charged 8d. per unit for the first hour and 3d. for the second, or an average of 5½d. per unit for the two hours. By the use of an instrument called a "demand indicator," placed in connection with the meter of each consumer, and upon his premises, the proper charges are most readily ascertained. As the works would be in operation throughout the day for working the tramways, I recommend that a continuous 24 hours' service be given from the commencement of the undertaking.

If this scheme meet with your approval I should be instructed to prepare the necessary plans and specifications for the various sections of the work without delay, and to invite tenders for the same, in order that no time may be lost in getting to work.

COMPANIES' MEETINGS AND REPORTS.

CENTRAL LONDON RAILWAY COMPANY.

The ordinary half-yearly general meeting of this Company was held on Tuesday at the Cannon-street Hotel, E.C., Mr. Henry Tennant (the chairman of the Company) presiding.

The **Chairman**, in moving the adoption of the report and accounts, stated that the directors had at that time 904 shareholders on the list, which was an increase on the number they had in June. At that stage of the history of the Central London Railway there was not much to say. It was, however, a great satisfaction to be able to point to the fact that a great beginning in the works of the railway had been made. Possession had been obtained for sites for the stations at Shepherd's Bush, Holland-park, Notting Hill-gate, Westbourne, Marble Arch, Oxford-circus, Tottenham Court-road, British Museum, and Chancery-lane. It had also been considered expedient to enlarge the proposed station in Newgate street, near the Post Office, and there would consequently be some delay in acquiring the additional property in connection therewith. It had been thought wise to secure the property as soon as possible, as it would be much more costly to enlarge the station in years to come At Shepherd's Bush, Chancery-lane, Westbourne, Marble Arch, and the British Museum the work of sinking the shaft had been commenced. With regard to the station at the Marble Arch, a beginning had been made a few days ago. The station which was to be made in the space opposite the Royal Exchange in the centre of the City, had also been commenced, and a start had been made with the subways near Broad-street Station The Great Eastern Railway had approved of the plans by the engineers for the station at Liverpool-street, and it was hoped that an agreement satisfactory to all parties would soon be arrived at. The requisite property for the Newgate Station had not been acquired, although arrangements were in progress. The station site between the Marble Arch and Oxford-circus had not been arranged. It was satisfactory to know that six miles out of a total of 6¼ of the railway had been let. The engineers had reported that great progress had been made all along the line in the ironwork, and for the preparation of the shield. The outlay for the half-year had amounted to £273,812. 14s. 9d., which, added to the amount previously expended, would make a total of £442 098. 0s. 11d. In the general balance-sheet the Chairman said the shareholders might have observed an item of £70,000 put down as "Mansion House Works Deposit Account." He explained that the City authorities were anxious that the work of the station in front of the Exchange and near the Bank should be proceeded with as quickly as possible when once begun. To assure the authorities on that point the directors were required to lay down that deposit, which had been securely invested in Consols, and thus all the difficulties and objections in connection with their taking possession of the site had been removed. The payments made had been so large that it had been found necessary to make a call of £2 per share, payable on September 1 next. Some of the shareholders had desired to pay the calls in full, and since the issue of the report in which the notice was given a large number of applications had been received, though they did not cover any huge amount of money. Most satisfactory progress had been made in all the preliminaries and in the actual work as far as circumstances would permit. The Electric Traction Company had shown a disposition, he was glad to say, to press on with the work as fast as possible.

Lord Colville of Culross seconded the resolution for the report and accounts, and it was carried unanimously.

The meeting was made special to consider resolutions relating to splitting the shares as follows: "(1) That every share in the Company's capital upon which not less than 60 per cent. has been, or shall at any time have been, paid up, and with respect to which the directors shall at any time have received a notice in writing signed by the holder or holders thereof signifying his, her, or their desire that such share should be divided, shall upon receipt

Digitized by Google

of such notice as aforesaid be divided into two half-shares, of which one shall be called 'preferred half-share' and the other shall be called 'deferred half share.' (2) That upon every such division 50 per cent. upon the entire share shall be carried to the credit of the deferred half-share (being the whole amount payable thereon), and the residue to the credit of the preferred half-share. (3) That the interest which would, under the powers and provisions in that behalf in the Company's special Acts, from time to time or at any time be paid or payable on any divided share if the same had continued an entire share, shall be applied in payment of interest on the two half-shares in proportion to the amounts credited as paid up on such half-shares respectively. (4) That the dividend which would from time to time be payable on any divided share, if the same had continued an entire share, shall be applied in payment of dividends on the two half-shares in manner following—that is to say, first, in payment of a dividend at the rate of £4 per cent. per annum on the amount for the time being paid up on the preferred half-share, and the remainder, if any, in payment of dividend on the deferred half-share, but so that no greater amount of dividend shall be paid on the two half shares than would from time to time have been payable on the entire share if the same had not been divided. (5) That the directors be, and are hereby, authorised to do all acts and things necessary for giving effect to the foregoing resolutions."

The **Chairman**, in reference to this, said that these resolutions, if passed, could be acted upon on the authority of their Railway Act of 1891. In the schemes submitted for the division of stock some shareholders had thought that the directors wanted to increase the nominal amount of capital. In that proposal it was not intended to increase the nominal capital at all. What they intended was, he thought, explicitly explained in the resolutions. The option of dividing the shares was left entirely in the hands of the shareholders.

The resolutions were seconded by **Lord Rathmore**, and carried unanimously.

LIVERPOOL OVERHEAD RAILWAY COMPANY.

The ordinary half-yearly general meeting of this Company was held at Liverpool on Tuesday, Sir William B. Forwood (chairman) presiding.

The **Chairman**, in moving the adoption of the reports and accounts, said he might fairly claim them to be satisfactory. They showed that the traffic on the overhead railway was making steady progress, that the line was being more largely used by the commercial community of the port, and that it was extensively patronised by visitors and sightseers. During the past year they had earned £31,286, and had expended £19,694, leaving a profit of £11,592. Out of this sum they had paid £2,500 as interest upon their debenture bonds, leaving a balance of £9,092, which added to the balance of £2,074 brought forward, gave them a total sum of £11,166 to deal with. The directors proposed to pay 5 per cent. preference dividends, which would absorb £2,700, and a dividend of 2¾ per cent. on the ordinary shares, which would take £5,568. They would thus be enabled to carry forward £2,897. At the same period last year they paid a dividend of 2¼ per cent and carried forward a balance of £1,302. Some directors might think the present balance carried forward rather too large, but if they were able, as they now hoped, to pay a dividend of 3 per cent. next year, they would have to make an additional contribution to the tramway company, and they thought it judicious to make provision for that extra expenditure. Their receipts had increased by £3,154 as compared with the corresponding half of last year, and their expenses in the same period had increased to the extent of £1 141. Of that sum £400 represented rates, an item over which they had no control and which, he regretted to say, seemed to be increasing year by year. The extra revenue of £3,154 had thus been earned with an additional expenditure upon the lines of £600. The average receipts per passenger during the half-year had been 1·96d., against 1·92d. in the corresponding half-year of 1895 whilst their revenue per train mile had been 15·10d., against 14 38d. He regarded these items as exceedingly gratifying. They had incurred an additional expenditure of £485 upon repairs to structure and opening bridges, and of £240 upon stations, but this represented almost entirely the cost of extra painting. They had now got the structure in a splendid state of preservation, and they trusted that in a year or two they would be able to relax their expenditure somewhat upon this item. They were using their electric power for the purposes of painting. The outside of the structure was being painted by means of a machine which put on the paint with a spray, and the machine was worked from their electric conductor on the railway. In this way the cost of labour was reduced nearly one-half—in other words, from 20s. to 11s. 6d. They were also putting £175 more towards their renewal fund, which now amounted to the very satisfactory sum of £5,700. The cost of their locomotive power per train mile had been 3·40d. against 3·49d. last year. He regretted to say that the progress of the works at the south end had been somewhat delayed. They had had a difficult piece of construction in connection with the Cheshire Lines Railway. They crossed the Cheshire lines in tunnel, and the necessary works to make it an efficient crossing had been more difficult than was at first contemplated. It had also been found necessary to construct their bridge with one span instead of two, and this had led to further delay, but he was glad to say that the difficulties were being rapidly overcome, and there was no doubt that the additional works would be open for traffic on November 1.

Mr. Richard Hobson seconded the motion.

Mr. Okell enquired how long the directors proposed to continue their payment of £1,000 per annum to the tramway company.

The **Chairman** replied that the agreement with the tramway company was on a sort of sliding scale. They paid the company £1,000, but they also made additional payments according to the amount of their dividends.

Mr. S. Stitt pressed for further information on the matter, enquiring in what way the overhead railway company benefited by the arrangement.

The **Chairman** stated that during the first two or three years of their existence they encountered fierce opposition from the tramway company, who ran a line of omnibuses from one end of the dock lines to the other every five minutes, and carried passengers at a penny apiece. They suffered considerable injury in this way, and ultimately arrangements were made for the discontinuance of this opposition on an annual payment of £1,000, with an understanding as to additional payments as the dividends increased. The tramway company undertook in addition to run certain lines of omnibuses as feeders to the overhead lines, and to place themselves entirely at the Company's disposal in the event of their ever being threatened with opposition. The directors had under contemplation the desirability of approaching the tramway company to obtain some modification of the terms. They could bring the agreement to a close on a six months' notice given by either side, but they did not think that judicious.

The motion was then approved, and the dividend of 5 per cent. on the preference and 2¾ per cent. on the ordinary shares was passed.

MANCHESTER EDISWAN COMPANY.

The annual meeting of the Manchester Edison Swan Company, Limited, was held last week at the rooms of the Manchester Society of Chartered Accountants, 65, King-street.

In the directors' report, submitted by the secretary (Mr. J. E Sharples), it was stated that the net profit, including last year's balance, amounted to £2,041. 18s. 1d. Out of this it was proposed to pay a dividend at the rate of 5 per cent. per annum, which will absorb £1 500, and to carry forward the balance, amounting to £541. 18s. 1d.

Mr. V. K. Armitage (chairman), in moving the adoption of the report, referred to the competition, not only keen but unscrupulous, to which the Company was subjected by its rivals in its efforts to obtain business.

Mr. W. P. James Fawcus, in seconding the motion, explained that the electric installation at Altrincham, on which there was last year a loss of £400, had now begun to pay. The number of customers was steadily increasing. The Altrincham Electric Supply, Limited, had also got a provisional order for supplying the electric light to Ashton-on-Mersey, and in all probability a beginning would be made with the laying of the mains within the next month or two. At a comparatively small outlay they would thus be enabled to tap another populous district and to increase the profits of the company.

The report was unanimously adopted, and the dividend recommended by the directors was passed. Thanks were accorded to the directors for their services, and a sum of £250 was voted to them.

CHILI TELEPHONE COMPANY, LIMITED.

The ordinary general meeting of this Company was held last Friday at Winchester House, E.C., Mr. George Keith, chairman, presiding.

The **Chairman**, in moving the adoption of the report, said the business of the Company had made considerable progress during the past year. The gross revenue had been 619,826dol., an increase of over 11 per cent. on the previous year, and the number of subscribers had increased by 237. On the other hand, the general expenses showed a marked reduction. The net profit for the year was £8 551, as against £6,013 in the previous year, an increase of £2,538. It was proposed to pay a dividend of 4 per cent. per annum. During the year the Company's property had been considerably improved and extended, a number of rural lines having been added, and, with the exception of some of the older lines, the property throughout was in good condition. The settlement arrived at between Chili and the Argentina had done much to restore confidence, and the course of events seemed tending towards a revival of business, from which the Company would necessarily derive benefit.

The report was adopted.

ALUMINIUM COMPANY, LIMITED.

The ninth ordinary general meeting of this Company was held on Friday last at the Cannon-street Hotel, E.C., Sir Henry E. Roscoe presiding.

The **Chairman**, in moving the adoption of the report, said although Mr. Gerald Balfour, M.P., had felt compelled to resign the chairmanship of the Board, he had consented to continue as a director. The ordinary business at Oldbury had resulted satisfactorily, and the profits had exceeded those of the preceding year, but it was to the sales of patents, for which the Company was indebted to the inventive genius of Mr. H. Y. Castner, that they owed £33,523 out of their total realised profits of £50,681. But beyond this they had shares of the nominal value of £119,000, which he thought was no more than their actual market value. Their net profit for the year, including amount brought forward, was £40,079. After careful consideration, the directors decided upon recommending a dividend of 15 per cent., writing £10,000 off works and a like sum off patents,

Digitized by Google

carrying forward £11,079. This of itself secured a future dividend and put the Company in a secure position. Their £12,000 10 per cent. B debentures had been paid off, and their £100,000 6 per cent. debentures would be liquidated in October, partly by the issue of £90,000 4½ per cent. first mortgage debenture stock, thus reducing the debenture debt by £21,800 and saving £3,363 a year in interest. Their revenue would further be augmented in future by dividends on their holding in the Castner-Kellner Alkali Company, besides which they would receive a fixed royalty of £4,000 a year from the Mathieson Alkali Company, which was erecting large works at Niagara Falls for the manufacture of caustic soda. They also held a large interest in the Niagara Electro-Chemical Company, which should yield a good profit, as the works erected by that company at Niagara Falls were now practically finished, and would be started this month. The Aluminium Company held 27 per cent. of the capital of the American company, which for various reasons was nominally only fixed at £20,000, so that the figure £5,400 in the balance sheet did not represent anything like the value of their proportion of that company's property—*i.e.*, that the shares represented by £5,400 were at the present time worth more than that amount. It had lately come to the knowledge of the Board that the Company's sodium patents were being infringed in Germany, and proceedings had been instituted to stop the manufacture. There was every reason to believe that those proceedings would succeed, in which case the Oldbury business would be much increased, and consequently profits also. Patent lawsuits in Germany were, fortunately, not so expensive as in this country. Negotiations referred to last year respecting British and Continental patents corresponding to those sold to the Niagara Electro-Chemical Company were likely soon to be brought to a satisfactory issue.

Sir Andrew Clarke seconded the resolution.

The **Chairman**, in reply to questions by Mr. Dyer, said the B shares were held chiefly by the directors and their friends The suggestion that a settlement and a quotation on the Stock Exchange should be applied for was being attended to by the directors.

The motion was then agreed to unanimously.

A dividend of 15 per cent. was then declared, payable on the 15th inst , and

On the motion of **Sir Andrew Clarke**, seconded by **Mr. Castner**, the retiring directors (Mr. John S. Parkin and Sir Henry E. Roscoe) were re-elected.

IMPERIAL TRAMWAYS COMPANY, LIMITED.

The ordinary general meeting of this Company was held at Bristol last Saturday, Mr. Geo. White presiding.

The **Chairman**, in moving the adoption of the report, an abstract of which has already been given in these columns, said the prospects of the Middlesbrough tramways' undertaking were improving, and at Reading there were evidences of development, the profit there being sufficient to pay 6¾ per cent. upon the Reading share capital. Extra expenditure had. however, been incurred in order to meet omnibus opposition. He then referred to the history of the Dublin Southern Tramways. The question of the loss of the parliamentary Bill need not occupy attention now. Having opened the electric tramway and worked it for a few weeks they were able to demonstrate that their opinion as to the value of the property was a correct one, and the British Thomson-Houston Company, who owned the preference and debenture capital, agreed to purchase the whole of the ordinary share capital which the Imperial Company owned for £130,000 subject to the payment by the Imperial Company of certain liabilities of the Dublin Southern Tramways Company. The Thomson-Houston, on their part, had been able to sell practically the whole concern to the Dublin United at a sufficient sum to cover their outlay and the purchase price paid to the Imperial—a very satisfactory deal, he thought, all round. It was true the Dublin United had had opportunities of purchasing the Southern lines, and the late chairman told him he offered the whole of their interest in the Southern to the United for £20,000. All along the Imperial Company had kept the purpose in view of showing the public and experts in Dublin that the Southern undertaking was all they claimed for it, and in the end they had every reason to be satisfied. Although the United had paid what some people would consider a high price, they had acquired valuable property without paying too dearly for it, seeing the amount of anxious work and ability put into the concern to bring it to the present state by the managing director, Mr. Robinson. The Imperial Company's accounts showed they had received £30,000 on account of the purchase price, and the balance was payable at the end of the present half-year. Between now and February next they hoped to suggest some mode of dealing with the money so received, especially as their position would be somewhat affected by whether or not they disposed of one of their undertakings about which they were now in negotiation. However, it was satisfactory to know that instead of the Dublin ordinary shares they would possess golden sovereigns to the extent of the total share capital of the Imperial Company, and it would be time enough when they were banked to settle the disposition of the money. Any shareholder anxious to anticipate that end could readily sell out at par, £6, rather a different price from three or four years ago, when shares were unsaleable at 15s. The gross revenue, omitting all credit on Dublin account, amounted to a sum sufficient to pay debenture interest and preference dividend at the rate of 6 per cent. and dividend on ordinaries at 2½ per cent., carrying forward a small amount to the new account.

The report was adopted.

CONTRACTS FOR ELECTRICAL SUPPLIES

CONTRACTS OPEN.

Oldham.—The Corporation want tenders by 18th inst. for an electric feed-pump. Particulars from Mr. Andrew, Gas and Water Offices, Oldham.

Nava del Rey (Spain).—The Municipality are open to receive tenders up to August 28 for the electric lighting of Nava del Rey for a period of 20 years.

Bucharest.—Tenders are wanted by August 19 for the electric lighting of the Boulevard Coltea. Application should be made to the Mairie, at Bucharest.

Dortmund (Germany).—The Municipal Authorities of Dortmund want tenders by September 1 for engines, boilers, and dynamos for the electric lighting of the town.

Cassel (Germany).—Tenders are wanted by the Slaughter-house Committee for an electric lighting installation of 80 incandescent and 14 arc lamps. The date is August 15.

Vich (Spain).—The contract will be allotted by the municipal authorities of Vich on August 17 for the electric lighting of the town for 10 years from June, 1897. The annual payment proposed is about £800.

Spa (Belgium) —The Burgomaster and Echevins of Spa invite propositions for undertaking the public lighting, either electrically or by acetylene. The date fixed is September 15. No further information is given in the official advertisement.

Copenhagen.—Tenders are wanted for the supply of 20,000 incandescent electric lamps. Application should be made to Directeuren for Kjöbenhavens Belysningsväsen, Gothersgade, 30, Copenhagen, and tenders must be in by August 22

The Hague.—Tenders are wanted by August 24 for the supply to the Dutch Government of iron telegraph posts, galvanised iron wire (telegraphic insulator pins, etc. Application should be made to the Dutch Colonial Ministry at the Hague.

St. Pancras.—Tenders are wanted for the supply and erection of 80 arc lamp columns about 19ft. high, for the St. Pancras Vestry. Particulars are obtainable at the Vestry's Electric Department Offices, 57, Pratt-street, Camden Town, N.W., and tenders must be in by August 24.

Villefranche-Lauragais (France).—The Municipality of Villefranche-Lauragais (Haute-Garonne) have invited competitive plans for a public water supply and electric lighting. Prizes of 1,000fr., 500fr., and 200fr. are offered, under the usual conditions, and schemes must be sent to the Mairie by October 10.

Dundee.—The Gas Commissioners invite tenders for the supply of indiarubber-covered cables for electric lighting in the Overgate, Wellgate, and Whitehall-street districts of the city. Particulars as to quantities, etc., can be had from the Electrical Engineer, Dudhope-crescent-road, Dundee. Tenders to the Clerk of the Commissioners, City Chambers, Dundee, by 19th inst.

Simla (India).—The Municipality is inviting tenders for lighting by electric light for a term of years the principal thoroughfares and buildings belonging to the Municipality. Tenders must be submitted by September 1 next. Should any proposal be accepted, the Municipality will afford the successful tenderer all facilities to extend the system of lighting to private houses.

Cologne.—Tenders are required by the Municipal Authorities for the construction and working of electric tramways in the city of Cologne to an aggregate length of 20·3 kilometres (12½ miles). Specifications, plans, and particulars are obtainable for 10 marks (10s.) from der Registrateur B, des Oberbürgermeisteramt, Köln, Germany, and tenders must be in by November 6.

Madras.—Tenders are invited for the lighting by electricity of Government House, Madras, including the banqueting-hall and aide-de-camps' bungalow, and also for the lighting of Government House, Guindy, including the military secretary's bungalow. For particulars application must be made to the consulting architect to the Government, Chepank, Madras. Tenders will be opened on November 11, 1896.

Radcliffe.—The District Council invite tenders for the supply and erection of a gas-engine and dynamo and the fitting up and lighting of the Technical School by electricity. A copy of the plans, sections, and specifications may be obtained on payment of 10s. 6d., and forms of tender obtained from the Surveyor, Council Offices, Radcliffe. Sealed and endorsed tenders to be sent to Mr. J. Sharples, clerk by 17th inst.

Voghera (Italy).—In view of the expiration of their contract with the local gas company in 1898, the municipal authorities of Voghera are desirous of receiving during the present year propositions for the lighting of the town either by the electric light or a mixed system of gas and electricity. The population is 16,000. Application should be made to L'Administrazione Comunale, Voghera, who will give all particulars necessary.

Mayaguez (Puerto Rico).—The Secretary of State for Foreign Affairs has been informed by H.M. Ambassador at Madrid that the Spanish Government have invited tenders for the construction and working of a telephone system in Mayagüez, Puerto Rico. The date fixed for the consideration of tenders is October 8, and such particulars as have been received may be inspected at the Commercial Department of the Foreign Office between the hours of 11 and 6 daily.

Dewsbury.—Tenders are invited by the Governors for the wiring and fitting of the Dewsbury and District Technical School. Copies of specifications may be obtained from the Secretary on

Digitized by Google

payment of £1. 1s., which will be refunded on return of same, accompanied by a bona fide tender. Plans may be seen at the office of the Secretary, from whom any further information can be obtained. Sealed tenders must be sent to Mr. P. F. Lee, secretary, endorsed "Electric Lighting," by 22nd inst.

Mexico.—The municipal authorities of the city of Mexico are prepared to receive proposals for the street lighting by incandescent lamps for a period of eight years. Tenders should be sent in by August 31. The Secretary of State for Foreign Affairs has received from the British Consul at Mexico a pamphlet issued by the Municipal Council of the city containing particulars as to the tenders, and this may be seen on application to the Commercial Department of the Foreign Office between the hours of 11 and 6. The plan as laid out accounts for 480 arc lamps of 2,000 c.p. each, and 120 of 1 200 c p., to which are added 150 incandescent lamps.

Southampton.—The Harbour Board invite tenders for the construction and erection of four electric cranes and accessories, and also for alterations to a gantry of an existing crane, on the Town Quay, Southampton. Specification, with two general drawings attached, may be obtained on and after 20th inst. from Mr. A. H Skelton, clerk, Town Quay, Southampton, upon payment of £3. 3s., which will not be returned, and further detailed plans may be seen at the office of the electrical engineer, Mr. J. G. W. Aldridge, 9, Victoria-street, Westminster, S.W. Sealed tenders, marked "Tenders for Electric Cranes," should be sent to the clerk by August 31.

Jassy.—The Mayoralty of the Town of Jassy (Roumania) has given notice that on August 23, 1896, old style (by our reckoning September 4), tenders will be received, for the second time, in the hall of the Municipal Council, for "the installation of a frigorific hall, electric light, and various accessories requisite for new public slaughter-houses. Offers must be in accordance with the specification, the conditions of contract, the special conditions, and the plans deposited in the offices of the director of the slaughter-house works, where particulars may be obtained." Tenders are to be enclosed in sealed envelopes, marked "Offre pour l'installation de la Hall Frigorifique," and senders of tenders must abide by articles 68-79 of the Roumanian Public Accounts Act. All tenders and supplementary documents must be in either the Roumanian or French language.

Bath.—The Corporation invite tenders for the supply and erection of the following plant:—Section A: Boiler and fittings, feed pump, etc. Section B: Steam alternators, oil-filter, fittings, etc., steam, exhaust, feed, blow-off, and sundry pipes, valves, etc. Section C: Mains. Section D: Crane. Section E: Arc lamps and posts. Tenderers are at liberty to tender for either section, but not for part of a section. The ground plan of plant and specification, with terms and conditions of tender and contract, may be obtained at the office of Mr. Robert Hammond, the consulting engineer, Ormond House, Great Trinity-lane, E.C., on and after the 13th inst., on payment of £2. 2s., which will be returned on receipt of a bona fide tender. Sealed tenders, marked "Tender for Electric Lighting," must be addressed to Mr. F. H. Moger, clerk, 3, Wood-street, Bath, and delivered by the 31st inst.

RESULTS OF TENDERS.

Hapton (Lancs.).—The tender of Messrs. Simpson Bros., Hapton, has been accepted for lighting the township with electricity from September 1, 1896, to April 30, 1897, at £124.

Cheltenham.—The electrical engineer has reported to the Town Council that tenders for the 15-kilowatt steam-exciter had been received as follows:

	Price with engine— Universal.	Belliss.
Siemens Bros. and Co., Limited...	£399 0 0	£348 0 0
Brush Electrical Engineering Company, Limited	347 5 0	—
Electrical Construction Corporation, Limited	333 0 0	386 0 0
Thomas Parker, Limited	—	329 0 0
	Crompton-Brush	Crompton-Bellis
Crompton and Co., Limited	335 0 0	379 0 0
Mather and Platt, Limited	(with unnamed engine)	425 0 0

It was resolved that the tender of Messrs. Siemens Bros. and Co. for the steam-exciter be accepted, the type of engine to be decided upon later on.

BUSINESS NOTES.

Great Northern Telegraph Company.—For the month of July the receipts were £24,000.

Aberdeen.—There is to be electric lighting at the Aberdeen flower show in the college grounds.

Llanelly.—The Town Council have agreed to an application of the National Telephone Company to erect poles.

Bolton.—The Town Council are endeavouring to get some system of mechanical traction adopted on the tramways.

New Address.—The Universal Electrical Fittings Company, Limited, have removed from Carver-street to Suffolk-road, Sheffield.

Copper.—It is stated that the statistical position of copper continues to be favourable to a further advance in the price of the metal.

Bournemouth.—The Town Council have adopted a resolution that the surveyor should be instructed to report on the telephone arrangements of the Council with a view to obtaining a reduction in the cost.

Ayr.—The report of the Hall Committee which dealt with the electric lighting of the town hall stage has been passed after some discussion.

Electric Construction Company, Limited.—The transfer books for the ordinary and preference shares will be closed from August 13 to 27 inclusive.

Fulham (London).—The Vestry have rejected a proposition to spend £75 to enable a committee to visit electric lighting works and dust destructors.

Western and Brazilian Telegraph Company.—For the week ending August 7 the receipts, after deducting 17 per cent., payable to the London Platino-Brazilian Telegraph Company, were £2,711.

City and South London Railway Bill.—The Extensions Bill of the City and South London Railway Company has passed the Lords, but the Commons reinserted an amendment to preserve St. Mary's Church.

Hull.—At the meeting of the Town Council a recommendation of the Electric Light Committee to put down a new station at a cost of £42,000 for the purpose of extending the electric lighting was lost by 26 votes to 23.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending August 9 amounted to £1,700, as compared with £1,578 in the corresponding week of the previous year, being an increase of £122.

Accident.—Last Friday a floor collapsed at the Anchor Works, Playhouse-yard, St. Luke's, which works are occupied by the London Electric Wire Company, and two workmen named Edwards and Reynolds were injured.

Bath.—In order to perfect the acquisition of the electric lighting works by the Bath Town Council, at a meeting of the shareholders of the electric light company the formal contract has been submitted, approved, and signed.

Bristol Tramways and Carriage Company, Limited.—The traffic returns for the week ending August 7 were £3,210. 3s. 4d., compared with £2,212. 15s. 4d. for the corresponding period of last year, being an increase of £997. 8s.

Colchester.—The Electric Light Works Committee have reported that they had received 10 applications for the temporary appointment of canvasser, and, after interviewing two selected candidates, they had appointed Mr. J. A. Kuner at £2 per week.

Taunton.—The electrical engineer (Mr. H. W. Couzens) reported at the Town Council meeting that there had been a very satisfactory increase in the lamp connections in the borough—92 lamps of 16 c.p. having been installed, and a further 84 applied for.

Eccles (Lancs.).—The Town Council have confirmed the report of the Town Hall and Electric Lighting Committee, and ordered that the seal of the borough be affixed to an agreement with Mr. Cornelius Bagot, on the subject of the town hall extension scheme.

Sheffield.—The Corporation having taken over the tramways propose considerable extensions, and are about to send a deputation to visit various lines in the United Kingdom and on the Continent, with a view to decide on the system of traction to be adopted.

Johnson and Phillips.—Messrs. Johnson and Phillips, of 14, Union-court, E.C., have written to us as follows: "We beg to inform you that Mr. Bennett Pell and Mr. James Brockie are no longer members of our staff, and shall be glad if you will announce the fact in your journal."

Electric Colliery Working.—The Youghiogheny River Coal Company, which own a large property in Pennsylvania, consisting of a number of mines, have lately put down an electrical plant, and are now doing practically all the mechanical work in five of their mines by electricity.

Ipswich.—The Electric Lighting Committee have submitted to the Town Council a long report and reports of Prof. Kennedy on proposals to light defined areas by means of electricity, but the consideration of the reports was postponed until the next meeting of the Council on October 14.

Epsom.—The Urban District Council have agreed to apply to the Board of Trade for a provisional order empowering them to provide electric light if they think fit, but its adoption is by no means decided on at present, and the Lighting Committee will be asked to report on the matter.

Bexhill.—The Urban District Council have received a letter from an electric lighting company in London asking whether the Council intended to apply for a provisional order for general or public lighting only. After a short discussion the matter was referred to the Lighting Committee.

City and South London Railway.—The returns for the week ended August 9 were £895, compared with £860 for the corresponding period of last year, being an increase of £35. The total receipts for the half-year 1896 were £5,419, compared with £5,084 last year, being an increase of £335.

Carbide Syndicate, Limited.—This is a new company, registered, with a capital of £1,200 in £10 shares, to acquire a patent for the manufacture of carbide of calcium, and to manufacture, sell, import, export, and deal in pharmaceutical, medicinal, chemical, industrial, or other preparations.

Leeds.—Through the kindness of the inhabitants of Roundhay and district, the workpeople who have been employed by the Thomson-Houston Electric Car Company on the Roundhay Park tramway have had an excursion to Scarborough. A handsome timepiece, subscribed for by the workpeople, has been presented to Mr. J. Burbridge, the manager of the tramway.

Digitized by Google

Morecambe.—The Urban District Council have resolved that application be made to the Board of Trade for consent to the purchase and transfer to the Council of the powers and property of the Morecambe Electric Light and Power Company, Limited, in accordance with an agreement dated February 10, 1896

St. James's (London).—The St. James's Vestry have decided to pay the electric lighting company £30 per lamp per annum for street-lighting for a term of seven years, 21 years being the term asked for by the company. It was stated that the price paid was 40 per cent. lower than that paid by the ordinary consumer.

Jandus Arc Lamp.—Messrs. Drake and Gorham inform us and it may interest our readers to know, that owing to the demand for a small Jandus arc lamp, consuming about two amperes at 100 volts, such a lamp has been designed, and can be seen at any time by calling at 66, Victoria-street, Westminster, S.W. The height of the lamp is 2ft. and diameter of globe 7in.

The Tavernier Motor.—Under the title of the Tavernier Safety Motor Syndicate, Limited, a company has been registered, with a capital of £3,000 in £50 shares, to enter into an agreement with A. E Tavernier. and to carry on business as cycle and carriage manufacturers and dealers, electricians, mechanical engineers. The directors are H. T. D. Sweet, A. E Tavernier, and G. W. Fardell.

Romford.—Messrs. Ind, Coope, and Co have written to the Urban District Council saying that they had been for some time in correspondence with the National Telephone Company, Limited, with a view of obtaining telephonic communication with London, but the matter seemed now to have become quite blocked. It was decided to reply that the Council would be willing to give all the assistance in their power.

Newton Electrical Works, Limited.—This is a company registered, with a capital of £30,000 in £10 shares, in order to enter into two agreements with F. M. Newton to acquire the undertaking of the Newton Electrical Engineering Works as now carried on at Taunton, Somersetshire, The directors are F. M. Newton, H N. Hickley, and L. C. H. Palairet, and the registered offices at Herbert-street, Rowbarton, Taunton.

Waterloo and Seaforth (Liverpool).—The Urban District Council have adopted the report of the Parliamentary Committee, which set forth that a plan of a piece of land situate on the west side of Brighton-road, Waterloo, between King-street and Sandon-street, having been submitted by the Liverpool District Lighting Company as the site of a proposed generating station, it was resolved that such site be approved.

The Amazon Cable.—The Aberdeen sailing clipper "Inverness," which belonged to Messrs. Richardson, Swansea, but which has been lying in Aberdeen Harbour for several months, has been sold to the Amazon Submarine Telegraph Company, and has left for London to be fitted with the necessary appliances for taking in store a cable for the River Amazon, where it is understood she will be ultimately stationed as a storeship.

Sunderland.—The Town Council have discussed an instruction to the Tramways Committee to take into consideration the desirability of the Corporation purchasing the lines of the Sunderland Tramway Company. No conclusion was arrived at. Meanwhile the company have commissioned Mr. R. P. Wilson, of 3, Prince's-mansions, Victoria-street, S. W., to prepare a report on the subject of adapting the lines for electric traction.

Northwich.—The River Weaver Trustees are negotiating for the borrowing of a large sum of money for improvements to the waterway, and something like £30,000 will be expended on two swingbridges, which will probably be worked by electricity. One of these bridges is in substitution of the present fixed town bridge at Northwich, which has subsided so rapidly of late that the salt craft have to be overladen to permit them to pass beneath.

Hastings.—The Roads Committee having received from the secretary of the Hastings and St. Leonards-on-Sea Electric Light Company, Limited, notice of the intention of the company to construct a transformer pit under the public pavement at Claremont, opposite the Claremont Library recommended that the plan be not approved, the site of the proposed pit being, in the committee's opinion, an unsuitable one, and the Town Council have endorsed this.

Cheltenham.—The result of the tenders for exciter and engine is given elsewhere. The Town Council have decided that the selection of a tender for the 170-h p. engine be made later on; that the matter of the claim against the estate of the late Mr. Chapman be referred to the town clerk to deal with; and that consideration of that part of the report dealing with the extension to Suffolk-square and the increase of pressure to 200 volts be adjourned to the next meeting.

Wakefield.—The Electric Lighting Committee of the Corporation have recommended the City Council to offer to supply the light to the new county offices at a charge of 6d. per unit, with a rebate of 2d. per unit for all consumption beyond an average of two hours' use per day of the standard consumption as determined by the rebate indicator, with an undertaking that the annual payments shall not exceed £400 for the first two years, and with power to the County Council to determine the arrangement at any time upon six months' notice.

Southampton.—The Electric Lighting Committee recommend the Corporation to apply to the Local Government Board for sanction to borrow £5,300 with which to purchase land at the electric lighting station, and also sanction to borrow £50,000 in connection with the whole undertaking. Reporting on the recent fire in St. Mary-street, the Works and Fire Brigade (Joint) Committee find that the fire brigade discharged their duties efficiently, but that telephonic communication was out of order and the water partially turned off.

Exeter.—Mr. Domville, on behalf of the Electric Light Committee, having moved in the Town Council for permission to put two experimental lamps on the slopes of Northernhay in addition to those sanctioned for the plateau, Mr. Varwell said that whilst not a shareholder in the gas company he thought gas would be preferable, because they would find that if they lighted the slopes with electricity the surroundings would be heavily shadowed. The motion was eventually agreed to.

Douglas (I.o.Man).—The Douglas Southern Electric Tramway, which is worked on the overhead trolley system, is now in working order as far as Whing line, and up to this point has been thoroughly tested by Colonel Rich and pronounced satisfactory. On Monday a labourer named Mylchreest was employed in a drain, the hole of which left only his head and shoulders above the ground. The hole was between the lines of the electric tramway, and while leaning his arm on the ground to allow the passage of a down tram another passed up and took off his arm.

Dorking.—The Urban District Council have adopted a resolution that a memorial be presented to the Board of Trade applying for a provisional order under the Electric Lighting Act, 1872, to authorise the Council to supply electricity for any public or private purpose within the area of the urban district of Dorking. It was, however, stated that the sole object in proposing the motion was that if they got the permission asked for from the Board of Trade, the Council would be able to keep the matter in their own hands and prevent any private company coming in.

London Tramways.—At the North Metropolitan Tramways Company's meeting the chairman said that he hoped the question of the purchase or leasing of the line by the London County Council would be settled in October, and the terms submitted to the shareholders. At the meeting of the London Street Tramways Company, however, it was stated with regard to the questions at issue with the London County Council that the directors were still negotiating, and it was advisable that the subject should not be discussed. So the matter stands at present.

Appointments Vacant.—The Wallasey Urban District Council want an assistant electrical engineer. Practical mechanical training and experience in erection of plant and running an alternating-current station are stipulated for as essential, and the salary is £150 a year. Application is to be made to Mr. Danger, at the Board's Offices, Egremont, before the 20th inst—The National Electric Supply Company at Preston want an assistant engineer to take charge of a shift (direct current). The salary is £120.—The Dundee Commissioners want a switchboard attendant at 35s. a week. Applications to Mr. Tittensor, the city electrical engineer.

The Electrical Company, Limited.—The combined staffs of the Electrical Company, Limited and the Calmon Asbestos and Rubber Works, Charing Cross-road, W.C., have held their third annual outing. The neighbourhood chosen was Boxhill. After luncheon at the Burford Bridge Hotel, athletic competitions were improvised on the top of Boxhill itself. Advantage was taken of the occasion to prepare a surprise for the managing director, Mr. F. T. Eggers, in the shape of a testimonial of the regard in which he is held by the employés of the two companies, all of whom had subscribed to the purchase of a handsome gold chronometer watch. The presentation was made at the close of the luncheon.

Dublin.—A child has been run over by one of the electric tram-cars, but it does not appear that either the driver or the machinery were in fault. The Clontarf Commissioners have received a letter stating that the United Tramways Company Bill had passed the House of Lords. Under the Bill the Commissioners were entitled to be paid by the company a sum of £100 per annum in respect of the maintenance of the sea-wall, the company being empowered to adopt electricity as the motive power for their line. It was the intention of the company to proceed forthwith with the equipment of the line as an electric tramway. The Commissioners expressed their satisfaction at the manner in which the matter had been terminated.

Newport (Mon.).—At the meeting of the Town Council Mr. G. H Llewellyn brought up the report of the Electricity Committee, which showed that there were now 9,252 lights in use as against 8,840 in May, and that after paying working expenses, but without providing for repayment of interest and sinking fund, there was a profit for the year ended March 25 of £180. Mr Proctor Eeles was delighted to find that the light was on the road to being self-supporting, and enquired whether the total number of lights included those installed in public buildings. Mr. Llewellyn reported that the whole of the lamps in use, whether public or private, were included, but he could not give the proportion in public buildings.

Fowler-Waring Cable Company.—We are informed that the National Telephone Company have just placed a contract to the value of nearly £100,000 for dry-core telephone cables with the Fowler-Waring Cables Company, Limited. The company's factory at North Woolwich has recently been equipped with a most complete plant for the manufacture of rubber and allied substances, and for the insulation of rubber-covered wires and cables. These, together with every description of mechanical rubber goods, will now be added to the manufactures of the company. Mr. Alfred E. Mavor, who has been general manager since the formation of the company, becomes technical director. Mr. J. A. Blackwood will succeed to the secretaryship of the company in place of Mr. B. J. Diplock, who is resigning the position.

Dewsbury.—From the Corporation accounts for last year, up to March 31, it appears that the electricity supply accounts show an income of £1,893. 17s. 2d. for electricity, £37. 18s. 8d. for meter

Digitized by Google

rents, and £12. 13s. 3d. for lamps, etc —total, £1,944. 9s. 1d. The expenditure was—generation of electricity, repairs, and main tenance, £717. 15s. 1d. ; distribution of ditto, £127. 8s. 4d ; rent and rates, £66. 18s. 8d. ; management expenses, £371. 3s. 10d. ; and insurance, £6 13s. 9d.—leaving £654. 9s. 5d. to be carried to net revenue account and balances. On net revenue the figures show that whereas there was an adverse sum of £806. 1s. 4d. as exhibited in last year's abstract, the amount has been reduced to £385. 7s. 3d. Turning to the balance-sheet, the assets are set down at £22,275. 0s. 1d., and the liabilities at £21,666. 12s , leaving a surplus of £608. 8s. 1d. Since the accounts were made up there has been a large increase in electric lighting, and the figures for next year will therefore probably be more favourable.

Waterloo and City Railway.—It is stated that the contractors expect to come out into daylight with their shield near Waterloo Station almost immediately. The work at Waterloo Station, which is of considerable magnitude and difficulty, was let to Messrs. Perry and Co. in January last. The work passes under the general offices of the company and below several of the piers supporting the arches on which Waterloo Station is built. Both offices and piers have to be underpinned to a considerable depth, and other operations requiring great care have to be carried out. The work has made very good progress, and as the water in the foundations is considerably less than when the works were commenced, it is believed that a like rate of progress will be maintained in the future. The station at the Mansion House will be constructed in two storeys, the first 12ft. underground for foot passengers, and from it arrangements will be made for descending 40ft. or 50ft. to the railway. The trains to Waterloo will start from the eastern end of Queen Victoria-street, and the station will communicate with the general foot-passengers' subway.

Brockie-Pell Arc Lamp, Limited.—This Company was registered on July 22 by Ashurst, Morris, Crisp, and Co , 17, Throgmorton-avenue, E.C., with a capital of £80,000 in £1 shares. The object is to adopt and carry into effect an agreement expressed to be made between William Shrimpton, The Associated Underwriters, Limited, and James Brockie and B. Pell, and the Company, and to carry on business as manufacturers of and dealers in electric arc lamps, incandescent lamps, etc., to carry on the general business of an electric lighting company in all its branches ; also as metal founders and workers, smiths, carpenters, builders, and merchants. The signatories are : J. A. Fuller, 50, Chatterton-road, Finsbury Park ; A. T. Bucknall, 17, Alexandra-road, N.W. ; A. D. Z. Lawson, 338, Romford-road, Forest Gate; E. Wyatt, 11, Highbury-crescent, W. ; W. H. May, 38, Cornwall-road, Brixton ; A. Eldridge, 36, Spencer-street, Hatton-road, Canonbury ; E. T. Church, 41, Coplestone-road, Denmark-park ; and the first directors—of whom there shall be not less than three nor more than seven—are to be elected by the signatories, with a qualifica- of £200, and remuneration for the chairman £350, vice-chairman £300, and ordinary directors £250 each per annum.

Callender's Cable Company.—Under the title of Callender's Cable and Construction Company, Limited, a company has been registered, with a capital of £100,000 in £5 shares, in order to adopt and carry into effect an agreement made between Callender's Bitumen, Telegraph, and Waterproof Company, Limited (the old company), and the liquidators thereof, for the acquisition by purchase or otherwise, as a going concern, of the business of electrical engineers, electricians, general engineers and contractors, manufacturers of and dealers in railway, tramway, electric, and other apparatus, etc , to develop and extend the said business in all or any of its branches. The signatories are G. Carr, 10, Belmont-road, Ilford ; G. M. Callender, Ormistone, Erith, Kent ; W. D. Reid, 25, Criffel-avenue, Streatham-hill ; S. C. Lambert, Kyrle road, Clapham Common ; C. W. Clarke, 94, Eversleigh-road, Lavender hill ; T. Petersen, 119, Worple-road, Wimbledon ; E. Thompson, 77, St. James's-road, Upper Tooting ; and the first directors, of whom there shall be not less than three nor more than seven, are H. Drake, W. O. Callender, D. P. McEwen, G. A. Elliott, W. M. Mackenzie, and T. O. Callender, with a qualification of £500 and remuneration of £900 per annum and 2½ per cent. of the net profits, divisible The registered offices of the Company is 90, Cannon street, E.C.

Manchester.—Mr. Alderman Higginbottom has called attention to a report by the Town Hall Committee that they had arranged with the National Telephone Company for the wiring and fixing of new telephone instruments in the town hall, and said he hoped those new instruments would be removed and the old ones brought back. A more abominable system than the existing telephonic system of Manchester could not be conceived by any business man. Business men felt now that they had better spend 6d. on a telegram at once than have anything to do with the telephone, which under the disgusting system now in operation simply led to a waste of time. Yet this was the system that the chairman of the company said Manchester ought to be proud of. Mr. Wilson pointed out that the new telephonic system had not got into working order yet. To make such charges as Mr. Alderman Higginbottom had done was decidedly premature. Mr. Alderman Milling said he was assured on the best authority that when every subscriber had been connected with the new arrangement the system would really be found to be perfection. Two-thirds of the underground cables were now laid, and 1,150 subscribers were already in connection with the new cables Mr. N. Bradley said the city would never get either cheapness or efficiency so long as there was a monopoly of the telephones, and the subject was then passed over.

Mitchelstown (Ireland) —At a meeting of the Board of Guardians, Mr. Fitzgerald said that at last Board meeting they had under consideration the question of the area of taxation for a scheme of public electric lighting which the Guardians proposed to adopt for Michelstown. At last meeting the Board referred his (Mr. Fitzgerald's) proposal of an area of taxation to the local committee of townspeople who had charge of the scheme for the town ratepayers. He had communicated the views of the Guardians to a meeting of the Town Committee, and the result of their deliberations was that they had adopted a scheme of electric lighting offered by Mr. Webber, the landlord of the Kingston estate. By this arrangement Mr. Webber agreed to light the streets of the town by electricity for £75 per year. Mr. Webber proposed to have 42 electric lamps, and to supply the light from sunset to midnight, and would enter into an agreement with the Guardians as local executive authority under the Electric Lighting Act, 1882, to supply the light and manage and work the scheme for a period of 22 years It was proposed to borrow from the Board of Works a sum of £450 for the purpose of erecting lamps, plant, etc., which would be all handed over to Mr. Webber. It was estimated that by adopting the proposed area, the annual assessment for the light would be about 6d. in the pound on the valuation. Mr. Fitzgerald's report was adopted.

Altrincham —The Urban District Council have received the following letter from Messrs. Andrews and Butterworth, Manchester : " We write you on behalf of a syndicate who are desirous of obtaining powers of laying down a system of tramways along the main road from Stretford to Peel Causeway, and working the same by means of electricity. We understand that concessions have already been granted by your authority for electric light for the district, and we may say that the scheme for electric tramways would be worked in conjunction with the system for electric lighting, either by the same company or an arrangement for supplying power. If you are prepared to afford facilities for the laying and working of the tramways it would enable the price of electric light to be reduced from 8d. per B.T. unit, the maximum price allowed, to 4d., and probably 3d. per unit. The syndicate would be prepared to give the local authority power to acquire their interest and property after a certain period. If the proposal is carried into effect we think the lighting of the main road would be carried out by the syndicate at a nominal cost to the local authorities, thereby affording a large saving to the Council. We should be glad of an opportunity to attend and more fully explain the scheme to the members of your Council." The clerk was instructed to ask Messrs. Andrews and Butterworth to attend a special meeting of the Council, as suggested.

Shooter's Hill (London).—The electric lighting, telephones, and fire-alarms at the Brook Hill Hospital of the Metropolitan Asylums Board have been arranged by Prof. Kennedy. The hospital is lighted throughout by electricity. The plant for this consists of three steam-engines and dynamos, of 50 i.h.p. each, and a storage battery of 64 cells, with a capacity of 500 ampere-hours. The current goes to a switchboard, and from there is distributed to two systems of mains, so arranged that the fever blocks and isolation wards are supplied from both systems, about half the lights being connected to each system. The remainder of the buildings are supplied from one system only. Each system of mains consitutes a complete ring. The lighting of the wards and offices is by incandescent lamps, arc lamps being used in the stores, kitchen, laundry, and boiler-house, and for lighting part of the grounds. The whole of the buildings are connected up by telephone to a small exchange placed in the superintendent nurse's office, in the centre of the hospital. Special arrangements have been made for telephoning to the ambulance station adjoining, and direct to the head office in London. A large gong placed near the centre of the buildings is connected to each of the separate blocks, from which it can be sounded in case of fire At the same time smaller gongs sound in some of the offices and the men's quarters. At the main gong an indicator is dropped, showing from which block the alarm has come.

Bradford.—The demand for electric light in Bradford is still increasing, but comparatively little is done in the way of using electricity for motive power. In the hope of stimulating the use of their electricity for motors, the Corporation committee have determined to reduce the charge for its supply for that purpose from 3½d. to 2½d. per unit. At a meeting of the Town Council, Mr. W. C. Dixon (chairman of the Gas and Electricity Supply Committee) moved the adoption of the minutes of that committee. Mr. C. E. Dowson pointed out that before long the Tramways Committee would have to consider the desirability of laying tramlines to Great Horton. He asked whether, in the event of the present tramway companies not offering to lease those lines, the present electricity works would if required be able, without any additional expense being incurred for extra plant, to supply electricity to work the cars on those lines He also asked at what price the current could be supplied if electricity were the motive power adopted. Mr. Dixon suggested that the question was perhaps a little premature, since the matter was one which would have to be thrashed out by the committees concerned. He had, however, no hesitation in saying that the electricity works would be able, if required, at the end of the present year to supply sufficient current to work tramways up both Bolton-road and Morley-street. The Gas and Electricity Supply Committee were enlarging their works, and were merely waiting for an opportunity to properly distribute electricity all over the borough. The minutes were adopted.

The Ediswan Catalogue.—We have received from the Edison and Swan United Electric Light Company, Limited, their new catalogue of lamps, which has just been issued to the public. The size of the catalogue (120 pages) is a sign of the growth of the incandescent lamp industry which for so many years was bound up in the above firm. It is worthy of note that the Ediswan lamp is holding its position in the market rather by the high

Digitized by Google

standard of manufacture than by a cutting of prices. The information given in the catalogue now before us on the point of a higher efficiency in watts per candle is not very definite. The lamp bulbs are now marked with distinctive letters, A, B, C, and D, signifying that the lamps so labelled require respectively 4, 3½, 3, and 2½ watts per candle. The price of the lamps is not varied with the efficiency, and readers are warned against taking information as to the life of lamps from single experiments. The high-voltage lamps, of which so much has been written during the past winter, are strongly in evidence. They are manufactured at present by using two filaments in series in a common bulb, and hence are directly comparable with the normal voltage lamps. The efficiency at present claimed varies from 3½ to 4 watts per candle, and the prices are reasonable. The other classes of lamps illustrated are too numerous to do more than name Thus they include lamps for series work, Sunbeam lamps, focussing lamps, and the final large class of special lamps. These latter have been designed from time to time to meet the requirements of medical men, both for surgical purposes and microscopic research. This class also includes a large number of special shaped and coloured lamps for decorative effects, including that tribute to the ancient taste of the aristocracy, the candle lamp. As a work of reference this catalogue will be of use to every electrical engineer.

Lambeth (London).—The report of the special committee appointed to consider the details of the agreement for the transfer of the Vestry's provisional order for electric lighting to Mr. Sax has been submitted to the Vestry. The committee had a long interview with Mr. Sax and his legal and engineering advisers, and the only important question appeared to be the rate at which the dust should be supplied by the Vestry to Mr. Sax. Mr. Sax objected to the rate of 9d. per ton suggested by the committee, and submitted that no sum under 1s. 3d. per ton would be satisfactory or remunerative, and intimated that the cost to other vestries was not less than 1s. 8d. per ton. After discussion, the committee increased their suggested payment to 11½d. per ton, and Mr. Sax agreed to accept that figure. Mr. Sax's solicitor had intimated that there would be no difficulty in arranging all the other terms in accordance with the report of June 24. On the report coming up for confirmation, Mr. Hubbard remarked that nothing was said as to where the dust destructor would be, and the committee seemed to ignore the question of cartage. He moved that the discussion should be adjourned until the next meeting of the Vestry, and that in the meantime a copy of the draft agreement should be supplied to the vestrymen. The Clerk said the point alluded to by Mr. Hubbard was provided for in the agreement, the site for the dust destructor being subject to the approval of the Vestry. Mr. Hooper declared that Mr. Hubbard's aim had been from first to last to wreck the scheme. Mr. Orfeur pointed out that the only points that had to be decided were purely of a legal nature, and Mr. Hubbard's motion was rejected, as were two amendments by Mr. King and Mr. Prichard, and eventually the report was adopted. The vestry clerk was then authorised to insert the necessary advertisements dealing with the transfer in the *London Gazette* and in four of the local papers.

Brighton.—The borough surveyor has reported on the application from the Telegraph Department of the Post Office requesting permission to lay in telephone wires, that it was proposed to lay the wires in pipes under the roadway from the railway station down Trafalgar-street, York-place, Brunswick-place, and the Ditchling road as far as Hollingdean-road, and from thence to the boundary of the borough by means of wires affixed to poles, such poles being erected upon the highway. He saw no objection to that portion of the work proposed to be laid in pipes under the roadway, but suggested that the route be altered by taking Station-street and Cheapside instead of Trafalgar-street, but could not recommend that permission be given for the erection of any poles within the borough as shown on the upper part of Ditchling-road. It was resolved that the postal authorities be informed that the Council will sanction the laying of the proposed underground telephone wires on the route shown on the plan submitted by the surveyor, but cannot consent for the erection of poles to carry overhead telephone wires on the Ditchling-road from Hollingdean-road to the boundary of the borough as proposed. At a meeting of the Lighting Committee it was resolved that new electric light mains be laid as under—viz : in Ann-street, from London-road to the corner of St. Peter's street, at an estimated cost of £38 ; in Grand-parade and Sussex-street, from the existing main in Grand-parade opposite North-road as far as 120, Sussex-street, at an estimated cost of £132 ; in Stanford-avenue, from the termination of the existing main to 67, at an estimated cost of £50, and that the public lamps along the line of such new mains be lighted by electricity instead of gas. At a further meeting of the committee it was resolved that an electricity main be laid in Southover-street at an estimated cost of £290, and that the existing gas lamps in that street be lighted by electricity instead of gas. These resolutions have now been confirmed by the Town Council.

Bangor (North Wales).—The following was a minute of the meeting of the Electric Lighting Committee : "It was mentioned that Mr. Medhurst had submitted an account for £100 for his services in connection with the electric lighting scheme. It was resolved that the Council be recommended to pay same. The notices received from the Bangor Electric Supply Company and the Manchester Edison-Swan Company were considered, and it was resolved that, inasmuch as the Council have decided to apply for a provisional order for the supply of electricity within the borough, they (the Council) are unable to comply with the request of the companies." Upon this coming up for confirmation in the Town Council, Mr. W. Bayne asked if a resolution had not been passed by the Council to the effect that a sum of £50 should be paid to Mr. Medhurst in full discharge of all claims in case the electric light was not proceeded with. Mr. T. Lewis said that a resolution was proposed by Dr. Grey Edwards, seconded by Mr. R Davies, and carried *nem. con.*, on September 20, 1895, providing that, if the Council obtained the necessary powers to proceed with the electric lighting scheme, Mr. Medhurst be appointed engineer at a remuneration of £650, this sum to include charges for plans specifications, and superintendence of works. If, however, the Council, owing to unforeseen circumstances, did not proceed to obtain the necessary powers that Mr. Medhurst be paid the sum of £50 in full discharge of all claims. Mr. W. Bayne failed to see how they could adopt the committee's recommendation in the face of the resolution referred to. He moved that the matter be referred back to the committee. Mr. Foster, the mover of the committee's report, said the extra £50 was accounted for by Mr. Medhurst having to prepare five or six plans instead of one. Mr. R. Davies said that Mr. Medhurst had been instructed to prepare additional plans subsequent to the meeting of the Council to which Mr. Lewis had alluded. Ultimately Mr. Bayne's amendment was agreed to, the remainder of the committee's minutes being confirmed.

Dundee.—At a meeting of the Gas Committee of the Town Council the question of the cost of electric lighting lamps in High street has been under consideration, and a remit was made to the interim electrical engineer to report on the cost, and state whether the electric lamps should be dispensed with or improved. He was also instructed to report with reference to the electric lighting of public lamps in other towns. A report was submitted by the interim engineer on the lighting area. He said the present lighting system was installed over three years ago, when plant for supplying 10,000 lamps was put down. At present there were about 17,000 lamps connected with their mains. No additional mains had been laid in the Wellgate district since the commencement, and there were several complaints from consumers last winter regarding the pressure. During the present year additional lamps had been connected, so that heavier mains were most urgently required to cope with the demand. Under existing circumstances it would not be possible to keep within the limit prescribed by the Board of Trade. He would recommend that the Overgate and Whitehall-street mains, which were overloaded, be also attended to. Enquiries had been made for supply in Dock-street and South Tay-street, in neither of which streets were there mains laid, though they were within the area of supply. He would urge that all further supplies be given at a pressure of 200 volts. This would be a great benefit to them, and would result in a saving of from 20 to 30 per cent. of copper on any further extension. By adopting 200 volts as the standard pressure for future supplies, the work of changing over to the three-wire system would be greatly simplified. The proposed increase of mains would mean a total cost of £1,047, as follows: Wellgate and district, £525 ; Whitehall-street, £32 ; Overgate, £210 ; Dock-street (200-volt supply), £110 ; and South Tay street, £170. The report was approved generally, and the clerk was instructed to advertise for cables for the Wellgate district, Overgate, and Whitehall-street. The committee have agreed to recommend that Mr. W. A. Tittensor, interim electrical engineer, should be appointed electrical engineer at a salary of £200 per annum. The committee were of opinion that no assistant electrical engineer would be necessary, but that a remit should be made to the convener and the electrical engineer to adjust and increase the subordinate staff so far as necessary.

Bury St. Edmunds.—It will be remembered that at their former meeting the Town Council adopted a scheme for lighting the whole of the streets of the town with incandescent lamps and supplying private lighting within a restricted area, the system adopted being a continuous-current one on the three-wire system with supply at 220 volts. There was considerable opposition, but an effective debate of the matter on its merits was hampered by the fact of a large number of the town councillors being interested in the local gas company. The Electric Lighting Committee were unanimous in favour of the scheme, and a poll or some other means of ascertaining the feeling of the ratepayers was refused. The subject came up again on Tuesday, when Alderman Lake remarked that at the former meeting Alderman Gough suggested that he was prepared to give a guarantee that the electric lighting of the borough should not be any expense to the ratepayers whatever. He expressed his willingness to take the matter over, holding himself liable for any possible loss, and receiving whatever profit might accrue from the adoption of the scheme The idea had, however, been ridiculed ; but he (Alderman Lake) would ask whether it was not quite possible to form a small company to take up the matter ? If the ratepayers were so foolish as to allow them to take the profits, he had no objection. He was quite prepared to be one of a small company willing to take over the electric lighting of the town, guaranteeing the ratepayers against loss for 20 years, and taking the profits during that time. He should like to know whether members of the Town Council could legally become members of such a company. If they could, then there would be no doubt as to the necessary guarantee being forthcoming, and the members of the Ratepayers' Association would be relieved from the need for parading in front of the Mayor's premises on the following Thursday evening. Of course, others besides members of the Town Council would constitute the company. Mr. Turner did not think the Town Council could recognise a company formed of its own members. He had received an intimation that one or more contractors were willing to undertake the same thing as Alderman Lake had proposed. Mr. Hooper did not think members of the Town Council were debarred from becoming

Digitized by Google

associated with an electric lighting company any more than members of the Town Council being connected with the gas company. The Town Clerk (Mr. C. E. Salmon) felt that the point involved was one of grave importance, and wished for time to carefully consider it. He would consult his parliamentary agent.

Plymouth.—Mr. Rider's report we give in full elsewhere. On its consideration by the Town Council, Mr. Willoughby moved the adoption of the committee's recommendation that application should be made to the Local Government Board to borrow the sum of £45,000 to carry out the work. Application has already been made for sanction to borrow £1,000 for the same purpose. Mr. Elliott questioned whether they would be justified in spending two and a half times as much in lighting the town with electricity as they were now spending on gas. Whilst he entirely agreed with the principle, he thought they as a Council should have some idea as to the total cost before sanctioning a portion of it. Mr. J. Yeo said that whilst for business purposes the electric light would be a good thing, he questioned the wisdom of incurring a cost of £1,184 for public lighting when that was done at the present time for £475. Mr. J. Willoughby said the experience of other towns was that the more electric light was used the greater was the consumption of gas. There could not be a doubt that the lighting of Plymouth by electricity would make it one of the most attractive places in England; and it should not be forgotten that the more the light was used the cheaper it would become. It was calculated that there would be a saving ultimately of £4,000 per annum by the substitution of electric for horse power for the trams. Mr. Page reminded the Council that it was shown that the loss on the public lighting would be nearly £700 per annum, and moved that the further consideration of the minute be deferred until after November 9 next. There was no seconder to this. Mr. J. Willoughby said the buildings it was proposed to erect would be sufficient to permit of the scheme being extended all over the town, but the plant proposed would not. It would be possible to supply the hotels and public buildings with the light up to a maximum of 12 000 lights. The Mayor said he had just had a consultation with the town clerk, and found that their electric lighting powers would soon expire. It was therefore necessary that some definite action should be taken without further delay. It would be an extraordinary thing if they, as a Council, were to pass a vote of want of confidence in themselves. Mr. J. Willoughby said he never expected to see every part of Plymouth lighted with electricity. There was not a town in England where that was done. Mr. Page seemed utterly unable to see that what he imagined was a loss on the public lighting was really no loss at all when they considered that in 30 years the property would be their own. The recommendation of the committee was approved.

Glasgow.—The Corporation have discussed a proposal by the Tramways Committee to equip the route from Mitchell-street to Springburn with electric cars propelled on the overhead system. When the minutes were put before the meeting, Mr. Paton, the convener, explained that the proposal had only been carried in committee by his casting vote. He had subsequently reconsidered the matter, and had come to the conclusion to move that the matter be sent back to the committee for further consideration. Mr. Angus Campbell opposed this, and the Lord Provost said that not one member of the committee who saw the working of the electric tramways on the Continent had gone back from his views, but the committee did not now say that they considered the Springburn route the proper route on which to try the system, or that the present was the proper time. Personally, he thought the Springburn route was the proper one on which to try the experiment, but he did not think it was the proper time. There was no hurry, and he thought they should not refuse the request of the convener, but allow him to take the matter back. Mr. W. F. Anderson moved that further consideration of the proposal should be delayed for six months, and Bailie John Murray seconded this. Mr. J. H. Martin moved the amendment which he made in committee—namely, that further consideration of the matter be delayed. Bailie Jack seconded, and Mr. Primrose supported delay. They were, he thought, on the eve of great developments in electric haulage. Perhaps within six months the conduit system might be demonstrated to be the best. Bailie Burt said that the present cars were at certain times of the day very much overcrowded, and that of all the mechanical methods of traction the one which presented fewest objections was the overhead system. Mr. Paton said that when the Corporation took over the tramways it was on the express understanding that they were to introduce mechanical motors as soon as possible. Horses were being superseded by other motors, and the overhead wire system was the one most generally adopted. Cable haulage was making no progress. All over the Continent and America it was electric tramways or nothing. The public in this country, unfortunately, did not know much about electric traction, and a number of bogeys had been held before them. Possibly the committee had made a mistake in going too rapidly at the thing when rather they should have been educating the public. In the circumstances, he thought they would be doing wise in sending the matter back again to the committee. Mr. Campbell subsequently withdrew his motion, and on a vote being taken, as against the other motions, Mr. Paton's motion to have the subject sent back was carried by a large majority. The Sub-Committee on Halls recommended that St. Andrew's Halls should be lighted by electricity, and Bailie Alexander, in moving the adoption of the minutes, explained that the cost was estimated at £1,647. He asked that the committee should have full powers to take the lowest offer for the work. This recommendation was adopted. The sub-committee on electric lighting have reported, with reference to the resolution to experiment with eight of the arc lamps at the west end of Sauchiehall-street, that they had approved of a design by Messrs. Macfarlane and Co. of an arm and pendant projecting 3ft. only from the pillar, which will admit of the lamp being made a fixture, and the Town Council have passed the report. The central railway was recently opened for passenger traffic. The carriages are at present lighted with gas, but in the course of a few days an experiment is to be made with electric lighting.

Blackburn.—The Town Council have decided that application should be made to the Local Government Board, in pursuance of the provisions of the Electric Lighting Acts and of the Blackburn Electric Lighting Order, 1890, for their sanction to the borrowing by the Corporation of the further sum of £15,000 for electric lighting purposes. At the half-yearly meeting of the Blackburn Corporation Tramways Company. Limited, Mr. R. A. Jackson (the chairman), in introducing the question of electric traction, remarked that some of the directors had inspected the gas traction in use on the Lytham to Blackpool tramway, and had come to the conclusion that such a motive power would not do for Blackburn. Mr. Jackson gave details of the cost of the present motive power of the company, stating that last year the cost on the Preston-road section, including all expenses, was 9·84d. per mile, Witton 9·21d., and the steam section 7·08d. The provision of motive power alone on the steam section was 2·29d. per mile run, Preston-road section 6·16d., or an average for the two of 4·29d. per mile. He and another director had visited Bristol and inspected the electric tramway there, which had run without a hitch since it had been got into proper working order. The directors had had interviews with the Blackburn Corporation with regard to the use of electricity as a motive power for their cars, but at present they had no offer from the Corporation. As the matter stood at present, the Corporation did not want to go into it again unless the directors of the company were prepared to enter into a fixed agreement. The Corporation had offered to supply them with electricity at 3d. per mile run, up to 130,000 miles; but if the distance were increased to 180,000 miles, then they were prepared to decrease the price to 2½d. per running mile. The Corporation undertook to bond the rails, to put the necessary plant down in the depôts, and to erect the standards in the streets; in fact, the Corporation would do everything except find the cars. The company would therefore have to provide their own cars and to make any alterations that were required in the passing places and in their own depôts. The difference between the cost of their present motive power and the cost of electric traction he estimated at £650 a year in favour of the latter. The cost of the cars it was estimated would be about £700 each. Replying to a shareholder, who asked if the directors were unanimously in favour of electricity, the Chairman said that the opinion of the directors was that the matter should be allowed to stand over for a year or two. Mr. Beesley (a director) thought that the proper time to utilise electric traction was when their present engines had been worn out. Mr. Magerison (another director) was of opinion that the question of at once adopting electricity as a motive power deserved serious consideration, but they ought to pay off the remaining £8,000 debenture-holders before they talked about borrowing money for the purposes of electric traction. Eventually it was decided to defer the matter for 12 months, but the directors were empowered to call a special meeting of shareholders at any time they considered necessary.

Fort William (Inverness).—The price of gas supplied to Fort William is said to be probably the highest in Scotland, and the quality has been complained of. Consequently, four or five years ago, the question of lighting the place with electricity received consideration, but the proposals then made obtained no great support, and the attempt was abandoned. About a year ago the proposal was renewed. At first there seemed no good prospect of raising the necessary capital as the sum required was rather large for local appropriation, but was small for ready acceptance in the open money market. About the beginning of the present year a limited liability company was formed under the name of the Fort William Electric Lighting Company, Limited, The necessary capital—£7,000—was subscribed, and by the beginning of March a commencement with the preliminary works was made. The company offers to supply electric light at its dearest at a cheaper rate than has been paid for gas, and for power during the day at half-price The progress of the works has already been noted in these columns, but the following gives some additional information. The source of power which first suggested itself was the River Nevis, which falls into Loch Linnhe close to the town, and on which, at a distance of less than a mile, there is a suitable fall. This was the place originally proposed as the position of the turbines, but when the owner of the salmon fishing on the river was approached on the subject his conditions were found impossible. Another source of power had therefore to be looked for. This was found in the River Kiachnish, which falls into Loch Linnhe, about three miles below Fort William. The stream itself is considerably smaller than the Nevis, but the construction of a lade of about 1,200 yards allows a fall of 120ft., and brings the application of the power by so much nearer the town. At this point a building has been erected in which are placed the turbines and dynamos required for producing the electricity, which is conveyed thence by an overhead line to the central station at Fort William, from which it is distributed by cables, partly overhead and partly underground. The poles for the overhead cables are placed at a distance of 60 yards from each other. The cables are of 19 strand 13 gauge copper wire. The total length of cable is about 14 miles. The power is applied by means of

Digitized by Google

two 60-h.p. vortex turbines supplied by Gilkes and Co., Kendal, which drive two continuous-current dynamos by Laurence, Scott, and Co., Norwich. The station at Fort William contains an accumulator of 164 cells, E.P.S. central-station type, with the requisite switchboard for distributing the current. The lamps used are 16 c.p., voltage 150. The cost to the consumer is to be 9d. per Board of Trade unit from an hour before sunset till nine o'clock in the evening, and for the rest of the 24 hours 4½d. per unit. The town is, in the meantime, to have four arc lights of 1,000 c.p. each, and over 60 incandescent lights, each of 16 c.p The total cost for lighting the streets is for the present £180 per annum. Terms have also been arranged on which the street-lighting may be extended. Arrangements have already been made for the electric lighting of the principal shops and hotels, the churches, and other public buildings, and a number of private houses. The first trial of the new light was made on Monday night in the Station Hotel, and was in all respects successful. It will be some time yet, however, before the streets can be lighted and the light generally supplied. The chief engineer of the work was Mr. R. T. Yorke, with Mr. H. W. Bagot and Mr. A. Cottrill Dormer assistants. The lade was laid out by Mr. John Paterson, Fort William, and the contractor for it and for the turbine-house was Mr. A. Bremner, Fortingall. The contractors for the accumulator-house at Fort William were Messrs. J. and P. Maclachlan, Larbert.

PROVISIONAL PATENTS, 1896.

AUGUST 4.

17161. **The manufacture of an improved active material for the plates or electrodes of electric accumulators.** Siegfried Hammacher, 11, Southampton - buildings, Chancery-lane, London.

17180. **Improvements in combined typewriters and electro-telegraphic transmitters.** William Lloyd Wise, 46, Lincoln's-inn-fields London. (World Flash Company, United States.) (Complete specification.)

17187. **An improved electric cable or conductor for electric fire or other alarm systems.** Charles Darwin Tisdale and John Duncklee Gould, 45, Southampton buildings, Chancery-lane, London. (Complete specification.)

17200. **Improvements in and in connection with supports for electric lamps.** William Lloyd Wise, 46, Lincoln's-inn-fields, London. (Frank E. Kinsman, United States)

17203. **Improvements in methods and means for electric regulation of power.** Horace Bigelow Gale and Charles Trotter Thompson, 24, Southampton-buildings, Chancery-lane, London. (Complete specification.)

17222. **Improvements in portable telephones.** Charles de Ricaris, 45, Southampton-buildings, Chancery-lane, London.

AUGUST 5.

17257. **Improvements in electric meters.** Emile Batault, 21, Ely-place, Holborn-circus, London.

17338. **Improved device for automatically throwing into circuit reserve electric lamps, motors, or resistances in case of breakdown, and for protective purposes.** Edmund Jokl Wilhelm Maximilian Christian and George Kemp 46, Lincoln's-inn-fields, London.

AUGUST 6

17346. **Improvements in or connected with secondary or storage batteries.** Ferdinand Francis Ernest Heyse and William Hopkin Akester, 57, Chancery-lane, London.

17363. **Improvements in electromotors.** Rankin Kennedy, 33, Gladstone-street, Leeds-road, Bradford.

17389. **Improvements in electric rock drills, caulking tools, and other reciprocating machines.** Albion Thomas Snell 52, Chancery-lane, London.

17395. **Improvements in magnetic cut-outs.** Leonard Andrews, 166, Fleet-street, London.

AUGUST 7.

17436. **Improvements in compasses.** Thomas Bassnett, 4, Clayton-square, Liverpool.

AUGUST 8.

17557. **Improvements in continuous-current dynamo-electric generators and motors.** Sebastian Ziani de Ferranti, 27, Charterhouse-square, London.

17558. **Improvements in dynamo-electric generators and motors.** Sebastian Ziani de Ferranti, 27, Charterhouse-square, London.

17563. **Improvements relating to electric traction.** Thomas Meacock, 18, Southampton-buildings, Chancery-lane, London.

17577. **Improvements in electrical measuring instruments.** George Keith Buller Elphinstone, 101, St. Martin's-lane, London.

17578. **Improvements in electrical signalling apparatus.** George Keith Buller Elphinstone, 101, St Martin's-lane, London.

17579. **Improvements in electric railway systems.** Daniel MacLaughlin Therrell, 23, Southampton - buildings, Chancery - lane, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, January 9, 1896, being date of application in United States.)

17608. **Improvements in means or apparatus for effecting the electro-deposition of zinc or other metals upon tubes or other circular or analogous objects.** The Cowper-Coles Galvanising Syndicate, Limited, and Sherard Osborn Cowper-Coles, 47, Lincoln's-inn-fields, London.

SPECIFICATIONS PUBLISHED.

1895.

11752.* **Electro-deposition of gold and silver.** Andreoli. (Amended specification.)

14438. **Electrical annunciators and pushes or calling devices connected therewith.** Stamm.

15889. **Construction and working of electric arc lamps.** La Société les Fils d'Adolphe Mougin. (Date applied for under International Convention, February 11, 1895)

16450. **Stage or like arc lamps for alternating currents.** Sykes.

17058. **Periodically ringing bells and sounding whistles, syrens, or the like, and registering the same, and electrical apparatus therefor.** Berry.

17400. **Permanent way, electric conduits, and conductors of electric tramways.** Wood and Brodie.

17481. **Electroliers.** Best.

21638. **Electrical switches.** Fielding.

1896.

8163. **Alarm clock and apparatus for automatically operating electric signals at definite hours.** Mesmer-Weber.

9480. **Collector for conduit and similar electric railways and the like** Crotz Allen. and Kelly.

11419. **Devices for electrically lighting the wicks of oil lamps.** Fitzpatrick. (The Empire Self-Lighting Oil Lamp Company.)

13074. **Manufacture of electrical resistances.** Marquand and Lowdon.

13079. **Dry batteries and the like.** Thompson. (Lesenberg.)

13295. **Electrically-controlled railway signals.** Thompson. (McBrien, Wayland, and Fleming.)

13521. **Manufacture of carbon anodes for electrolytical processes.** Jensen. (Cappelen and Cappelen.)

NOTES.

Obituary.—The death is announced of Prof. H. A. Newton, the mathematician, of Yale University in America.

Personal.—Mr. J. Snell, of St. Pancras, is to be recommended to the Sunderland Town Council for the post of electrical engineer for the Wearside borough.

"Electron."—We have to acknowledge from Madrid the receipt of copies of *Electron*. The publication is a comparatively new one, and is devoted to the interests of the Spanish telegraphic service.

Matrimonial.—The marriage of Mr. T. M. Furniss, formerly electrical engineer at Larne, and now with Messrs. J. C. Howells and Co., of London, took place at Carlow on Tuesday last. The bride was Miss M. E. Burne, of Ballinacarrig.

The Enclosed Arc.—An application for an American patent has been filed by Mr. O. S. Lyford, of Chicago, for an arc lamp with an enclosing chamber for the carbon electrodes normally sealed from the external air, but with a porous or fibrous diaphragm for securing the equalisation of any substantial difference between the external and internal pressures.

East London Technical College.—We have to acknowledge the receipt of the calendar for next winter's session of the technical college in connection with the People's Palace at Whitechapel. Attention is called to the fact that considerable developments have been made, more especially in extending and systematising the instruction in the day classes.

The Jacques Cell.—From experiments which have been made in America by Mr. C. J. Reed before the Franklin Institute, it appears that at any rate a large portion of the current obtained from the carbon, hot soda, and iron battery of Dr. Jacques is thermoelectric in its origin. It seems that a current is still obtained if the carbon is replaced by a metal that is not oxydised and a gas containing no oxygen is used to "aerate" the hot soda.

Cairo Tramway.—We have already briefly noted the opening of the Cairo electric tramway by Fakhry Pasha, the Minister of Public Works. From the Egyptian *Journal Officiel*, which is now to hand, it appears that the line runs from Bulaq to the Citadel. There will be two classes, and the fares will four, six, or eight milliémes, according to distance, for second class, and six, eight, and ten milliémes first class. A milliéme is somewhat less than a farthing. Officers and soldiers will in general be carried at about half fares.

Publications Received.—We have to acknowledge the receipt of the August issue of the *Journal* of the Chemical Society. There are more than 230 pages by Dr. Perkin "On Magnetic Rotatory Power, especially of Aromatic Compounds." We have not at present had time to find out what it all comes to. Several of the abstracts relate to matters connected with electrolysis, and some of them may possibly be drawn on to supply subjects for these notes. From Chicago we have received the *Journal* of the Western Society of Engineers.

Too Successful.—The position of the Hull Electric Lighting Committee is not exactly a pleasant one just at present. The electric lighting is a success. The committee have already allowed about 3,000 more lamps to be attached to the station than the station was originally estimated to supply, and they are still receiving additional applications for current. Their difficulty is that the Council cannot agree as to allowing them to make extensions. Meanwhile, what is a poor committee to do except keep on reporting? Only, unfortunately, one cannot generate and supply current with reports alone—machinery and mains are also necessary.

The Metric System.—The Bill which was introduced (not to be passed) by the President of the Board of Trade at the end of the session, and which it is intended to get through Parliament next session, will legalise the use of the metric weights and measures, and contain in its schedules tabular statements of the relation of those weights and measures to those in use in this country at the present time. It appears that it was the Weights and Measures Act of 1878 which "illegalised" the previously legal but unused metric weights and measures.

The Telegraph in Ceylon.—We understand from an Indian contemporary that the telegraph and telephone service in Ceylon is not what it should be. The blame seems to lie in one of two directions. The first is the climate, and the second the organisation of the staff. The quick growth of the vegetation and the salt spray brought inland by the south-west monsoons play havoc with the insulation of the overhead wires. The climate may, at the same time, affect the operatives, but we understand that improvements in their outfit are being rapidly carried out, and that several orders for stores may shortly be placed in England.

Trolley Wire.—A way of stringing trolley wire devised by Mr. Walker is stated by the *Electric Railway Gazette* to be used on the Sioux City line. The reel containing the wire is placed on the front platform of a car, so that it may revolve and put a tension on the wire. From there the wire passes over a wheel on the roof, where the men standing on the platform can readily attach it to the supports. The wire is live and the current for propelling the car passes through it. By this means it is stated that it is possible to string the wire at the rate of about a mile a day. To our European notions it looks, to put it in the mildest way, just a little bit risky.

St. Mary's Woolnoth.—Before Parliament rose the House of Lords agreed to the Commons' amendments to the Lords' amendments to the Bill of the City and South London Railway Company. In the Commons, the chairman of the committees intimated that the railway company had consented to take the Bill as amended. The upshot of it all is that the troubles of the company, caused by the admirers of St. Mary's not knowing their own minds, have come to an end at last, and that church will remain—with a railway station underneath it. Although it is now all over, this has not prevented any amount of correspondence on the subject in the *Times*.

Neglected Talent.—The bringing out of motorcart companies seems just at present to be very much in vogue. In case the supply of inventors and motors runs out it may be well to mention there is at the present moment one in Coventry workhouse which is available to be exploited. It was, indeed, suggested that the Guardians should bring the invention out, doubtless for the benefit of the ratepayers, but the Local Government Board is known to hold old-fashioned ideas on the subject of corporate enterprise, and would hardly sanction a loan for the purpose. So we shall probably never see the rate collector going round and paying a dividend instead of collecting a rate from the inhabitants of Coventry.

The Wonders of Electricity.—Two of these are reported this week by the old and well-tried specialists who supply the Dalziel telegrams. The first is merely a new fleet of warships for the Japanese Government. These, though small, are thickly armoured, and though they have their screws in the middle instead of in the proper place,

Digitized by Google

being driven by electricity, naturally go 40 knots an hour. Anybody can mix up the dimensions of a ship, but an apparatus devised by Superintendent Reardon, of the Perkins School for the Blind in Boston, U.S.A., is a distinct advance. This discovery, which has been "perfected," "if it does not enable any totally blind to see, increases to a wonderful degree the visual power of those to whom ordinary aids have been almost unavailing." It does this by sending the current from a small pocket battery through an arrangement of selenium, glass, and vulcanite, and the "sight centres." After this a merely riotous meeting in Rome to protest against electric tramways falls flat.

The Trunk Line Telephones.—At the meeting of the council of the Sheffield Chamber of Commerce, the secretary reported that a subscriber of the Chamber had made complaint that, notwithstanding the recent declaration by the Treasury that any user of the trunk wire, if he found that the three minutes allowed were not sufficient, was entitled to have another three minutes' consecutive to the first on payment of a double fee, he had been refused the second period. The Secretary said he had brought the circumstances under the notice of the Treasury, who had promised to make enquiry into the matter. The secretary was directed by the Chamber to call to the attention of the commercial community of the district, through the Press, that any trader using the trunk telephone wire is entitled to, and should insist on, if necessary, a second period of three minutes being allowed him on payment of a second fee, thus allowing a conversation of six minutes. But why should not the Post Office get the officials informed of the rules? It is not much good "insisting" through a telephone wire.

Not the Way.—At Bury St. Edmunds they have been discussing the economics of the incandescent electric lamp with the aid of a band and banners, a procession, irrelevant speeches, and all the ordinary paraphernalia of a political "demonstration." This is a method which, though greatly favoured for the treatment of complicated questions of statecraft and sociology, has not hitherto been considered applicable to the comparatively simple problems of engineering and accounts. In the scheme proposed for adoption at Bury St. Edmunds there are points as to which any ratepayer who happened to possess a knowledge of the subject might reasonably require further information before he approved it, but if the electric lighting is not to be the town's affair, but the committee's own private speculation, what was there to "demonstrate" about? The curious condition of things will come in the future when the Town Council tries to discuss any question of public lighting. With the aldermen and councillors on the left of the table disfranchised because they hold gas shares, and those on the right voiceless because of their connection with the electric lighting syndicate, it would be rather distressing if the miserable remnant that belonged to neither side were either to develop ideas of its own or to show its impartiality by voting for oil or candles. But, seriously, it will demand considerable courage on the part of that remnant to decide between the rival interests.

Newcastle Science College.—We have received a copy of the calendar of the Durham College of Science, Newcastle-on-Tyne, for the session 1896-7, and a prospectus of both the evening and day classes. A portion of the work done there which may be specially noticed is that of the evening classes organised to meet the wants of the rising generation of artisans. The instruction is practically free, as will be seen from the following clause: "Apprentices and workmen will be admitted to the classes in elementary mathematics, technical electricity, steam boilers, and chemistry of fuel, iron, and steel at a fee of 2s. 6d. for each course, which fee will be returned if they attend to the satisfaction of the lecturers and apply for its repayment before June 24.' Special courses of lectures will be delivered on telegraphy and telephony by D. H. Kennedy, while the general department of physics is under the control of Prof. H. Stroud, M.A. We also notice a course of lectures on the "Principles of the Law of Contract," by Mr. H. S. Mundahl, B.A., LL.B., which should be of great interest to the rising business man. Evening students can now matriculate at the college and obtain the different degrees. The prospectus of the day classes shows what a large range of subjects are taught at the college. The new course commences on September 28, on which day the matriculation examination for new students will be held. We note that several scholarships will then be open for competition.

Dissociation and Electrolysis.—An abstract of a paper on electrolytic dissociation and light absorption which was contributed by Mr. F. G. Donnan to the *Zeitschrift für Physikalischen Chemie* has been given in the *Journal* of the Chemical Society. Mr. Donnan has investigated the light absorption of solutions of violuric acid by aid of a colorimeter, of which diagrams and a description are given. The dissociation in N/32, N/64, N/128, and N/256 solutions are calculated from the absorption, and the results are found to agree well with those obtained from the conductivity. The addition of hydrogen chloride causes a decrease in the dissociation, and the concordance of the colorimetric and conductivity results is again satisfactory. Parahydroxybenzoic acid was also employed instead of hydrogen chloride owing to the approximate equality of its dissociation constant to that of violuric acid, and in this case, as also for the addition of levulinic and acetic acids, satisfactory results for the decrease in dissociation were obtained calorimetrically. The addition of sodium chloride gives rise to an indeterminable equation for the concentration of the colouring ions; but, on the assumption that the undissociated sodium violurate possesses an absorptive power equal to that of the acid ion, an approximate result is obtained which is, however, not in good agreement with the colorimetric observations. The assumption is afterwards shown to be not quite correct, as the absorptive power of the salt is slightly greater than that of the acid ion.

The Locomotives on Highways Bill.—We give in another column the text of this Act, which has now become law, and which is also the cause of a jubilant letter in our correspondence column. We learn from the latter that the president of the Self-Propelled Traffic Association is mainly responsible for the concession embodied in the Act. There is no doubt that the legislation of the country has hindered the development of self-propelled vehicles, and it is to be trusted that a practical advance in the matter will now be made. It is useless to go into raptures, as has been the custom of the non-technical Press of late, over every vehicle that runs alone. What is wanted is rather a cheaper means of transport on the ordinary roads than is afforded by horse traffic. The matter may be taken up by gentlemen who, to quote our correspondent's letter, are "entirely disinterested and unbiassed by personal or pecuniary motives," but it is the personal and pecuniary advantages to the users that are wanted to make the movement a success. Up to the present the chief development has been that of selling or trying to sell doubtful patents to the public. A really valuable patent would probably come first under the consideration of men of business, who would not care to divide profits with the public, if in any way they could avoid it. At any rate, the passing of the Act

Digitized by Google

is to be commended, and those gentlemen who have assisted the Self-Propelled Association in obtaining the Act are to be congratulated. It is to be hoped that the power vested in the Local Government Board to frame regulations will not be used in such a manner as to vitiate any of the concessions intended to be granted to those who desire to use self-propelled vehicles on the ordinary roads.

The Dynamic Forces in Iron-clad Armatures.—We have already referred to this subject in a note on some theories or opinions of Mr. T. Wolcott, and complained that no facts were given. A more practical contribution to the knowledge of the subject has recently appeared in the *Electrical World* in the form of a record of some experiments by Messrs. Houston and Kennelly. The article is reprinted in this issue, and will repay careful reading. An examination of the results is made somewhat difficult by a lack of detail as to the dimensions of the apparatus used, but the conclusions are practical, and as far as they go are satisfactory in showing how little real knowledge of the subject at present exists. In the starting position the experimenters find that practically all the torque is exerted on the iron of the armature, and only some 1·6 per cent. on the copper conductors. This latter fact is what our theories lead us to expect, as in the stationary condition practically no induction passes through the copper wire. The question still requiring attention, in our opinion, is the very important one as to whether when running these conditions alter, or, in other words, is the static pull on the iron core of a toothed armature any greater than that on the wires of a smooth core with the same M.M.F. and air-gap. An easy way of testing this roughly would be to compare the static and running torque of a toothed armature under the same conditions as to armature current and field strength. The experiments also bring out the fact that the motion of the conductors in the slot does not generate E.M.F. But when the whole core is moved there is an E.M.F. generated corresponding to a cutting or threading of lines of force, and it may be suggested that experiments are still wanting to prove that a force is not then exerted on the copper.

Incandescent Lamp Ring.—It is stated by the *Western Electrician* of America that the various lamp manufacturers have decided on a fixed price for all lamps sold in the States. The tariff is to vary with the candle power—as follows:

Candle-power of lamp.	Price per lamp for small quantities.	Price per lamp in standard packages.
8 to 25	11d.	10d.
32	1s. 5½d.	1s. 3d.
50	2s. 3½d.	2s. 1d.
100	4s. 7d.	4s. 2d.
150	6s. 10½d.	6s. 3d.

These prices are for lamps with Edison and Westinghouse sockets. In lamps with Thomson-Houston, United States, Brush-Swan, or Schaeffer sockets, ½d. more per lamp must be charged. With Hawkeye sockets 1d. more, and for any other kind 1½d. more. The sizes of the standard packages are defined as containing numbers of lamps as follows: for 8-c.p. to 25-c.p. lamps, 200 lamps; 32-c.p. or 50-c.p. lamps, 100 lamps; 100-c.p. or 150-c.p. lamps, 20 lamps. These figures are said to be unofficial, but the journal in question considers that they have sufficiently good authority to warrant publication. The penalties fixed for infringement of the rates are heavy, and should keep the various firms in line as regards price. The competition thus will be only on the ground of reliability and efficiency. On the whole, the public are likely to gain by the uniformity of price if no further increase is decided on. With incandescent lamps the cost of manufacture per lamp sold is largely a matter of selection of the best and of destroying a certain number of imperfect lamps. Hence makers of no repute can net a large profit in a short time by selling the bad lamps with the good ones at a low price. Such a practice should be stopped by the uniform rate.

Helium and Argon.—It is reported that Prof. W. Ramsay and Mr. J. Norman Collie have by fractional diffusion through porous tubes separated argon into two portions, of which the lighter has a density of 19·93, and the heavier of 20·01. Similar experiments with helium gave densities of 1·874 and 2·133 for the two extreme portions, results which were confirmed by measurements of the refractive indices by Lord Rayleigh. The result is interesting, though not unexpected. Considering, however, that by the method employed not even an approximation to purity is obtainable there does not seem much justification for an eminent scientific contemporary outraging dynamics with the remark that since apparently identical spectra are obtained from both the heavier and lighter portions of the gases, "the possibility is suggested of there being here a true separation of light molecules from heavy molecules of the same substance." In spite of its characteristic spectrum the spectroscopists absolutely failed to discover the argon they were breathing every day until the chemists separated it and gave it them in a tube, while as to helium, though they named, numbered, and wrote magazine articles about it, they were quite unable to find any of it nearer than ninety million miles from South Kensington. Under the circumstances one would have expected the exponents of spectroscopic methods of research to have kept very quiet for a time. With regard to argon, providing it has a two-atom molecule, it may reasonably be expected to consist of three gases of nearly the same weight and very similar properties, and of which two would be much less common than the third. Hence the difficulty of separating them. The same may be true of helium, but the inference, which is at best only an empirical one, is less strong. If the molecule is really monatomic, one of the two constituents ought to have nearly double the atomic weight of the other. Finally, it may be said that from researches by Mr. Siegfried Friedländer, published in the *Zeitschrift für Physikalischen Chemie*, it appears that there is a minute proportion—perhaps, a thousand-millionth—of helium present in air, and that under prolonged electric action both argon and helium are at any rate absorbed by platinum, if they do not really combine with it.

Mechanical Stokers.—The New York *Electrical World* believes that the many recognised advantages possessed by the automatic mechanical stoker over the ordinary methods of hand firing have failed to make its adoption more general principally for the reason of its high first cost, cost of repairs, and the necessary attendance required for its successful operation. In a paper read before the St. Louis meeting of the American Society of Mechanical Engineers, Mr. Whitham has given the results of numerous tests on three typical types of mechanical stokers with rocking and chain grates and adapted to the use of the cheapest grades of anthracite and bituminous coals. Mr. Whitham points out that a saving of 40 per cent. can be effected in plants of 500 h.p. using mechanical stokers and provided with coal-handling machinery. Although such stokers do not develop a capacity equal to the hand-firing methods, they are more constant in the power developed and readily respond to large fluctuations in load. They may be characterised as being always in the condition of a hand fire immediately after cleaning. Such working naturally tends to a longer life of the boilers. By employing mechanical stokers the

Digitized by Google

poorest grade of coal may be used without smoking, and at the same time with economical combustion. They, however, require power for their operation, which may be either an electric motor or small steam-engine. Moreover, practically all stokers require a strong draught, either natural, induced, or forced, and this adds another item of cost to that of operating. If a steam plant be used, this will require from 5 to 11 per cent. of the total amount generated, whereas a fan blast requires from 3 to 5 per cent. A steam blast, when used as an aid to combustion, produces an exceedingly long flame, which results in obtaining a more uniform heating surface, and causes a more uniform expansion throughout the boiler than can be obtained by short flames, having a more or less local application. Clinkers are at the same time avoided, and the grates have a longer life. When the demand upon the boiler is not severe, it has been found preferable to shut off the steam blast when such is employed; but care must be exercised to prevent undue heating of the grate. In stations requiring a graduated air blast, still greater care is necessary to regulate the amount of air admitted.

Li at Greenwich and Elsewhere.—Last Friday morning His Excellency Li Hung-Chang went to the Telegraph Construction and Maintenance Company's Works at Greenwich, as per programme. The usual order was reversed, and the telegraphing was done before luncheon instead of after it, so that the Chinese end had not to stay late for the messages after all. Li, however, did not get on to Pekin, the Chinese Internal Telegraph Administration apparently not being propitious, but the Eastern Extension Telegraph Company, in conjunction with the Great Northern Telegraph Company, put him on to Shanghai and Tien-tsin. Transmission to Madras was done in two and a half minutes, which is a record for the Eastern Telegraph Company. It took 10 minutes longer to transmit to Shanghai. His Excellency seemed mainly anxious to know the precise whereabouts of a certain Lord Shen. It is noteworthy that in the replies from China Li was given his proper style, which is not usually done here. Also he was not troubled with the difference between English and Chinese time. He is an extraordinary man, and doubtless when he goes back will find out that his messages were received in the evening. Meanwhile, various stations along the route telegraphed their weather. It was fine at Malta (it always is) but damp at Alexandria, which is not in accordance with the fitness of things. However, as Li Hung-Chang is not going back that way he probably did not care. During the week he has gone north and has been saying complimentary things about steam, electricity, and English philosophy. He got rather mixed in his list of English philosophers, but that is excusable. Other people have done the same before, and some Germans have gone so far as to say there are none. But on science and engineering he was very strong. English science, he says, is too exclusively practical, and Chinese too abstract, but it only requires that they should be brought into conjunction, and the greatest results may be expected. If His Excellency wants to see what we can do in the way of keeping down practicience (this is according to rule) and cultivating abstractivity he might consult some of our mathematical writers on electrical theory. He knows English, though he chooses to talk with an interpreter—that discovery was made at Greenwich—and a man who has asked a lady her age, a journalist his salary, and a director the amount of his holding of ordinaries, all in one week would obviously not be afraid to tackle anything.

Contact Resistance.—Mr. Charles West has made an interesting contribution on the subject of contact resistance to our New York namesake, the *Electrical Engineer*. He emphasises the great difference in the contact resistance between surfaces at rest and in motion, and refers to some experiments carried out by himself in the Edison Laboratory. In this instance, the experiments were conducted on surfaces at rest, and the following were the conclusions arrived at: with pressures between 25lb. and 250lb. per square inch resistance varies nearly inversely as the pressure; the total pressure remaining constant, reduction of area does not alter resistance within wide limits; pressure and area remaining constant, variations in the perfection of fit between the surfaces produces slight, if any, change in the resistance; clean petroleum oil placed between the contact surfaces does not greatly alter the resistance; clean petroleum oil mixed with pure graphite to the consistancy of cream does not greatly alter the resistance; a washer of thick tinfoil (pure tin) interposed between the contact surfaces gave a total resistance for the double contact not greater than the single contact of the blocks with each other, except with the lighter pressures. No time tests were made. During the experiment the two surfaces were fitted until the lower block could be lifted by the upper block by suction. Ordinary care was taken to exclude dust. The slight effect of oil on the resistance is surprising, as with well-fitted surfaces and only moderate pressure it might be expected that a continuous film of oil would interpose between the plates. It would appear that actual contact between the surfaces with moderate pressure, even with well-fitted surfaces, is at a few points only; that increase of pressure brings more points into contact in proportion to the pressure; also that the actual points of contact are able to displace the liquid film. The author concludes that large surface of contact is of value, in switches for instance, for giving increased radiating surface and proper conductivity without undue pressure per unit of surface area—that is to say, in switches while conductivity might be secured with less surface than is now the usual practice, under sliding motion such pressure would give increased tendency to cut. In 'bus-bar joints, and similar cases of joints carrying large currents, where the conductors are ample, if a heavy pressure can be secured and maintained, the area of contact may safely be reduced to the amount required by mechanical considerations. It is also probably true that in such joints the interposition of a washer of pure tin, not too thick, is of advantage in protecting joints from the effects of corrosion.

Electricity in the Coal-Mine.—At the meeting of students connected with the Federated Institution of Mining Engineers, at Leeds, the principal business was the discussion of a paper by Mr. Roslyn Holiday on "The Application of Electricity to Mining Operations." Mr. Holiday, in the course of his paper, stated that in mining operations there were hardly any uses to which power was transmitted by hydraulic, pneumatic, or mechanical agency to which electricity could not be applied. The principal question, however, was whether it could be applied more economically than other forces, and without endangering the lives of the men. Whether it was economical to use electricity depended to a large extent on local circumstances. Among the advantages of electricity were its adaptability to a variety of purposes and its portability. The first use to which mining engineers applied electricity was in the pumping of water, and though that was not the kind of work in which it showed to the best advantage (except in the case of dip pumps), still, the advantage of having a pair of cables and a column of pipes fixed in the shaft instead of a lot of moving spear-rods was evident. As regards the underground haulage, it would be hard to find anything to beat in economy an engine on the surface driving a rope which was carried down the shaft,

Digitized by Google

In the driving of underground fans electricity could be advantageously applied. The great drawback to the use of electricity in mines, especially at the working face, was the liability to "sparking." No continuous-current motor had been made which had not a commutator, and to render those machines safe the expedient of completely boxing them in had been resorted to. There was, however, the alternating motor of the polyphase type, in which there were no commutator. That machine, if electricity was to be used at the coal face for cutting and drilling, was, in the writer's opinion, the most suitable one. A combination of dynamo and motor should not involve a loss of more than 10 to 15 per cent. of the total power delivered to them. The Chairman (Mr. G. A. Mitchell) remarked that the first cost of motors was greater than that of steam-engines and pipes. Mr. F. E. Parrington, Wearmouth Colliery, Sunderland, said there was a disadvantage in alternating motors, as they pulled up when very slightly overloaded. Mr. Bell, also of Wearmouth Colliery, said that in the Durham and Newcastle coalfields there were not three collieries where electricity was used as a motive power. If sparking occurred in the return airway the results would be disastrous. There is always a disposition to stand in old ways, but if sparking is the only difficulty in the way of electric working in the coal mine, that can be got over without waiting for the coming of the commutatorless continuous-current motor. It has been looked for in America, but it is considered wiser not to go hunting a will-o'-the-wisp.

Electric Dredger.—Some time ago we briefly noted the construction of an electrically-driven dredger for Mr. P. Bunau-Varilla, who designed to use it for the purpose of fetching up ballast from the bed of the River Esla for the new railway between Plasencia and Astorga. This dredger and its work has formed the subject of a descriptive article by Mr. Felix Boix in the *Revista de Obras Publicas*, and an excellent process print is given of a photograph showing the dredger at work. The article is much too long for reproduction in these columns, but some additional particulars beyond those we have been able to give before may be noted. The generating station contains a 150-h.p. horizontal com pound engine, which can be run either with or without condensing. Steam is supplied by a cylindrical boiler with copper tubes. The generator is a belt-driven triphase machine, giving current at 2,000 volts (alternating). There is a switchboard and the usual accessories, and the current then goes to the dredger by an overhead line with bare copper wires for the land portion and a highly insulated cable through the water. The dredger is a bucket one of an exceptionally substantial type, and is constructed of iron and mild steel. On reaching the dredger the current is transformed down to 200 volts and distributed to the various motors, These consist of a 45-h.p. Brown motor running at 600 revolutions a minute and used to work the bucket drum, and another 10-h.p. motor of the same speed, which works a centrifugal for washing the ballast as it comes from the buckets. Besides these, in the after part of the dredger, there are two 25-h.p. motors working screw propellers. The dredger will work to a depth of about 23ft. The buckets are steel lipped, and the inclination and, consequently, the depth of dredging, is determined by a cable winding on a drum. This latter is worked by a 15-h.p. motor, which for a charge is run at 800 revolutions, all the other motors going at 600. The method of gearing down is not stated, probably in this case it would be a worm gear. In this respect details are wanting as to all the motors. The dredger is expected to excavate about 144 cubic meters per hour, or more than 1,500 loads of ballast for a 10-hour day. Various advantages are claimed for an electrically-driven dredger over one of the ordinary steam type, but of these the most important appears to be the removal of the weight of the steam-engines, boilers, and coal stock from the dredger to the central station. As for excavation work by means of a floating dredger a fleet draught for the latter is of the essence of the business, the importance of removing all unnecessary weight is evident. Finally it remains to be said that the dredger was constructed by A. F. Smulders, of Rotterdam, from the designs of Mr. Bunau-Varilla; the electric work was done by Brown, Boveri, and Co., of Baden (Switzerland). The dredger was put together and tried on the Maas in the presence of the principal engineers of the Dutch Waterstaat, and worked well. How she has been got out to Spain across the Bay is not known to us.

Rontgen Rays in Surgery.—Dr. H. Lewkowitsch has an article in last week's *Lancet* on a new method for the application of Röntgen rays in ophthalmic surgery with the view of detecting the presence of foreign bodies in the eye and determining their position. Ordinary light and the ophthalmoscope give no help when the foreign body is very small, or when it is embedded in the non-transparent tissues of the eyeball, or where a large extravasation of blood obstructs the view of the fundus of the eye, and where the cornea has become impermeable to light; and the magnet is useless for anything but iron. For such a case as finding the position of a small piece of glass, Dr. Lewkowitsch considers the Röntgen rays method applicable, and he has experimented on dead eyes and (so far as possible) on himself. There is no need to go into surgical details, but the main difficulty is, of course, that the eye is surrounded by a bony case. The difficulty is got over by a special form of plate capable of being "inserted into the orbital cavity between the os lacrymale and the eyeball." Of course, this is done under cocaine anæsthesia. Mr. R. Barwell contributes an article to the same journal on the use of the Röntgen rays in determining the proper treatment in the case of congenital deformity of the feet. While on this subject it may be mentioned that at the meeting of the British Medical Association at Carlisle Dr. J. Macintyre gave a demonstration of the means by which he had obtained results in his attempts to photograph and see on screens the deeper-seated structures of the body. He first pointed out that in photographing the lower animals he had got fairly satisfactory shadows of certain organs within the cavities. Proceeding to make a series of experiments he had found, contrary to expectation, that greater currents were required. One might have thought that if photographs of the bones were to be got with certain apparatus in a given time then by diminishing the exposures it might be possible to catch the soft tissues before they disappeared. This proved not altogether true. In the centres, particularly the heart, the tissues were dense, and for these it was necessary to use large currents. He could photograph the spine and omit the heart and sternum, and, on the other hand, the latter could be got and the spine omitted. The limits of the pleural cavities, the heart in movement, the diaphragm in action, enlargement of the heart, liver, etc., had all been seen. A case of renal calculus photographed and since successfully operated upon was described. At Munich, where, as we noted last week, a good deal of fuss was made over some similar experiments, they appear to have since gone on to talk nonsense about "cosmical vital force." Those sort of things will happen at an international congress of psychology, but it is disappointing all the same, because it was from Munich that the first results came of attempts to measure wave-lengths beyond the ultra-violet.

THE 1896 MEETING OF THE VERBAND DEUTSCHER ELEKTROTECHNIKER IN BERLIN.

(BY OUR SPECIAL CORRESPONDENT.)

(Continued from page 120.)

Interview with Mr. H. Gorges.

I was introduced to the above-named gentleman after the Saturday's meeting of the Verband. He had then just been reading his paper on the methods of varying the speed of rotating field motors. His name has appeared at the head of so many important additions to the knowledge of theory and practice of alternating-current apparatus that his opinions are valued most highly. Mr. Görges kindly promised to grant me an interview and to show me the works of his firm, Messrs. Siemens and Halske. I gladly availed myself of this promise early in the following week. At the works I had a struggle with the *portier*, to whom I at last managed to explain in German what my business was. He then used the telephone and mutilated my name to somewhat the same extent that I had previously injured his native tongue. Mr. Görges kindly sent one of his staff to conduct me to his office, which is situated some distance from the general offices of the firm. On the occasion of the Verband visiting the Berlin Exhibition, as mentioned elsewhere, we were allowed to travel gratis on the electric line equipped by Messrs. Siemens and Halske to carry the public from the heart of Berlin to the exhibition. I was then much impressed with the power of the motorcars, which had two trailing cars attached. In answer to my queries, Mr. Görges informed me that the overhead part of the line from Lindenstrasse to the exhibition was about 4½ miles long, and at the city end there is about another mile of conduit work. The same cars run the full length of the track, the collecting gear only being altered to suit the system of supply. The speed of the cars varies considerably with the nature of the street, but after leaving Berlin there are several long runs over which an average speed of 12 miles an hour is maintained. My impression is that the maximum speed is something over 20 miles an hour. There are two motors on the front cars, each of 12 h.p. nominal, but this power is reckoned at the speed of eight miles per hour, and not by multiplying the starting torque into the maximum speed, as is too often done. The lines have been equipped under a two years' concession, but it is likely that the public will object at the end of the time to having the track pulled up and their convenient means of travelling removed. The motorcar and two trailers are capable of carrying some 100 passengers without crowding.

We then left the subject of electric traction for that of alternate currents and the polyphase systems. Siemens and Halske find that of their annual output of electric generators and motors, about two-fifths of the total power is for work on the polyphase systems. The three-phase system is almost always used in preference to the two-phase on account of the advantages the three-phase motors have over their duplex rivals. The latter system has, however, some advantage, in Mr. Görges's opinion, where many lamps have to be supplied, as individual groups do not affect the whole. Still, with well-designed three-phase generators there need be no trouble. The great aim in the design in such cases is that the reaction in the armature of the generator shall be small. Thus, in Chemnitz, Messrs. Siemens and Halske have installed a complete three-phase system with transformers, and a difference of more than two volts between the different phases is not found under any ordinary conditions. Messrs. Siemens and Halske have also recently designed a 1,000-h.p. plant for transmission of power in Guatemala with similar conditions. The voltage adopted in this case was 10,000, and the power will be employed for lighting and driving small motors.

If the tramways care to take the supply rotary transformers will be used. I found that Mr. Görges supported the practice of using synchronous motors, as is done on the Dublin-Dalkey line.* He thinks that the advantage of having a power factor of unity, and saving some 10 to 15 per cent. in the current transmitted in the high-tension feeders, for a given power warrants the adoption of the synchronous motor rather than its lagging *confrère*. Still, in some cases where the starting devices cannot be conveniently applied, he has used the non-synchronous motor for the above purpose.

I then asked Mr. Görges's opinion of a statement made to me before leaving for Germany that no Continental maker could make a single-phase motor to start under full-load torque. He assured me that his firm manufactured a large number of such single-phase motors which will start under full-load torque and only take 2½ times the full-load current. If, on the other hand, the current is kept down by suitable arrangements to the normal full-load value, the starting torque is about half that at full load. The starting gear used consists of a combination of resistance and induction coils. The efficiency of these single-phase motors is not so high as with the polyphase ones, ranging from 6 to 10 per cent. less. Thus the efficiency of the polyphase motor manufactured to Mr. Görges's designs varies from 80 to 85 per cent., according to the size of the motor. The single-phase motors have, on the other hand, efficiencies from 70 to 78 per cent. All these figures are for a frequency of 50 complete periods per second, which is the standard frequency throughout Germany. This frequency has been found to be the best for general purposes, but for transmission work only Mr. Görges prefers a lower periodicity. He stated that a rise of frequency considerably increases the leakage drop of a transformer. The reason of this at first is not obvious, as with the lower frequency a higher induction is used. This higher induction means a higher value for the magnetic potential, which will give a slight increase in the leakage from the iron. This leakage from the iron is not, however, the chief cause of the magnetic drop. Mr. Görges explained that the leakage is due rather to the induction in the space between the two sets of coils. (The core type of transformer made by Messrs. Siemens and Halske is not unlike that manufactured by Messrs. Johnson and Phillips, in England, and has the primary and secondary coils wound on concentric cylinders.) In this space the magnetising force is thus produced by the sum of the ampere-turns in the primary and secondary coils, and hence the induction reaches an appreciable value, although the medium is air. Now, if a high frequency is used, the induction in the iron is lowered, and the proportion between these leakage lines and the lines through the iron therefore is increased. This increases the drop appreciably. The effect is magnified if the transformer is used for high voltages, which necessitates a large air-gap between the primary and secondary windings. For this and other reasons, Mr. Görges prefers a frequency of 30 ∿ for transmission work only. We then agreed to disagree over the question of the effect on a motor of this reduction in frequency. Mr. Görges stated his case thus: With the lower frequency you can get more output for a given weight, because you can use a larger induction in the iron. Also you save copper. I submitted that if the output of the motor was limited by its rise in temperature, you reduce the output by lowering the frequency because the hysteresis loss is increased. On the other supposition, that the output is limited by the armature reaction causing a drop in voltage, the lowered frequency will again lower the output. We agreed, finally, that the lower frequency gave more mechanical designs for ordinary speeds of the motor, and also a larger proportion of iron per total weight.

Mr. Görges then kindly showed me over the works, and we were thus able to examine several of the machines we had been conversing about. I was especially interested in the core-stamping department. The accuracy of the armature plates turned out from this department is wonderful. The number of automatic and self-feeding punching machines enable the work to be turned out economically. The plates, when put together to form armatures or field-magnet systems, present a surface which looks as though it had been machined.

The starting device much used in these works for reducing the starting current of polyphase motors is shown diagrammatically in the adjoining Figs. 1 and 2. The

* *Electrical Engineer*, vol. xvii., page 537.

Digitized by Google

armature is provided with two circuits for each limb of the three-phase system. These two circuits are different both as to the number of turns and resistances. In starting, as in Fig. 1, the E.M.F.'s induced in each circuit of each limb oppose each other and the acting E.M.F. is the difference between that in each of the two circuits. The current is,

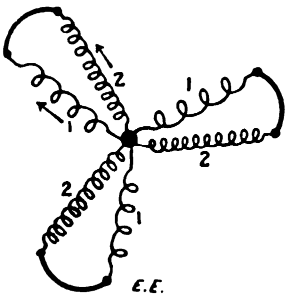

FIG. 1.—Starting Connections for Armature of Siemens and Halske's Three-Phase Motor.

of course, also proportional to the resultant E.M.F. When the ends of each limb are permanently connected together, as is the case when running (Fig. 2), each circuit can act independently, and the effect is therefore increased nine times if the ratio of the turns in each of the parallel circuits is 2 to 1. The short-circuiting of the ends is easily effected

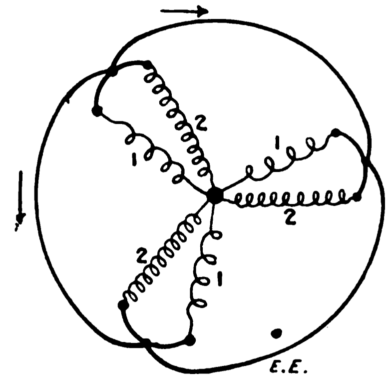

FIG. 2.—Running Connections for same Motor.

by a lever at one end of the motor working on an attachment similar to that used in the steam-engine governor.

The method used in the works of measuring the power given to three-phase motors is that due to Prof. Frölich. The connections used are shown in Fig. 3. The apparatus consists practically of three coupled Siemens dynamo-

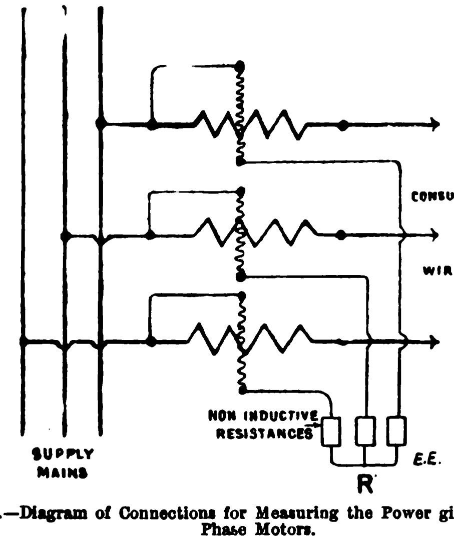

FIG. 3.—Diagram of Connections for Measuring the Power given to Three-Phase Motors.

meters. The three thick wire coils are placed in series with the wires supplying the motors, and the thin wire coils are connected through non-inductive resistances to a common terminal. The instrument so connected gives the total power delivered to the motor, and is independent of any variation in either circuit.

(To be continued.)

RAILWAY BLOCK SIGNALLING.

BY J. PIGG.

(Continued from page 149.)

WALKER'S BLOCK INSTRUMENT.

The external appearance of this instrument is shown by Fig. 3. The connections for a block section are shown by Fig. 42, and further details of the mechanism are given by Fig. 42A. Details of the construction of the signalling key are given by Fig. 43. The upper electromagnets work the white arm, and the lower work the red arm and bell. The current passes through the upper coils at the home station, and through the lower coils at the distant station. The signalman at any station, therefore, works the white arm at his own station, and the red arm and bell at the distant station simultaneously. The signalling key is simply a current reverser. The upper, or white, knob sends a current through the upper coils

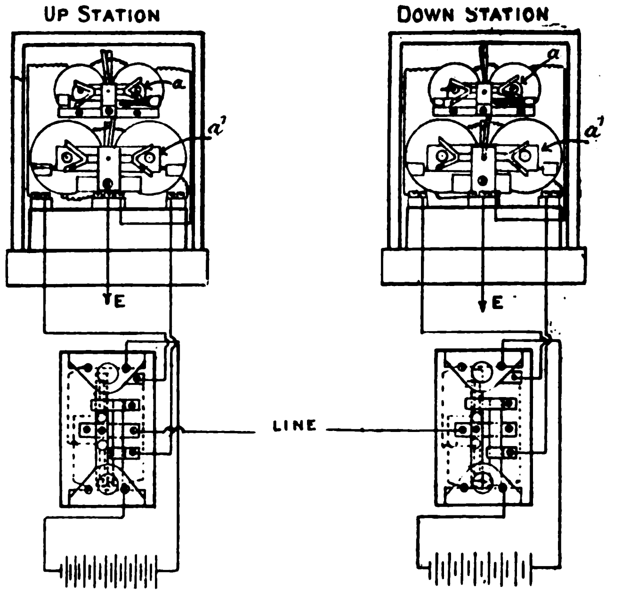

FIG. 42.—Double-Line Block Circuit—Walker's Instruments.

at the home station, earth, lower coils at the distant station, line, to zinc at the home station. The result is to raise the white arm and red arm at the home and distant stations respectively, and the bell at the latter place is also rung. The lower or black knob reverses the direction of the current and lowers the arms at the two stations and also rings the bell at the distant station. Both sets of electromagnets actuate polarised and non-polarised arma-

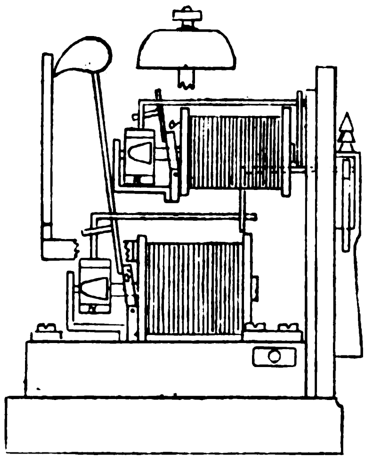

FIG. 42A.

tures. The V-shaped permanent magnets actuate the arms when a current passes in the proper direction. The non-polarised armature, *a*, of the upper electromagnet locks the polarised armature in position. The non-polarised armature, *a'*, of the lower electromagnets carries the bell hammer, and also locks the polarised armature in position.

It will be noticed that descriptive signals must be given by a bell code; and, also, since the bell is rung by the

Digitized by Google

depression of either of the two knobs of the signalling key, either would serve for sending train-distinguishing signals by bell code if there were no other considerations to take into account. The particular knob to be used at any time, however, depends entirely on the indications exhibited by the instruments. Thus, suppose a train to be in the section on the "down" line and a train is to be signalled on the "up" line. The signalman at the sending end for the "up" line must give any bell signals on the white knob, or he will lower the arms, representing the condition of the "down" line. On the other hand, the signalman at the receiving end for the "up" line must acknowledge bell signals on the black knob, or he will raise the arms representing the "up" line prematurely. If there are no trains in the section, bell signals are given and acknowledged on the black knob. The position of the arms is horizontal when trains are in the section; when no trains are passing the arms are lowered. There is, therefore, no indication corresponding to "Line clear" or section ready for train to enter with this form of instrument.

Preece's Block Instruments.

Another form of block instrument for use with transient currents and one line wire is shown by Fig. 44, which represents, diagrammatically, the connections for a block circuit using Preece's block instrument. In this form of instrument the indicator for approaching trains is of a different form to that for receding trains, in addition to being in a different position on the face of the instrument. The "on" "off" disc at the upper part of the instrument is the indicator for trains passing *from* that station; the semaphore arm is the indicator for trains *approaching* that station. The disc indicator at the sending station is practically a repeater for the semaphore arm at the distant station, in that its movement shows that the actions of the signalman at the distant station have been such as are calculated to lower the semaphore arm at that place. The position of the disc is "on" and the corresponding position of the semaphore indicator is horizontal, both when trains are actually passing through the section and when it is clear of trains, but the difference between these conditions is indicated, where a three-position switch is used, by the switch handle being placed in the position marked "Train on line." There are thus, practically, three different indicators in this form of instrument. Diagram Fig. 44 is drawn to show "Line clear" for a train ready to proceed from the "up" station to the "down" station. The handle of the switch, C, occupies the "off" position shown at the "down" station during the time the "Line clear" signal is being exhibited only.

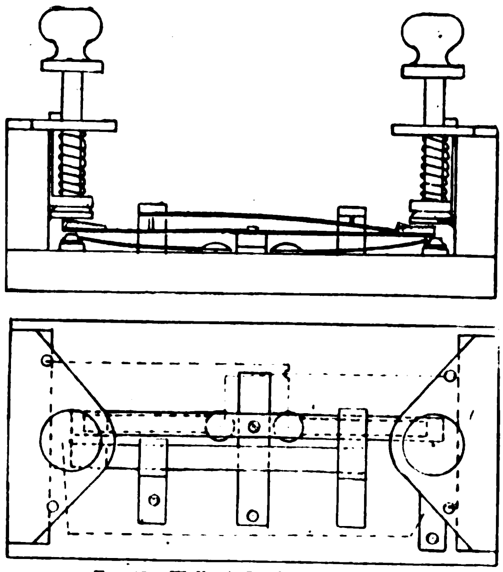

Fig. 43.—Walker's Double-Current Key.

The construction of the instrument presents several points of interest in the methods adopted to ensure efficiency. The disc indicator is actuated by the polarised armature of M_1, and the bell is worked by a non-polarised armature on the same electromagnet. The position of the disc depends, therefore, on the direction of the last current passed through M_1, whilst the bell is rung by all currents passing through that electromagnet. The currents passed through M_1 are from the local battery, and their direction depends upon the position of the switch, S, at that place. The semaphore arm is held in a horizontal position by the detent, *l*, attached to the non-polarised armature of M_2, and also by the forked lever, *g*, which rests saddlewise on the bar connected with the polarised armature of M_3. There are thus two electromagnets to actuate before the semaphore arm can be lowered, and these must be acted upon in a prearranged order. In addition to the polarised armature, N, M_3 actuates a non-polarised armature, which completes two local circuits each time a current passes through M_3. One local circuit is through M_4, and serves to magnetise the armature, N, and the cores, S, of M_3, the direction of magnetisation depending upon the position of the switch. The electromagnet M_2 is short-circuited when the polarised armature of M_3 occupies the position shown at the "up" station, and is not, therefore, affected by currents when the switch is in the "on" position. If the switch at the "up" station, say, is put into the "off" position, and the plunger, K, is depressed, a current will pass *viâ* earth, M_3 at "down" station line, short-circuit of M_2 at the "up" station, and the switch lever to zinc. This current operates the two

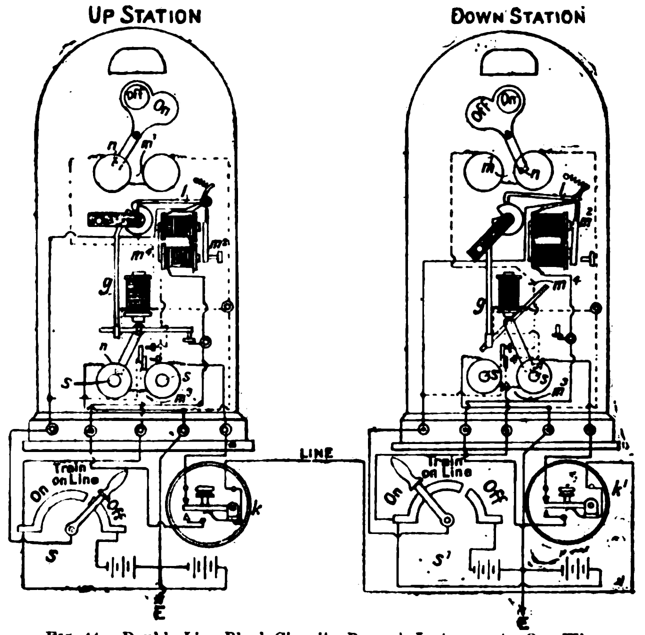

Fig. 44.—Double-Line Block Circuit—Preece's Instruments, One Wire.

local circuits at the "down" station by the non-polarised armature of M_3. One local circuit rings the bell and the other magnetises the polarised armature of M_3, and causes the latter to take up the position shown. The forked lever, *g*, is released, but is still held in position, together with the semaphore arm, by the detent, *l*. The movement of the polarised armature of M_3 to the position shown at the "down" station breaks the short-circuit of M_2. If the plunger, K, at the "down" station is depressed in reply, a current is sent *viâ* M_2 at the "down" station, line, and K, M_3 at the "up" station, and earth to zinc at the "down" station. M_3 at the "up" station closes the local circuits and moves the disc indicator to the "off" position. The instruments are then in the position shown, which indicates "Line clear" for a train to pass from the "up" to the "down" station. When the "Train on line" signal is to be sent, the switch at the sending end is put into the appropriate position and the plunger depressed. The current being in the opposite direction to that for "Line clear," attracts the polarised armature of M_3, and through the forked lever, *g*, raises the semaphore arm, where it is again caught by the detent, *l*. The reply signal to the "Train on line" causes the disc indicator to occupy the "on" position, since the direction of the local current has been altered by placing the switch to "on."

It will be noticed from the diagram that the switches when in the "Train on line" position do not affect

Digitized by Google

the currents sent from the home station in any way different from those produced when the switches are in the "on" position, and the clearing bell signals may be given and acknowledged with the switches in either of these positions. The difference between the "Line closed" and "Train on line" indications are merely shown by the position of the switch lever for the signalman's information. It will be further observed that the obviously most important signal of "Line clear" can only be exhibited by concurrent action on the part of the signalmen at the ends of the section, and unless the actions

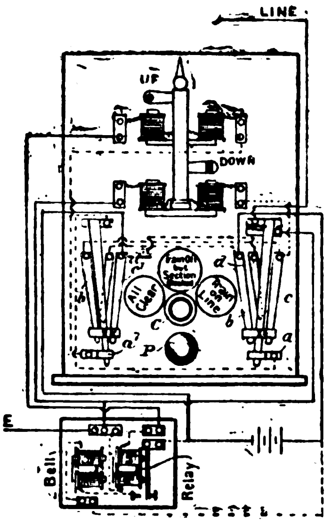

FIG. 45.—Harper's Single Plunger Block.

are carried out in proper sequence no such signal will be exhibited. The semaphore arm at the receiving end is lowered by the direct action of the signalman there, but only after his instrument has been prepared, so to speak, by the action of the signalman at the sending end, and the same action notifies the sending end of what has been done independently of the bell signal. On the other hand, the semaphore arm is raised by the direct action of the signalman at the sending end when the "Train on line" signal is sent.

Harper's Block Instrument.

A further example of a single-wire block instrument is shown by the diagram Fig. 45, which represents Harper's form of instrument. There are in this instrument two different forms of indicator; the lettered discs seen near the bottom of the instrument show what signal has last been *sent* for one line, and the semaphore arms indicate what signal has last been received for the other line. The movement of the discs into their proper position alters the direction of the current through the electromagnets at both stations. These currents are sent by the depression of the plunger at the bottom of the instrument. When the dies "All clear" is being shown, the plunger depresses the long spring on the right hand, breaking contact with *a*, making contact with *d*, and completing the circuit between *b* and *c* by the insulated cross-piece, *h*. The current passes by *b c*, and the lower electromagnet at the home station to earth, the relay, the upper electromagnets, a_1, left-hand spring, *a*, and right-hand spring, at the distant station, line, right-hand long spring, *d*, and zinc at the home station. When the disc indicator is in the position shown, or indicating "Train on line," the left-hand long spring is depressed by the plunger, and the direction of the current is reversed. Since the bell is rung by a local current, the circuit of which is closed by a non-polarised relay, it is obvious that the bell will be rung at the distant station at every depression of the plunger at the home station. Currents passing through these instruments actuate the lower electromagnets at the home station and the upper electromagnets at the distant station, and, since the position of the disc indicator controls the direction of the currents, it follows that the disc indicator at the home station must be set to the appropriate position before the signal can be given. The positions of the semaphore arms are in accordance with the signals *sent* and *received* respectively for the lower and upper semaphores, and by their position represent the character of the indication exhibited by the disc indicator at the distant station, in so far as the difference between the "All clear" and the "Train on line" or "Train blocked" signals is concerned, but do not indicate the difference between the two last-named conditions of the line. Obviously the difference between the "Line blocked" and "Train on line" indications at any one station exercises no influence on the character of the indications at the distant station.

Fletcher's Combined Block.

Fig. 46 is a diagram showing the connections for a double-line block circuit with Fletcher's block instrument. In this form the bell-signalling apparatus is entirely distinct from the indicating apparatus, and three line wires are required. The indicators show "Line clear," "Train on line," and "Line closed" by the different positions of one indicator. The "Line clear" and "Train on line" indications are maintained by continuous currents. "Line closed" is indicated when no current is passing. All currents pass through the lower electromagnet at the home station and the upper electromagnet at the distant station. If the commutator at the "down" station, say, is turned to the left, the springs, *a* and *b*, *c* and *d*, are connected, and a current passes to earth at the home station, through the upper electromagnets at the distant station, the line, the lower electromagnets, and the springs, *d* and *c*, to zinc at the home station. If the commutator is turned to the right the direction of the current is reversed, the springs *a* and *d* being connected, and also the springs *b* and *c*, and the character of the indication exhibited is altered accordingly.

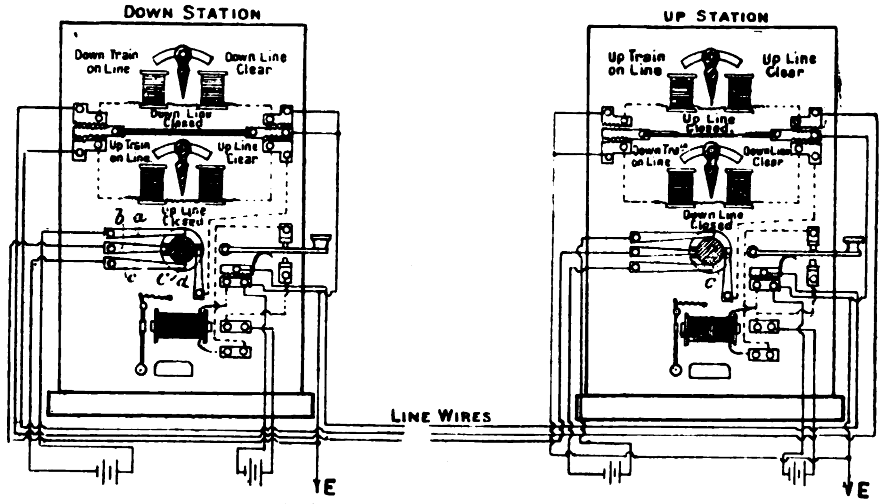

FIG. 46.—Fletcher's Combined Block, Three-Wire. Diagram of Connections for One Section.

Tyer's Semaphore Block Instrument.

The instrument shown in diagram, by Fig. 47, is Tyer's

Digitized by Google

semaphore block. In this form of instrument the signals are sent by the plunger, P, and the direction of the currents is controlled by the position of the commutator, C, which also carries the disc indicators "Line clear" and "Train on line." Currents pass through the lower electromagnets at the home station, and the upper electromagnets

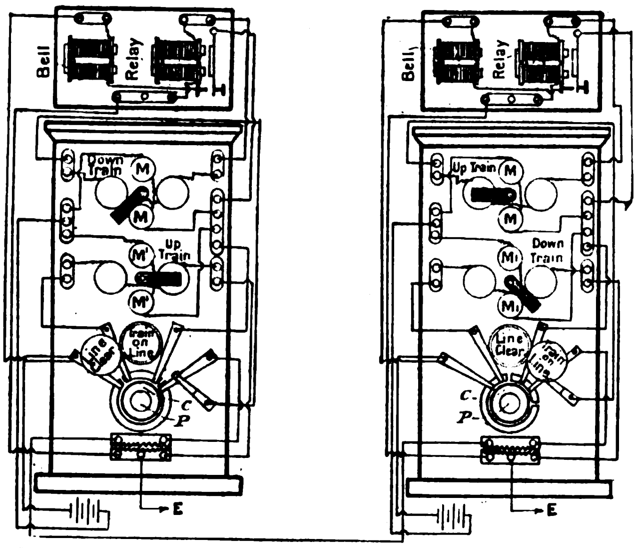

FIG. 47.—Double-Line Block Circuit—Tyer's Semaphore Block Instruments.

at the distant station. The upper magnetising coils, M, are brought into use by the relay: the lower magnetising coils, M_1, are traversed by the currents sent from the home station. As shown in the diagram the instrument makes no distinction between "Train on line" and "Line closed," but in later instruments this distinction is made.

(To be continued.)

THE PRINCIPLES OF ALTERNATE-CURRENT WORKING.*

BY ALFRED HAY, B.SC.(EDIN.), A.I.E.E.

(Continued from page 185.)

45. We shall next consider the distortion of shape produced in a simple harmonic wave by the superposition on it of a third harmonic. The shape of the resultant curve will depend very largely on the phase relation of the two curves. If the two curves are coincident in phase when the fundamental harmonic passes through its zero value, as in Fig. 36, the resultant curve is flattened at the top.

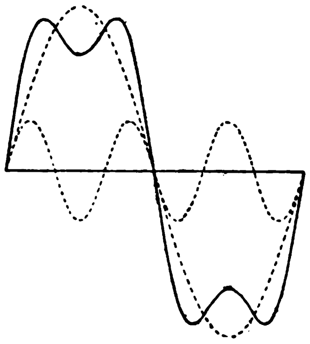

FIG. 36.

If, on the other hand, the two curves are in opposition as regards phase, as in Fig. 37, the resultant curve runs up to a sharp peak. In both cases each half-wave is symmetrical about a vertical line bisecting it. Again, if we take an intermediate phase relation, such as that shown in Fig. 38, there is no longer any symmetry about a vertical axis, and the general shape of the resultant curve is intermediate between those of Figs. 36 and 37, the curve being flattened in one part and peaked in another.

It is found that most alternator E.M.F. curves may be represented, with a considerable degree of accuracy, by the expression

$$e = A_1 \sin pt + B_1 \cos pt + A_3 \sin 3pt + B_3 \cos 3pt + A_5 \sin 5pt + B_5 \cos 5pt. \quad (26)$$

We shall therefore assume that all the curves with which we have to deal may be resolved into the above harmonic terms. The problem, then, of analysing the curve harmonically is reduced to the determination of the

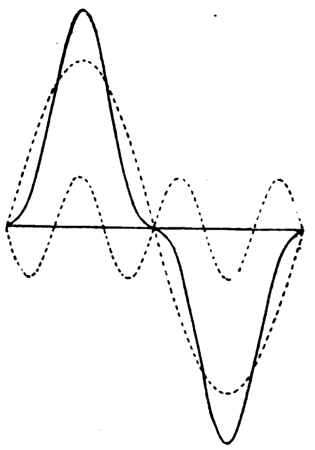

FIG. 37.

coefficients, A_1, B_1, A_3, B_3, A_5 and B_5. This may be effected as follows:

Taking the zero value of the E.M.F. as our starting-point—*i.e.*, as the point at which $t = 0$—let us divide a *half-*

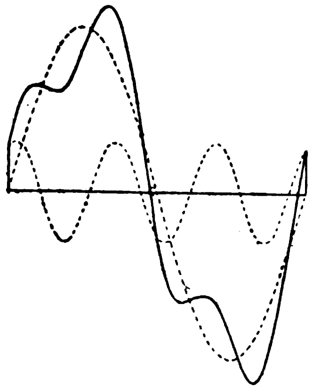

FIG. 38.

period into six equal parts. The values of pt corresponding to the first six points of division, including the starting point, are

$$0, \frac{\pi}{6}, \frac{\pi}{3}, \frac{\pi}{2}, \frac{2\pi}{3}, \frac{5\pi}{6} \text{ radians,}$$

or $$0°, 30°, 60°, 90°, 120°, 150°.$$

From the E.M.F. curve we can read off the corresponding instantaneous values of the E.M.F. Let these be

$$0, e_1, e_2, e_3, e_4, e_5.$$

Then, remembering that $\sin 30° = \frac{1}{2} = \cos 60°$, and $\cos 30° = \frac{\sqrt{3}}{2} = \sin 60°$, we have, by equation (26),

$$B_1 + B_3 + B_5 = 0 \quad . \; . \; . \; . \; . \quad (a)$$

$$\tfrac{1}{2} A_1 + \frac{\sqrt{3}}{2} B_1 + A_3 + \tfrac{1}{2} A_5 - \frac{\sqrt{3}}{2} B_5 = e_1 \; . \; (b)$$

$$\frac{\sqrt{3}}{2} A_1 + \tfrac{1}{2} B_1 - B_3 - \frac{\sqrt{3}}{2} A_5 + \tfrac{1}{2} B_5 = e_2 \; . \; (c)$$

$$A_1 - A_3 + A_5 = e_3 \; . \; . \; . \; . \; . \quad (d)$$

$$\frac{\sqrt{3}}{2} A_1 - \tfrac{1}{2} B_1 + B_3 - \frac{\sqrt{3}}{2} A_5 - \tfrac{1}{2} B_5 = e_4 \; . \; (e)$$

$$\tfrac{1}{2} A_1 - \frac{\sqrt{3}}{2} B_1 + A_3 + \tfrac{1}{2} A_5 + \frac{\sqrt{3}}{2} B_5 = e_5 \; . \; (f)$$

* Based on a series of evening lectures delivered at the University College, Liverpool.

Digitized by Google

We thus obtain six equations, and these enable us to determine the six unknown coefficients A_1, B_1, etc.

Adding (*b*) and (*f*), and (*c*) and (*e*), we get

$$A_1 + 2A_3 + A_5 = e_1 + e_5$$

$$\sqrt{3}\,A_1 - \sqrt{3}\,A_5 = e_2 + e_4$$

Also, by (*d*), $2A_1 - 2A_3 + 2A_5 = 2e_3$.

Adding the first and last of this set of equations, we obtain

$$3A_1 + 3A_5 = e_1 + e_5 + 2e_3,$$

which when divided by $\sqrt{3}$ and added to the second equation above gives

$$2\sqrt{3}\,A_1 = e_2 + e_4 + \frac{1}{\sqrt{3}}(e_1 + 2e_3 + e_5),$$

so that $A_1 = \frac{1}{6}\{e_1 + 2e_3 + e_5 + \sqrt{3}(e_2 + e_4)\}$.

From the other equations, we easily obtain

$$A_5 = \tfrac{1}{6}\{e_1 + 2e_3 + e_5 - \sqrt{3}(e_2 + e_4)\},$$

and $A_3 = \frac{1}{3}(e_1 - e_3 + e_5)$.

Next, subtracting (*f*) from (*b*), and (*e*) from (*c*), we get

$$\sqrt{3}\,B_1 - \sqrt{3}\,B_5 = e_1 - e_5,$$

$$B_1 - 2B_3 + B_5 = e_2 - e_4.$$

Using these two equations, along with (*a*), we find

$$B_1 = \tfrac{1}{6}\{e_2 - e_4 + \sqrt{3}(e_1 - e_5)\},$$

$$B_5 = \tfrac{1}{6}\{e_2 - e_4 - \sqrt{3}(e_1 - e_5)\},$$

$$B_3 = \tfrac{1}{3}(e_4 - e_2).$$

As an example, we shall take the periodic function represented in Fig. 32. Dividing the half-period into six equal parts, we find the following values of e:

$$e_1 = 9{\cdot}7\,;\ e_2 = 15{\cdot}06\,;\ e_3 = 9\,;\ e_4 = -2{\cdot}95\,;\ e_5 = -{\cdot}7.$$

Substituting these values in the expressions just obtained for A_1, B_1, etc., we find

$$A_1 = 8\,;\ A_3 = 0\,;\ A_5 = 1\,;\ B_1 = 6\,;\ B_3 = -6\,;\ B_5 = 0.$$

Hence the function is capable of being exhibited as the sum of the following simple harmonic terms:

$$8 \sin pt + 6 \cos pt - 6 \cos 3pt + \sin 5pt.$$

The first two terms, which represent two simple harmonic functions of the same period, may be combined into a single term (Art. 19), so that the given function may be written in the form

$$10 \sin (pt + \theta) - 6 \cos 3pt + \sin 5pt,$$

where $\tan \theta = \frac{3}{4}$. These three harmonic components are shown dotted in Fig. 32.*

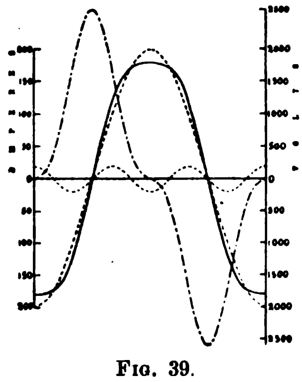

FIG. 39.

46. We shall next show how to apply the above method of harmonic analysis to the determination of the shape of the *current* curve when the E.M.F. curve is given. This method will be best understood by working out a numerical example.

In Fig. 39 let the chain-dotted curve be the given E.M.F. curve.* Dividing the half-period into six equal parts we find the following values of the E.M.F. corresponding to the first five points of division—

$$e_1 = 4{,}000\,;\ e_2 = 1{,}730\,;\ e_3 = 2{,}600\,;\ e_4 = 1{,}730\,;\ e_5 = 400.$$

Substituting these values in the expressions given above for A_1, B_1, etc., we find

$$A_1 = 2{,}000\,;\ B_1 = 0\,;\ A_3 = -600\,;\ B_3 = 0\,;\ A_5 = 0\,;\ B_5 = 0:$$

so that the E.M.F. is represented by

$$e = 2{,}000 \sin pt - 600 \sin 3pt.$$

Now the E.M.F.'s which act in any circuit are superposable—*i.e.*, each E.M.F. produces its own current just as if all the other E.M.F.'s were absent. The total resultant current in the circuit will be the algebraical sum of the currents due to the various E.M.F.'s in the circuit. Applying this principle to the case before us we may determine the currents corresponding to the simple harmonic components of the E.M.F., and then obtain the actual current by superposing these two.

We shall suppose, in the first place, that the circuit into which the alternating E.M.F. is introduced has negligible inductance, and that its resistance is 10. The impedance of the circuit will in this case be simply equal to its resistance, and the angle of lag will be nothing. Hence, the current in the circuit will be

$$200 \sin pt - 60 \sin 3pt,$$

and since the ratio of the amplitudes, and the phases, of the two simple harmonic components of the current are precisely the same as those of the E.M.F. components, it follows that the *shape* of the current curve will be precisely the same as that of the E.M.F. curve. The chain-dotted curve may, in fact, be taken to represent, to a different scale, the current. This result will obviously apply to any number of simple harmonic components, so that *when the inductance of a circuit is negligible, the current wave is of the same shape as the applied E.M.F. wave.*

We shall, in the second place, consider the other extreme case—that, namely, in which the *resistance* is negligibly small and the inductance considerable. Let the periodicity be 100 ~ per second (Art. 39), and let the inductance of the circuit be ·0159 henry (Art. 32). The impedance will now be simply equal to the reactance, and the angle of lag will be $\frac{\pi}{2}$—*i.e.*, a right angle (Art. 40). It must be remembered, however, that the reactance is a function of the periodicity. Hence, since $p = 2\pi n = 2\pi \times 100$, the reactance for the first harmonic term, $2{,}000 \sin pt$, is $pL = 200\pi \times {\cdot}0159 = 10$; and the reactance for the second harmonic term, $-600 \sin 3pt$, is $3pL = 30$. The *currents* corresponding to these two terms will therefore be

$$\frac{2{,}000}{10} \sin \left(pt - \frac{\pi}{2}\right) = 200 \sin \left(pt - \frac{\pi}{2}\right)$$

and

$$-\frac{600}{30} \sin \left(3pt - \frac{\pi}{2}\right) = -20 \sin \left(3pt - \frac{\pi}{2}\right)$$

respectively. These two harmonic currents are shown dotted in Fig. 39. The actual current in the circuit is obtained by superposing the two harmonic components, and is

$$200 \sin \left(pt - \frac{\pi}{2}\right) - 20 \sin \left(3pt - \frac{\pi}{2}\right).$$

This current is the full-line curve of Fig. 39, and the student cannot fail to be at once struck by the widely different shapes of the E.M.F. and current waves in this case: the one is a *peaked* wave, the other a *flat-topped* wave. Remarkable as this result may appear at first sight, it might have been predicted from purely physical considerations. For since the resistance of the circuit is negligible, we must at every instant have

$$\text{applied E.M.F.} = L\,i' \text{ (Art. 33)},$$

where i' denotes the rate of change of the current at the instant under consideration. It follows at once that if the applied E.M.F. has a very small value at any instant,

* It may be as well to point out that the curve of Fig. 32 is not the E.M.F. curve of any alternator; it has been chosen merely to illustrate the method of harmonic analysis given above. Some typical alternator E.M.F. curves are shown in Figs. 31, 33, and 39.

* See Fig. 37, which shows the component harmonics of this curve.

Digitized by Google

the value of i' must be correspondingly small. Now, a reference to Fig. 39 shows that over a certain portion of the E.M.F. wave—viz., in the neighbourhood of its zero points — the instantaneous values of the E.M.F. are extremely small; hence the corresponding values of i' must also be very small. In other words, the current varies very slowly during that time, and therefore its graph will be almost parallel to the axis of time. This is precisely what the curves in Fig. 39 show: the flat portion of the current wave corresponds to the hollow portion of the E.M.F. wave, over which the values of the E.M.F. are very small.

Another point which it is worth while to refer to in this connection is the following: If we compare the ratios of the *amplitudes* of the two component harmonics corresponding to the E.M.F. and current waves respectively, we find that the second harmonic term is relatively much greater in the E.M.F. than in the current wave—*i.e.*, the E.M.F. wave departs more widely from a pure sine wave than does the current wave. Hence one of the effects of inductance is to *smooth down* the *current wave** so that it approximates more closely to a sine wave than does the E.M.F. wave.

47. Since we suppose the circuit to be one of constant permeability, the current wave in Fig. 39 will also represent to a different scale the wave of magnetic flux. We thus see that a *peaked* E.M.F. wave gives rise to a *flat-topped* wave of magnetic flux in a circuit whose reactance is great compared with its resistance. If the student will draw the current wave corresponding to a flat-topped E.M.F. wave, he will find that the former is peaked. We thus arrive at the following result:

In a circuit whose resistance is small compared with its reactance a peaked wave of impressed E.M.F. gives rise to a flat-topped wave of magnetic flux, and vice versâ.

This result will also hold for a circuit containing iron, since the E.M.F. induced in any circuit is always measured by the rate of change of the magnetic flux through the circuit, quite independently of the medium in which the flux may be produced. The difference between the two cases lies in the shape of the *current* wave, which in a circuit of constant permeability is similar in shape to the magnetic flux wave, but in a circuit containing iron differs considerably from it.

(*To be continued.*)

ON THE SEAT OF THE ELECTRODYNAMIC FORCE IN IRON-CLAD ARMATURES.†

BY EDWIN J. HOUSTON, PH.D., AND A. E. KENNELLY, SC.D.

In the smooth-core armature of a motor, say, of the drum type, it is known that the electrodynamic force, which urges the armature around, is exerted upon the conductors wound thereon, and not upon the armature core. In such armatures the wires are apt to be turned or sheared around the core by the action of unduly powerful currents.

Fig. 1 represents the cross-section of a drum armature with 12 wires laid over its surface, and with the flux paths diagrammatically indicated, when the field is excited and current is passing through the armature. If the wires were free to move, like a cage, around the core, they would exert the entire torque of the motor, and, if hysteresis were absent, the core would have no tendency to rotate. The rotary effort of hysteresis in the iron core would necessarily be only a small fractional part of the entire torque of the motor, so that practically all the electrodynamic force exerted is upon the active conductors. When no current passes through these conductors, the magnetic flux is uniformly distributed through the air-gap over the surface of the field poles and armature.

The effect of passing the working current through armature conductors is twofold: (1) it produces a M.M.F. across the main magnetic circuit, thereby crowding the magnetic flux at the pole corners, *a* and *d*, and thinning it out at *b* and *c*, as shown; (2) it produces a distortion of the flux around each conductor, and it is this distortion which is the origin of the electrodynamic force on the conductor.

In the toothed-core armature it is generally considered that the electrodynamic force is exerted almost entirely upon the iron core and not upon the conductors. In other words, the function of the working current passing through the armature is to magnetise the iron armature core, and the field-magnet poles attract, so to speak, the magnetised core.

Fig. 2 represents a toothed-core armature situated in an excited bipolar field, but with no current passing through

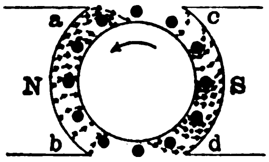

Fig. 1.—Bipolar Smooth-Core Drum Armature.

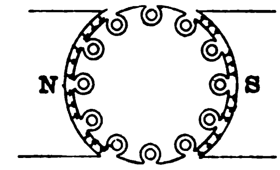

Fig. 2.—Bipolar Toothed-Core Drum Armature. Field Active and no Current in Armature.

the armature. Here the distribution of magnetic flux is uniform, as shown. Fig. 3 represents an active toothed-core armature in the same field. Here the flux is crowded together at the leading polar edge, as before, and thinned out at the following polar edge.

It is usual to consider that the iron core is magnetised by the current, so as to form, say, a north pole, *n*, beneath and a south pole, *s*, above, and that if the distribution of magnetic flux from a cylindrical magnet of this power were superposed upon the magnetic flux produced by the field, the resulting magnetic forces would have a torque identical with that of the electrodynamic forces indicated in Fig. 1. This view was, however, completely contradicted by the observations published in a paper by Prof. H. J. Ryan, on "A Method for Preventing Armature Reaction," read before the American Institute of Electrical Engineers in March, 1895 (*Transactions*, vol. xii., p. 84).

In carrying out his method of preventing armature reaction, Prof. Ryan applied an external M.M.F. on his

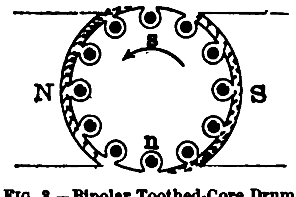

Fig. 3.—Bipolar Toothed-Core Drum with Armature Active.

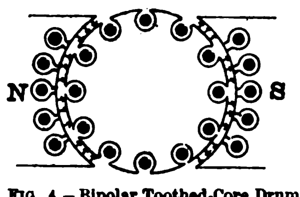

Fig. 4.—Bipolar Toothed-Core Drum Armature with Balancing Field Turns. Field and Armature Active.

toothed-core armature, equal and opposite to the internal M.M.F. developed in the armature conductors in the usual way. This was accomplished by cutting channels in the polar faces and embedding therein conductors which carried the armature current. By exploring the distribution of magnetic flux entering the armature, Prof. Ryan showed that when the balancing coils were left out of circuit the distribution was dissymmetrical, as indicated in Fig. 3, but that when the balancing coils were introduced with their opposing M.M.F., the resulting distribution of magnetic flux over the surface of the armature could be made practically uniform. In other words, the iron core of the armature was no longer magnetised as represented in Fig. 3; for the ampere-turns of the balancing coils, wound in the pole-faces, tended to produce a south pole where the ampere-turns on the armature tended to produce a north pole, and conversely. It was evident, assuming Prof. Ryan's observations to be correct, and they were too numerous to admit of experimental error in so fundamental a matter, that the armature core as a whole remained unmagnetised and yet the armature exerted its full torque. This is diagrammatically

* *Not*, be it noted, the induced E.M.F. wave (which in this case is equal and opposite in phase to the *peaked* applied E.M.F. wave). Failure to discriminate between the effects produced by inductance on the *current* and *induced E.M.F.* waves respectively has led to the remarkable fallacy, upheld by high authorities, regarding the "filtering" or "harmonic flywheel" effect of a transformer, or series of transformers, on an E.M.F. wave of irregular shape. It is only quite recently that Dr. Fleming has exploded this fallacy! Inductance *does* have a *smoothing* effect on the current wave, but *not* on the *induced E.M.F.* wave.

† From the *Electrical World* (New York).

represented in Fig. 4, where the distribution of flux over the surface of poles and armature is indicated as uniform.

The question therefore naturally arises, Does the driving force in the case of the toothed-core armature, with balancing turns, revert to the active conductors when the armature core as a whole ceases to be magnetised?

In order to answer this question, the authors have designed a small experimental motor, in which the conductors are embedded in tunnels carried through near the surface of the drum armature core. A front view of this motor is represented in Fig. 5, where it is seen to be a small bipolar machine. Fig. 6 represents the armature removed from the field. The armature is a solid cylinder of soft iron bored with 12 quarter-inch holes. The armature core is supported in brass straps bridging the pole-pieces. The conductors, 12 in number, are mounted in a cage having hard rubber faces or ends, which are capable of revolving freely upon the core shaft, through a small angular range—that is to say, within the limits of each core tunnel. There is no commutator, and the current was carried into and out of the conducting cage by flexible copper wires. Under these circumstances the armature core was free to revolve, and the armature conductors were also free to revolve independently of the core, but within narrow angular limits only. Two small pulleys were employed, one mounted on the core shaft and the other on the conductor cage, so that the torque exerted independently by each could be observed. The armature was never allowed to run and was only permitted to develop a torque through a very limited angular range of position.

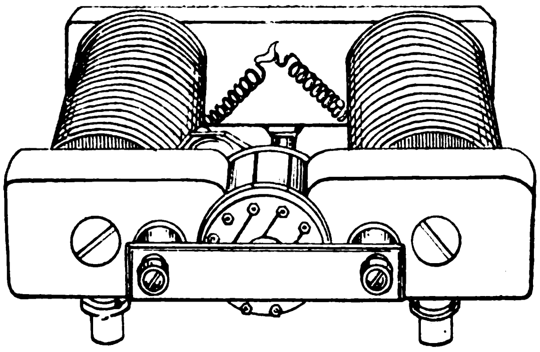

FIG. 5.—Front View of Experimental Motor.

The field magnets are of cast iron, and the pole-pieces are grooved with five parallel grooves for the reception of the balancing turns, as shown in Fig. 7. The field winding consisted of 648 turns of No. 19 B. & S. wire on each field spool. With a current strength of one ampere passing through the coils in series, representing a total field M.M.F. of 1,296 ampere-turns, or 1,629 gilberts, the magnetic flux passing through the armature was approximately 50,000 webers, and through the centre of the cast-iron yoke about 64,250 webers. The maximum intensity in the iron teeth of the armature was approximately 13·1 kilogausses.

It was found that the frictional torque of the armature core with the field unexcited was approximately 10·6 gm.-cm. The frictional torque increased when the field was excited to 42·4 gm.-cm., representing an hysteretic torque in the iron core of 31·8 gm.-cm.

When a current of 19 amperes, supplied by storage cells, was passed through the armature conductors, making five turns round the armature core, it was found that the magnetic torque on the iron core was 336·5 gm.-cm., and on the conductors only 5·4 gm.-cm.

Taking the total magnetic pull upon the armature core as 378·9 gm.-cm., the sum of the observed and frictional torques, the total magnetic torque on both core and conductors was 384·3 gm.-cm., of which 98·6 per cent. was exerted on the iron and only 1·4 per cent. on the conductors.

It was also found that the insertion of five turns of balancing coil wound in the polar faces did not perceptibly alter the torques developed at the core pulley and conductor cage pulley, indicating that the pull is still practically all exerted on the iron, whether the balancing conductors are employed or not.

In the same way, a small angular motion of the iron core induces in the conductors a transient E.M.F., while the same range and character of angular motion in the conductor cage produced a barely appreciable E.M.F., and this whether the balancing coils were employed or not.

The evidence derived from this experiment, together with the experiments detailed in Prof. Ryan's above-mentioned paper, indicate, that when balancing turns are employed, the iron core, as a whole, is not magnetised, but that the teeth are individually magnetised—that is to say, there is no dissymmetry of magnetic flux distribution over the surface of the armature core taken as a whole, but there is local dissymmetry of distribution on the surface of each tooth, whereby the flux is crowded at the leading edge and thinned out at the following edge of each tooth. By winding coils of insulated wire around the edges of the teeth, and connecting these coils with a ballistic galvanometer, we have observed that this action takes place, consequently the magnetic forces are locally exerted upon the teeth of the armature core.

If we accept this conclusion, it must follow that the distribution of magnetic flux in Fig. 4, although represented as uniform in so far that the same amount of flux enters each armature tooth as a whole, is not accurate in detail, since the flux passing into each tooth should be crowded at the advancing edge and thinned out at the following edge. Moreover, the same effects must be developed when no balancing turns are employed, as in Fig. 3, except that, in addition to the local dissymmetry at each tooth, there is an additional total dissymmetry over the surface of the entire armature.

The final conclusions appear therefore to be as follows: (1) The distribution of magnetic flux over the polar surface

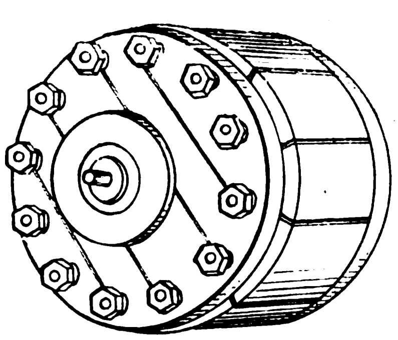

FIG. 6.—Armature of Experimental Motor.

of a toothed-core armature may be regarded as practically uniform when no current passes through the armature. (2) When the working current passes through the armature coils two effects are produced—viz.: (*a*) a local dissymmetry of magnetic flux in each tooth whereby the flux is crowded at the advancing edge and thinned out at the following edge; (*b*) the M.M.F. of the armature as a whole distorts the general distribution of the flux over its surface. (3) When balancing coils are employed, the main distortion just alluded to under (*b*) may be annulled, but the local dissymmetry (*a*) is only slightly modified and remains in full force.

Reflector for Street-Lighting. — Mr. W. H. Kincaid, of Santa Barbara, California, has invented a special arc lamp reflector for use at street crossings. The object of the lamp at a right angle crossing of two roads is, the inventor thinks, to light the roadways only. If, therefore, the light issuing from the lamp can be confined to the roadways by reflectors, an increased lighting effect should be obtained. He effects this by means of four vertical reflectors whose horizontal sections are parabolas. The arrangement of reflectors is shown in the current number of the New York *Electrical Engineer*. From the diagrammatic sketch we gather that the arc would never be visible from any point, but that the whole of the light is reflected by the mirrors. If the mirrors are accurately designed, the result would be to give four narrow beams of light. The width of the beam would also be much more narrow than the roadway. The strong local light thus obtained would be very objectionable from a driver's point of view, and we cannot see that the invention is likely to find favour.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 11d.	9s. 9d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XVI. of new series of "The Electrical Engineer" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

STATE-OWNED TELEGRAPHS.

The comparison between the telegraphic service in two countries so widely different in extent and in density of population as Great Britain and the United States of America is no easy task if justice is to be done to both sides. Again, if the question of the influence of State ownership is to be added to the comparison, any conclusions neglecting the difference between the constitution of the countries is valueless. We notice that Mr. W. J. Bryan, the democratic candidate for the presidentship of the United States, has included the State ownership of telegraphs and telephones in his programme. Certain of the technical papers have accordingly taken him to task, and at the same time have depreciated the telegraphic service of this country. The chief point found fault with is our annual deficit, which, for the year ending March, 1895, amounted to about four hundred and forty thousand pounds. The question for the technical papers is rather that of the cost of the service than the price fixed by the Parliamentary representatives of the people. The telegraphic system in America is practically in the hands of the two large companies called respectively the Western Union and the Postal Telegraph Companies. These two powerful companies compete in certain districts, but the rates are not subject to competition. As a result, the company showing the best despatch in its business gets most custom, and in certain cases an exceptionally good service is given in consequence. The annual expenditure of those companies averages about 70 per cent. of the the gross receipts. The remaining 30 per cent. is, of course, distributed in capital charges, interest, and direction expenses. In England, with Government control, for the year ending March, 1895, the expenditure exceeded the receipts by about 5¼ per cent., and after adding the capital charges, the deficit rose to about 17 per cent. of the receipts. Looking at the question as above, the favour of the business man turns to the paying concern. The other side of the question, however, needs careful consideration. What does the general public have to pay for its telegraphic facilities? In America the average cost of a telegraphic message is practically double that in England, while the cost of a press message of a given length is seven times dearer in America than here. We need hardly refer to the fact that a readjustment of the price for Press telegrams only would wipe out our present deficit. In fact, our press telegraph service is carried on at a loss, and there is little doubt but that the ordinary telegraph message is remunerative. The higher rates in America and the extended area to be covered has in that country practically kept the telegraph service out of reach of the average household. Thus the two competing companies devote their chief attention to cities where the large number of messages repays them for their outlay. The smaller towns suffer from the lack of competition, and in the average village the telegraph is seldom installed. As a consequence business communications receive prompt attention, but any service other than a main route suffers. In

Digitized by Google

England, under the control of the Government, a good service is maintained everywhere. The small and often non-paying stations receive adequate attention, so that the time taken in sending a message to any place is not dependent on the importance of that place. The whole telegraphic system is considered rather as a public convenience than as a money making concern. One other point needs attention in reference to the annual deficit shown in the account. On examination it will be seen that the capital charges do not increase. In other words, all extensions are charged not to the capital account, as is the custom in commercial businesses. Thus the extensions, of which an enormous number have been carried out since 1870, have been charged to the annual expenses. This is hard on the annual balance-sheet, comparing revenue with total expenditure, and must be borne in mind when talking of the deficit. It is absurd to suppose that the capital value of our telegraph equipment has stood still for the last twenty-five years. We conclude that the average English service is both better and much more cheap than the average service in America, and that this is due in no small measure to State control. The difference in the density of the population tends to explain the greater cost of the American service. The question as to whether State control would cheapen and improve their service is dependent on the organisation of the control. We think it would not if the department is to be run on political lines, with a chaotic period at every presidential election due to changing all the chief officials.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

LIGHT LOCOMOTIVES.

Sir,—After a long period of labour, the "Locomotive on Highways Bill, 1896," has become an Act, and probably at no period in the history of the English Legislature has so liberal a measure been passed; indeed, the President of the Local Government Board cannot be charged with a want of faith in humanity, believing, as he must do, that no abuses will follow the help he has so freely extended to the new movement.

For the great freedom given in this measure I feel that I am in a large degree responsible, Mr. Chaplin and the officials connected with the Local Government Board and the Home Office having accepted the various points which I advocated in person and in writing, as well as the amendments which were finally adopted in committee on Mr. Chaplin's recommendation, and those which were not opposed by him at that committee.

In rendering all the assistance in my power to those who had charge of the Bill during its passage through the Houses of Parliament, and to those whose duty it now is to make regulations in connection with this Act, my hands were immensely strengthened by the support received from so many distinguished and eminent men conversant with the subject—all, like myself, entirely disinterested and unbiassed by personal or pecuniary motives. These gentlemen include statesmen, engineers, scientists, and a host of others.

My object in requesting the publication of this letter is, on the one hand, to express the gratitude of all those I represent in this movement to the Government, to the permanent officials of the departments concerned, and to all others by whose labours and influence success has been obtained; and, on the other, to appeal to everyone interested in the movement, whether as manufacturers or users of motors, to do nothing on their part to abuse the freedom which has now been extended to them. It behoves everyone concerned to act with prudence and consideration; to avoid injury to the roads; to use every possible care not to frighten horses; to store no dangerous liquids thoughtlessly, which might endanger life or property; and to act generally with such discretion that it shall not be said in a year or two hence, another Act must be passed to control those who have shown their inability to control themselves or have misused their privileges.

There cannot be the slightest doubt in the mind of any reasonable man that this Act will be productive of great changes, and that if all those who have an interest in modern progress will strive to improve self-propelled traffic, and those who avail themselves of its benefits will act fairly towards others having no direct interest in the movement, it will be giving the English nation an advantage which can hardly be overrated and without entailing, as I hope and believe, a vestige of discomfort or annoyance on any individual.—Yours, etc.,

David Salomons,
President, Self-Propelled Traffic Association.
Offices of the Association, 30, Moorgate-street,
London, E.C., August 15, 1896.

THE PLYMOUTH REPORT.

Sir,—I have read with much interest the report of Mr. J. H. Rider to the Electric Lighting Committee of the Plymouth Corporation on the question of the electric supply for lighting and traction purposes. It would be very interesting to many, and particularly so to myself, if Mr. Rider would publish the detailed figures showing how he arrives at the cost of electric traction at 6d. per car mile, with current alone costing 3½d. per car mile.

I enclose my card, and subscribe myself as

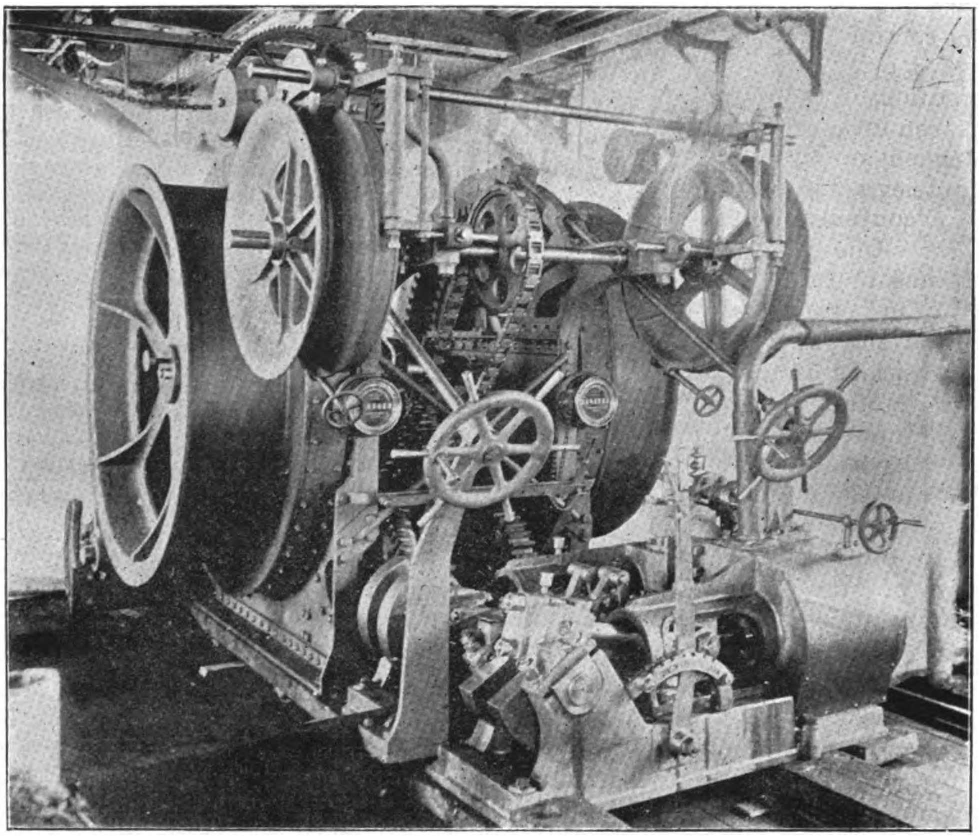
One Seeking after Knowledge.

THE NEW ZEALAND GOVERNMENT CABLE SHIP "TUTANEKAI."

The above-named vessel, which was built for the Government by Messrs. Dunlop and Co., of Port Glasgow, is designed for several purposes, the most important of which is the repairing of the New Zealand Government cables. Messrs. Johnson and Phillips, of Charlton, who make a speciality of cable laying and repairing machinery, were entrusted with the complete outfit of apparatus, accessories, and stores for this purpose. One novelty in the design of all the deck, cable machinery, and fittings supplied for this vessel, is that it can all be easily removed, so that when the ship is not required for cable purposes the whole of it can be taken away and put into store, leaving the decks free. All the holding-down boltholes are provided with sockets, into which plugs can be screwed so as to leave the deck perfectly watertight when the gear is removed. The picking-up and paying-out machine, illustrated herewith, is extremely compact, though it is a double machine. It is designed to pick up cables under a strain of 20 tons. It only weighs 9¼ tons, and only occupies a deck space of 8ft. 3in. by 11ft. 6in. It is very similar in design to the gear recently fitted by Messrs. Johnson and Phillips on the Japanese Government steamer, except that it is not quite so powerful and has horizontal engines instead of vertical. The machine is built on two frames made of steel plates, with steel angles inside and outside with welded corners. The drum shaft, which has large collars welded on for attachment to the frame, ties them well at the top. The forward bottom ends are tied by a steel plate and also by a flange shaft, which carries the fleeting knives, and takes the eyes of the main brake straps. There is also a "T" stay bar at the bottom after-end, as well as diagonal stays at each end of the pairs frames. This makes a very stiff job, and allows of the

Digitized by Google

whole of this part of the gear being lifted out in one piece without fear of the shafts or bearings getting out of line. The machine is designed for two speeds, which can be geared on to either drum, but the port drum only is intended for the heavy lift of 20 tons. It is accordingly built of steel, whereas the starboard drum is of cast iron. These drums are 6ft. 7in. diameter by 2ft. wide over all. They are internally geared, and have a rim cast on for the main brake; hence they combine the main drum, brake drum, and gear wheel in one. These drums are arranged to run loose on the shaft, and are capable of different combinations with the gearing as follows: Both drums can work loose without the engine; both drums can work at the same speed with the engine; one drum can be driven by the engine while the other runs independently; one drum can be held by the brake while the other is being worked by the engine; power of both brakes can be put on to one drum by keeping the pinions in gear. All wheels are arranged to draw out of gear where possible when not required for driving, so as to avoid rattling. In the case of the pinion which gears with the large drums, this necessitated cutting large holes in the frame, so that the pinion could pass right through them. The frames at these parts are provided with large circular cast-iron pockets which carry bearings at each end, so that when the pinion is in work it is close up to a bearing, thus ensuring a very sound job. The brakes consist of steel straps with elm blocks attached, the ends of the straps being fitted with steel castings which carry nuts with right and left hand threads to take the brake screws. The screws and rods are taken down to the after end of the machine, so as to be worked from the main deck. The lower part of the brake strap is fitted with a large cast-iron eye, which transmits the strain to the lower part of the machine frames by means of a steel shaft, which is secured to the frames by large cast-iron flanges.



The Johnson and Phillips Picking Up and Paying Out Gear Fitted to ss. "Tutanekai."

Hauling-off gear is driven by chain from the intermediate shaft, so that its speed is always proportionate to that of the drums. For holding-back purposes the sheaves have a brake rim cast on them, and on these rims a steel strap with screw adjustment is fitted so that the amount of "drag" put on the cable can be adjusted minutely. The sheaves can slide along on their shaft to suit an inside or outside lead. A small Worthington pump is fixed between the frames to supply the main and holding-back gear brakes.

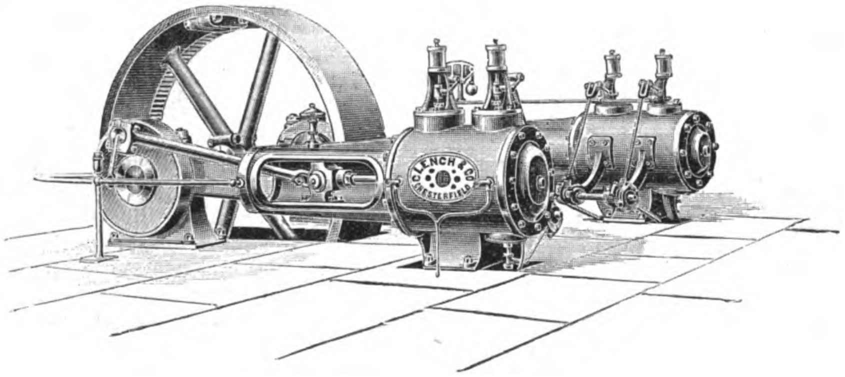


FIG. 1.—General View of the Clench Horizontal Engine.

The engine has cylinders 9in. and 16in. by 10in. stroke suitable for steam 160lb. per square inch, and it is complete with automatic bye-pass valve, steam valve, and link motion reversing gear, all of which, with the main and holding-back brakes, are within reach of one man at the after end of the machine. The gear was run under steam pressure at Messrs. Johnson and Phillips's works, and also on board the vessel to the satisfaction of the consulting engineers, W. H. Preece, Esq., and W. R. Culley, Esq., of

Digitized by Google

H.M.T.S. "Alert." The bow gear consisted of two steel sheaves, 3ft. 2½in. diameter by 11½in. wide, which run loose on a steel shaft supported in cast-iron brackets attached to three steel girders. Each sheave is provided with cast-iron whisker guards to prevent the cable getting off the sheave, these guards also being bolted securely to the whiskers. The girders are fitted with eyes and bollards to secure the stoppers. A davit is provided between the sheaves for launching mushrooms, etc., and is arranged to fold down out of the way when necessary to let go the "bight."

The vessel is fitted with the usual dynamometers, lead wheels, deck leads, troughing, etc., and is fully equipped with a complete outfit of stores and accessories, including grapnel and buoy ropes, grapnels, mushrooms, buoys, chains, sounding shot, steam sounding machine, steam hauling gear, etc., and the testing room is provided with a set of first-class instruments.

THE CLENCH HORIZONTAL ENGINE.

We are indebted to Messrs. Clench and Co., of Lincoln Works, Chesterfield, for the following particulars of their new type of horizontal engines which has been designed for electric lighting purposes. Fig. 1 shows a general view of the engine, which is of the cross-compound type, with the high-pressure cylinder on the right-hand side when standing at the cylinder end.

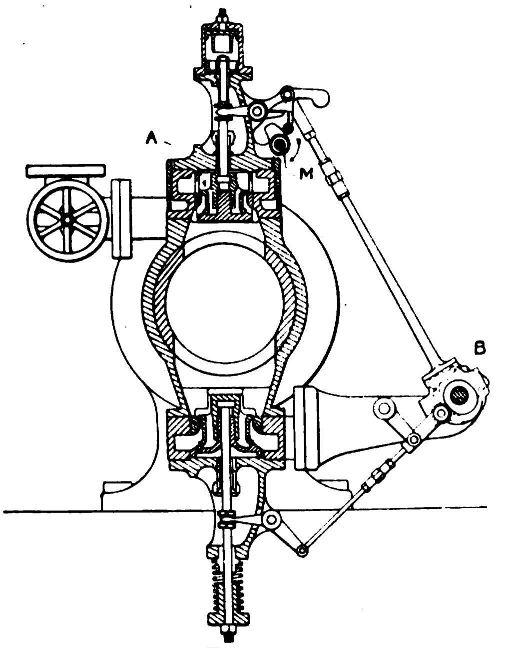

Fig. 2.

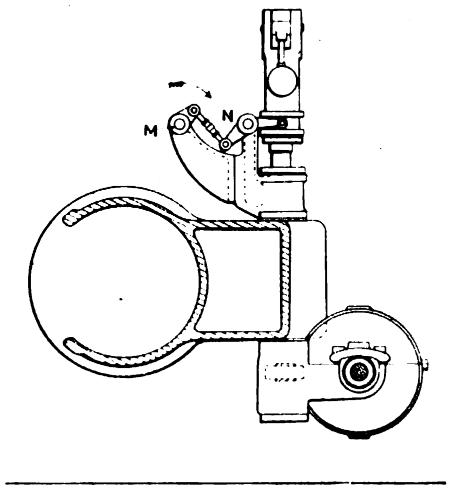

Fig. 3.

Each cylinder is jacketed with high-pressure steam, as is also the intermediate receiver. A by-pass valve is arranged to admit steam directly from the high-pressure supply into the low-pressure cylinder, so that the engine can be started in any position. The valve gear is the special feature of this engine. It is of the Clench patent trip-gear type. A good idea of the construction of the gear can be obtained from Figs. 2, 3, and 4. This valve gear, by reason of its simplicity, overcomes the chief objection to the use of the double-beat equilibrium valve for the distribution of steam in the cylinder of an engine. At the same time it secures practically a constant lead, instantaneous cut-off, and freedom of action for the governor, in a degree the makers claim has been never before obtained by the usual and more complicated arrangements. Figs. 2 and 3 show the side elevations and sections of the engine and cylinder with the valves and gear.

Fig. 4 is an enlarged view of the lifting levers showing the trip arrangement. The valves, A A, are raised each by an eccentric, B or C, on the lay shaft, D, which is driven by skew gears from and revolves with the engine shaft. The eccentric is connected through a fork to a pair of loose links, F, between which lie the lifting levers. Engagement is made with the lifting lever by the hanging link, H. The bottom end of link H is prolonged and carries a roller, J, which as the link descends comes in contact with the cam, K, which releases the lifting lever and allows the spring, L,

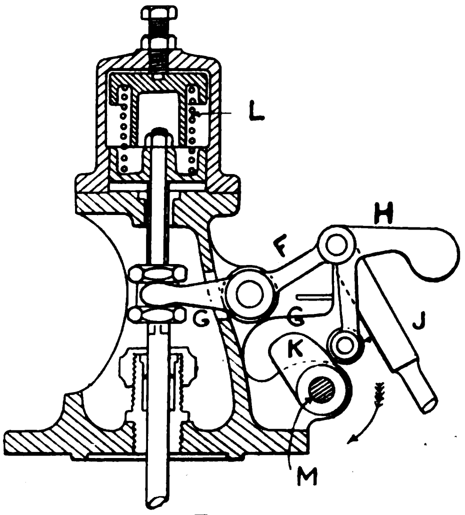

Fig. 4.

to close the valve. The valve is prevented from closing with too great force by an air cylinder and clack. The automatic closing of valve is effected as follows: The spindle, M, carrying the cam, K, is connected by the links, N, as shown, to the governor. The governor in rising turns the spindle with the cams in the direction indicated by the arrow, causing the roller, J, to come in contact with the cam, K, and so releases the valve at an earlier period of the stroke. Thus the governor regulates the position of the cam to give an earlier or later cut-off according to its position, which is according to the speed of the engine. The exhaust-valves are, like the above, of the double-beat equilibrium type, and are operated by cams on the lay-shaft as shown.

ALTERNATE-CURRENT TRANSFORMERS.*

BY DR. J. A. FLEMING, F.R.S.

LECTURE IV.

The Employment of Transformers.

In this last lecture I wish to direct your attention to certain problems in connection with the employment of transformers. I shall assume that the majority present are quite familiar with the ordinary methods of distributing electric current by means of transformers, whether by what is called the system of distri-

* Cantor lectures delivered before the Society of Arts.

Digitized by Google

bution by house transformers, as shown in Fig. 47, or the more modern and economical method by transformer sub-stations. Generally speaking, the method of transformer distribution which is now found to be most practically useful in provincial towns and over large areas is somewhat as follows: In the generating station, the alternators either send their current into one common set of omnibus bars, the alternators working in parallel, from which bars a distribution is made by high-tension feeders to various transformer sub-stations; often a more complicated switchboard is employed in which the high-tension feeders coming from the various transformer sub-stations can be connected at pleasure to any alternator, or grouped together in any way on one or more of the alternators. It would be foreign to our subject here at the present moment to enter at all into the question of the parallel-working alternators. It has been fully discussed in the technical journals and other publications. The high-tension feeders are generally arranged to convey a high-tension current at a pressure of 2,000 volts to certain transformer sub-stations in which are placed a bank of transformers. These transformers take their primary current through primary switches and fuses from primary omnibus bars connected to the feeders, and the secondary circuits of the transformers are generally arranged to feed a three-wire system of low-tension distribution. For this purpose each transformer is provided with three secondary terminals, and from the sub-station proceeds a three-wire low-tension system which is fed by one or more of the transformers, and to which the consumers are connected. In joining up a bank of transformers in this manner it is important that each of the transformers should have an equal percentage secondary drop for the same fraction of full load. Otherwise, if one transformer has a smaller secondary drop than another that transformer with the least secondary drop will take the greatest share of the load as the sub-station is loaded up, and it may, therefore, get overloaded and get very hot, and such an inequality of load tends to increase the more the bank of transformers is loaded up. It is always advisable to examine transformers in this manner, and if any transformer is found to have too large a secondary drop then to remedy it by adding one or more turns to the secondary circuit. In addition to a low-tension distribution from transformer sub-stations it is sometimes found convenient to run one or more high-tension feeders to supply the outlying regions of the district which is then served with a system of house transformers. The plan which I have found convenient to adopt in developing an alternating-current station in a provincial town in which there is a central shop district, in which the lighting is rather dense, and an outlying residential district in which it is rather scattered, is to arrange one or more low-pressure secondary networks on the three-wire system in the central portion of the town. Each of these networks is fed from a single transformer sub-station, and the secondary circuit forms a complete ring main, which is fed into by secondary feeders at three or four places. The transformer sub-stations are inter-connected by a high-pressure connecting main, which serves, in case of breakdown at one station, to allow the duty of that station to be taken up by another sub-station. It is not advisable, in my opinion, to connect together the different separate secondary networks. One great advantage of the alternating-current system is that it enables us, by having small separate secondary distribution systems perfectly insulated from one another, to limit the effect of a dead earth on one of these secondary networks, and that is an advantage which cannot be obtained on the ordinary low-pressure system, where the distribution network is connected throughout.

As regards the description of cable to be employed, it is now well understood that concentric cable forms in all cases the most satisfactory of cable both for the high-pressure and the low-pressure conductors. By the employment of concentric cable, we eliminate at once any difficulties which would arise due to induction taking place on neighbouring telegraph and telephone wires; and we also largely reduce the inductive drop in pressure which would otherwise exist if the three members of the secondary circuit were separate cables separated by any distance from one another. My own experience is that the secondary network is best laid down by means of triple concentric cable, and there are certain advantages in making the outer member of this cable the middle wire of the three-conductor system. In any case, the house connections are quite easily made. It is also desirable to get rid altogether of distribution boxes and service boxes, which become localities in which coal gas can collect and occasionally explode. In laying down the secondary distribution system by means of lead-covered and armoured triple concentric cable, by far the best plan is to make the proper connection with a service main to each house at the time that the cable is laid, and to have this joint entirely sealed up in lead, making use of no junction-box, or at most of a right-angle iron sleeve to mechanically protect the joint. The service main can then be taken into each shop or house, and connected up to the consumer's terminals, whether the building takes light or not. In the central portions of a town it is only a question of time for every shop or house to take the current, and it saves expense ultimately to make this joint in the first instance. The secondary cable having been laid in this manner should be tested, and my own practice is to insist upon a test of 1,000 volts between the different members of the secondary circuit when it is laid in the earth, but before the house connections are made. If the cable stands this test, it has a large factor of safety. With regard to the high-pressure cable it is customary to use ordinary duplex concentric cable, and if the service is a 2,000-volt service, then after the cable has been laid in the ground it should be tested by a pressure of 4,000 volts placed between the inner and outer members for one hour, and a pressure of 2,000 volts between the outer member and the earth, and the cable should not be accepted unless it has passed this test. As it is always desirable to use concentric cables in connection with all modern transformer systems of distribution it is necessary to pay attention to some peculiar effects which are observed in connection with concentric cables when supplying transformers, and during the remainder of the lecture I propose to occupy your attention chiefly with practical points connected with these effects. They may be divided into four classes. There are first those which may be called the resistance effects, which are effects connected with the distribution of the current over the cross-section of the conductor employed for the transmission of the alternating current. Secondly, there are the capacity effects, which depend upon the fact that a concentric cable is a large condenser or Leyden jar. Thirdly, there are the resonance effects, which are due to the reaction of this capacity upon the alternators or the primary transformers. Fourthly, there are effects which may be called the initial stage effects depending upon the capacity of the cable and the inductance of the transformers supplied through it, both of which co-operate together to produce peculiar effects at the moment when the cable carrying the transformers is switched into connection either with another live cable or with an alternator. We shall consider each of these in turn. It will be necessary to preface a detailed discussion of these effects by some general remarks upon the nature of current flow in inductive circuits. Every electric circuit which has self-induction or inductance and capacity has a natural period of electric vibration—that is to say, if the electric charge in it is disturbed and then left to itself, it oscillates backwards and forwards as water would do in a long tube having the ends closed by elastic caps. In such a case, if the water was disturbed and then left to itself, it would oscillate to and fro in virtue of the fact that the mass of water possesses inertia, and that the elastic caps on the ends of the pipe permit the water to be displaced. In other words, such a closed pipe has what may be called hydraulic inertia and permittance. In the same manner a circuit which has self-induction possesses what may be called electric inertia or inductance, and a condenser which permits of electric displacement to be made through its dielectric or non-conductor has what is called capacity or permittance. If a condenser with a capacity, C, is being charged through a resistance, having a value represented by R, the product, C R, is called the time-constant of that system, and it represents the time in which the charged condenser, if left to itself, short-circuited by the resistance, R, would fall in potential, to a certain fraction (very nearly two-thirds of its original potential); again, if L is the inductance of a conductor and R is its resistance, then $\frac{L}{R}$ is called the time-constant of that circuit, and this is the time in which a current in that circuit would rise to about two-thirds of its full value if a constant E.M.F. is put upon the ends of the inductive resistance. The first product, C R, is called the electrostatic time-constant of the condenser and resistance, and the quotient, $\frac{L}{R}$, is called the electromagnetic time-constant of the inductive resistance. If, then, we join together in series a condenser having a capacity or permittance, C, and an inductive resistance having an inductance, L, and a resistance, R, it can be shown that the complete, free, periodic time of oscillation of a charge of electricity in that system is given by this expression:

$$t = 2\pi\sqrt{\frac{L}{R}\,C R}.$$

In other words, the complete periodic time is equal to 2π times the geometric mean of the electrostatic and electromagnetic time-constants. It must be noted that this is the time of oscillation of the charge when left to itself, but it is, of course, perfectly possible to make what is called a forced oscillation, and that is what is done in every transformer system. These electrical quantities have their mechanical analogues. Suppose, for instance, we take a pliable lath with a weight on it, and fix it at one end, the pliability of the lath is the analogue of the capacity of the electrical system, the mass of the weight on the end is the mechanical analogue of the inductance of the system. If, then, we displace the lath or bend it, and leave it to itself, it vibrates to and fro with a natural period of its own, in virtue of the

Digitized by Google

fact that the system has pliability or permittance, and mass or inductance. If the mass be small and the pliability is small the time of vibration is small, but if the pliability is great and the mass is great, then the time of vibration is great. Such a loaded flexible rod not only has a free period of vibration of its own if fixed at one end and set in oscillation, but we may give it a forced oscillation. Before explaining the manner in which certain electrical effects may be mechanically imitated by such a loaded lath, we will consider a little more in detail the properties of concentric cables when used with alternating currents. In the first place, a cable intended for use with an alternating current must not have the metal or conductor of which it is made of a thickness exceeding a certain value, for the reason that a certain time has to elapse before the current is established in the central portions of the conductor, and therefore if the conductor is used with alternating currents, its actual resistance depends upon the frequency and the thickness of the conductor. Without going into more elaborate explanations on this point, for which I refer the reader to other text-books, I may give here a table showing the resistance of high conductivity round copper conductors to continuous and alternating currents of a certain frequency, the results of which are set out graphically in a curve in Fig. 48.

The following table shows us that practically the largest conductor which should be used in connection with alternating-current work is a cable having an outside diameter equal to a $^{19}/_{12}$ cable, and that if the cable has a greater diameter then its resistance to alternating currents of a frequency 100 is sensibly different from its resistance to continuous currents. In the next place, with regard to capacity, suppose that a concentric cable is formed by putting one cylindrical tube in the interior of another cylindrical tube, the space between the tubes being occupied by a non-conducting material or dielectric having a specific inductive capacity equal to K, then if R_0 is the radius of the inside of the outside tube, and R_1 is equal to the radius of the outside of the inner tube, and if L is the length of the tubes, the capacity of this concentric cable in microfarads is given by this expression:

$$C = \frac{K\,L}{2\,(\log R_0 - \log R_1)\,2{\cdot}303 \times 9 \times 10^5}.$$

Then as regards the value of K for paper insulation, such as is used in the Ferranti cables, K has a value very nearly equal to 3; but if indiarubber is used, then K has a value very nearly equal to 4. On calculating out these values for most ordinary cables used for the conveyance of high-tension alternating currents, it will be found that for such insulating materials as paper Fowler-Waring composition, or various resinous substances, the capacity of the cable is generally about one-third of a microfarad per mile.

TABLE OF RESISTANCE OF HIGH-CONDUCTIVITY ROUND COPPER CONDUCTORS.

From what has been said above with regard to the resistance effect it must be noted that in the construction of a concentric cable the maximum thickness of the copper conductor cannot be more than about ½in. In cases where larger currents have to be conveyed than can be carried through the equivalent of a $^{19}/_{12}$ cable it is desirable to employ two concentric cables in parallel. Let us consider, then, the capacity effect. If a long concentric cable is connected to an alternator, the far end of the concentric cable being insulated, it is found that an electric current flows into and out of the cable, which may be sufficient to light one or more incandescent lamps. This is called the capacity current of the cable, and it is a current flowing across the dielectric or non-conductor from one copper member to the other. If C is the capacity of the cable measured in microfarads, V, the difference of potential between the two copper members measured in volts, and if p represents $2\pi n$, where n is the frequency, then the capacity current, I, is given by this expression:

$$I = \frac{C\,p\,V}{10^6}.$$

Thus, for example, supposing a cable, having a capacity current one-third of a mile capacity, has a potential difference of 2,000

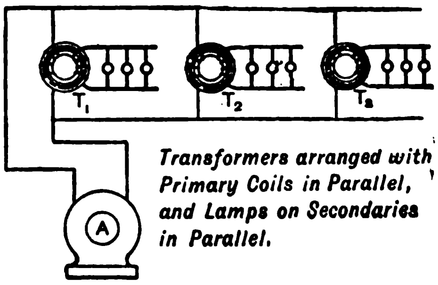

FIG 47.

volts between its inner and outer conductors, and p equals 500, then the capacity current is one-third of an ampere, or equivalent to the lighting current of one 8-c.p. lamp. Hence, in very large concentric systems, this capacity current going out of the station may amount to a considerable value. We have then to consider briefly what are called the resonance effects. If an alternator is separately excited so as to give a certain potential difference at its terminals, suppose 2,000 volts, and if a long length of concentric cable is connected to this alternator, the far end of the cable being insulated, then it will be found that such cable, when associated with the alternator, may greatly increase the electric pressure between the terminals of the alternator, and that for a certain critical length of the cable a very marked rise in pressure may take place. The same will be found to be the case if a long length of concentric cable is connected to the high-pressure side of a step-up transformer being excited from a 100-volt alternating circuit on the low-

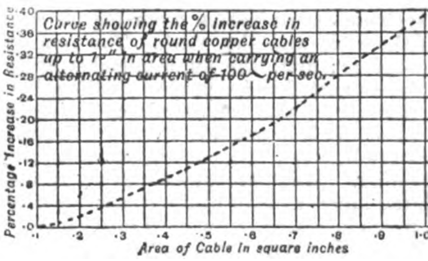

FIG. 48.

pressure side. Accordingly, in testing concentric cables, the engineer must always be on his guard against this resonance effect. Suppose, for instance, it is desired to test whether a certain length of concentric cable will stand 2,000 volts, the most natural method of doing this would be to connect the high-pressure side of a step-up transformer, raising the volts from 100 to 2,000, and to serve the low-pressure side of this transformer from a 100-volt circuit. The inexperienced person might naturally suppose that this would invariably place upon the cable a pressure of 2,000 volts, but under certain conditions, depending upon the capacity of the cable and the inductance of the transformer, the pressure might rise far beyond 2,000 volts between the two members of the cable, and the only method of making sure that this is not the case is to have an electrostatic voltmeter kept connected between the inner and outer members of the cable as the pressure is gradually increased.* Then, in the last place,

* For a further discussion of these resonance effects the reader is referred to "The Alternate-Current Transformer," Fleming, vol. ii., p. 383, *et seq.*, where a full discussion of these effects in connection with concentric cables is given.

Digitized by Google

not only are there the resonance effects above referred to, by which a concentric cable when switched on to an alternator or transformer permanently raises the pressure, unless the exciting current of the alternator is reduced, but there are certain very important initial effects which take place at the moment when a concentric cable is switched into connection with either an alternator or another live cable. If a condenser is connected with an inductive resistance, it can be shown that at the moment when this system is brought into connection with the source of alternating E.M.F., if the connection is made at a particular instant with respect to the phase of the E.M.F., there is an electrical oscillation set up in the combined condenser and inductive resistance, the amplitude of the oscillations of current greatly exceeding those which would exist when the steady state has been established, and oscillations of potential difference occur at the same time, the result of which is that the difference of potential between the two plates of the condenser will undergo a periodic change, the amplitude of the oscillations of which is, however, in the initial stage much greater than that of those which take place when the whole system has settled down into a steady condition under the influence of the impressed periodic E.M.F.

Suppose, then, that a series of transformers are connected to the two copper members of a concentric cable, and that the concentric cable is, as usual, lead covered and steel armoured with a layer of insulation between the lead covering and the outer copper members. As already stated, there is a certain capacity in the concentric cable between the inner and the outer members, which will be generally something like one-third of a microfarad a mile, but, at the same time, there will be a capacity between the outer member of the concentric cable and the lead casing or the earth, and this capacity between outer and the earth, as it is called, is very much larger in general than the capacity between the innner and outer; it may be 10 times as great. Hence, if the transformers are connected between the inner and outer conductors, we may regard the primary circuits of the transformers, which are inductive circuits, as connected in series with a condenser, which is formed of the outer members of the cable and the lead covering. If, therefore, such a cable, with transformers attached to it, the secondary circuits of which are unloaded, is switched into connection with the omnibus bars of an alternating-current station, the connection between the inner member of the cable with the proper omnibus bar being made first, then, at that instant, an E.M.F. is impressed upon the system, consisting of the inductive primary circuits and the condenser in series with them. For a particular phase of the impressed E.M.F. it can be shown that oscillations of potential are set up in the condenser, causing a periodic potential difference between its two sides to be greater than that due to the steady action of the periodic E.M.F. This sometimes results in breaking down the insulation between the outer members of the concentric cable, and the lead covering, and as this insulation is generally in all cases made much thinner than that between the inner and outer members of the cable it is not unfrequently pierced. Alternating-current station engineers are very familiar with failures of such concentric cables occurring between the outer members of the cable and the earth. The remedy for this is one of two things: first, the outer member of the concentric cable must be connected to its proper omnibus bar first before the inner member of that concentric cable is connected. If this is done, then it is impossible to set up destructive oscillations of pressure between the outer members of the cable and the lead covering. Another remedy is to introduce in the circuit with the inner member of the concentric cable a variable inductance which is gradually removed in such fashion that the inner member of the concentric cable is not connected suddenly with the source of potential, but is connected through a choking coil, the choking quality of which is gradually removed. This can be done in the following manner: a large transformer is arranged so that its secondary circuit can be gradually short-circuited by lowering two lead or iron plates into an insulated tub of water; the primary circuit of this transformer can be connected in series with the inner member of the concentric cable which is to be brought into connection with the system. The operation, then, of connecting the long concentric cable to the omnibus bars is as follows: The series transformer first has its secondary circuit opened; its primary coil is then connected in series with the inner members of the concentric cable to be connected, and with the proper omnibus bar; the outer member of the concentric cable is then connected with the other omnibus bar; the plates on the secondary circuit of the series transformer are then gradually lowered into the water, and when the secondary circuit of this series transformer is practically short-circuited the primary circuit of the transformer is also short-circuited, and the transformer is then removed, leaving the main in connection with the omnibus bars. The operation, moreover, is performed in such a manner that there is no rush of current into the cable, and no possibility of setting up violent oscillations of potential between the outer members of the concentric cable and the earth. In no case should long concentric bars be connected to omnibus bars or to other parts of an alternating-current system without some such process as the above of gradually setting up the full current in them, or else the risk of piercing the outer insulation of the concentric cable is very considerable. Engineers in connection with alternating-current stations should always be on their guard against these initial effects, and remember that long concentric cables, with transformers connected to them, possess a quality which resembles inertia, and that currents can no more be started and stopped instantly in these cables and transformers than heavy machinery can be started and stopped at once.

In addition to the initial effects taking place in cables, I showed, in 1892, that there were certain initial effects, called current rushes, taking place in transformers when suddenly switched into connection with a live cable. Under some circumstances, depending upon the phase of the E.M.F. in which the switch is closed, a strong rush of current may take place into the primary circuit of a transformer, the maximum value of that current rising to twice the maximum value of the current when the steady state is established; and, under some conditions, in switching off a transformer, there may be a certain rise in the difference of potential between the parts of the primary circuit and the iron case or secondary circuit which may pierce the insulation. If a large current is flowing in an inductive circuit, and a switch is suddenly opened, interrupting that circuit at an instant when the current has its maximum value, then a large inductive E.M.F. is set up in that circuit which may result in breaking down the insulation between parts of that circuit. The effect arises from the same cause that frequently destroys the insulation of a field magnet of a continuous-current motor or dynamo if the field magnet is suddenly switched off at a moment when the magnet is in a state of excitation.* Broadly speaking, as a practical rule, it should be remembered that long concentric cables having transformers lightly loaded connected to their ends should never be suddenly switched into connection with alternators or switched off, but should always be put into connection with the source of E.M.F. through a regulating resistance or inductance, so arranged as to prevent or check the formation of any oscillations of current other than those due to the natural period of the impressed E.M.F. In the early days of the working of many large alternate-current stations many difficulties were experienced owing to the failure of large transformers and the piercing of long concentric cables which were due to these causes, but experience has now shown how to overcome these difficulties, and to prevent any of these disastrous initial effects. In many cases cables and transformers which suddenly fail when switched into connection with the circuit after being idle for a time, have really been injured at the instant when they were last switched out of connection with the working system owing to the rise of potential that has taken place at the instant when the current was interrupted at a particular instant during its phase. Hence the removal of a cable from a working system at the omnibus bar, or at any intermediate point, must always be effected with the same care as the connection of a cable, and in no case should a long concentric cable, whether connected to transformers or not, be switched on or switched off from the live omnibus bars of the station abruptly. This, of course, does not apply so much to short lengths of a few hundred yards as to long lengths of one or more miles, but it behoves the engineer always to be on his guard against these sources of failure.

The time will not allow me now to develop at any greater length these points, and in closing this brief discussion on the construction and action of transformers there is no need to emphasise the fact that much has perforce been omitted owing to the limits of our time, which a complete treatment would necessarily include. I have endeavoured to direct attention rather to a few principal practical considerations, and to portions of the subject not quite elementary in character, and to assume, as I said at the beginning, that the fundamental principles were already familiar to those present.

Great as has been the progress in 10 years in alternate-current working, no one would be so rash to assume that we have reached the limit of its improvement. The practical perfection of the transformer placed in the hands of electrical engineers an instrument of enormous utility and power for effecting the distribution of electric current. Large as may be our indebtedness to those whose scientific and constructive ingenuity has brought about this advance, we must at the same time remember, with due meed of honour and praise, the pioneering experiments of Paul Jablochkoff and Lucien Gaulard in 1887 and 1882, which, even if not the first suggestions for the employment of the induction coil in electric lighting, certainly forced the attention of engineers to consider closely the value and use of that device, and the service it might be brought to render in the solution of the problems of public and private electric supply.

* For further information on these initial effects see "The Alternate Current Transformers," Fleming, new edition, vol. i., p. 201.

"DYNAMOES." (?)

(See *The Electrician*, July 31, 1896, p. 446, "Load Losses in Dynamoes," by W. M. Mordey).

The innovation comes too late,
The world has learnt the word to spell;
Why fight against the Spelling Fate?
Why shock the readers of the "*El.*"?
Most sounds in spelling don't agree,
But does it matter very much?
Why try to add another "e"?
When dynamos are known as such.
If syntax lies in po-ta-toes,
It's not the same with dynamoes.

The word is known from South to North,
The word is known from East to West;
Where'er an English pen holds forth
The plural is by "s" expressed.
From past decades till time to come,
When men shall store the solar ray;
When dynamos have ceased to hum,
They'll spell it as we do to-day.
That work is slack, one must suppose,
When people gird at dynamose.

If spelling cranks would gain repute,
They'd use the −, not the +;
And find for words the cubest √,
To save our time in writing, thus—
Let c/c, a/c, dy, alt, mo,
Or even signs be used instead,
'Twould knock ·6 off "dynamo,"
And give more time for beer and bed.
Let's hope a fashion comes and grows,
For *shortening* words like dynamows.

J. H. C. B.

LOCOMOTIVES ON HIGHWAYS ACT, 1896.

The following is the text of the new Act to amend the law with respect to the use of locomotives on highways, passed August 14, 1896:

Be it enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:

1.—(1) The enactments mentioned in the schedule to this Act, and any other enactment restricting the use of locomotives on highways and contained in any public general or local and personal Act in force at the passing of this Act, shall not apply to any vehicle propelled by mechanical power if it is under three tons in weight unladen, and is not used for the purpose of drawing more than one vehicle (such vehicle with its locomotive not to exceed in weight unladen four tons), and is so constructed that no smoke or visible vapour is emitted therefrom except from any temporary or accidental cause; and vehicles so exempted, whether locomotives or drawn by locomotives, are in this Act referred to as light locomotives. Provided that (*a*) the council of any county or county borough shall have power to make by-laws preventing or restricting the use of such locomotives upon any bridge within their area, where such council are satisfied that such use would be attended with damage to the bridge or danger to the public; (*b*) a light locomotive shall be deemed to be a carriage within the meaning of any Act of Parliament, whether public, general, or local, and of any rule, regulation, or by-law made under any Act of Parliament, and if used as a carriage of any particular class shall be deemed to be a carriage of that class, and the law relating to carriages of that class shall apply accordingly. (2) In calculating for the purposes of this Act the weight of a vehicle unladen, the weight of any water, fuel, or accumulators, used for the purpose of propulsion, shall not be included.

2. During the period between one hour after sunset and one hour before sunrise, the person in charge of a light locomotive shall carry attached thereto a lamp so constructed and placed as to exhibit a light in accordance with the regulations to be made by the Local Government Board.

3. Every light locomotive shall carry a bell or other instrument capable of giving audible and sufficient warning of the approach or position of the carriage.

4. No light locomotive shall travel along a public highway at a greater speed than 14 miles an hour, or than any less speed that may be prescribed by regulations of the Local Government Board.

5.—The keeping and use of petroleum or any other inflammable liquid or fuel for the purpose of light locomotives shall be subject to regulations made by a Secretary of State, and regulations so made shall have effect notwithstanding anything in the Petroleum Acts, 1871 to 1881.

6.—(1) The Local Government Board may make regulations with respect to the use of light locomotives on highways, and their construction, and the conditions under which they may be used. (2) Regulations under this section may, if the Local Government Board deem it necessary, be of a local nature and limited in their application to a particular area, and may, on the application of any local authority, prohibit or restrict the use of locomotives for purposes of traction in crowded streets, or in other places where such use may be attended with danger to the public. All regulations under this section shall have full effect notwithstanding anything in any other Act, whether general or local, or any by-laws or regulations made thereunder. Every regulation purporting to be made in pursuance of this section shall be forthwith laid before both Houses of Parliament.

7.—A breach of any by-law or regulation made under this Act or of any provision of this Act may, on summary conviction, be punished by a fine not exceeding £10.

8.—(1) On and after January 1 next after the passing of this Act there shall be granted, charged, and paid in Great Britain for every light locomotive, which is liable to duty either as a carriage or as a hackney carriage under Section 4 of the Customs and Inland Revenue Act, 1888, an additional duty of excise at the following rate—namely, if the weight of the locomotive exceeds one ton unladen, but does not exceed two tons unladen, £2. 2s.; if the weight of the locomotive exceeds two tons unladen, £3. 3s. (2) Every such duty shall be paid, together with the duty on the license for the locomotive, as a carriage or a hackney carriage, and shall in England be dealt with in manner directed with respect to duties on local taxation licenses within the meaning of the Local Government Act, 1888; and in Scotland be paid into the Local Taxation (Scotland) Account, and be dealt with as part of the residue within the meaning of Section 2, Subsection (3), of the Local Taxation (Customs and Excise) Act, 1890.

9. The requirements of sub-section (4) of Section 28 of the Highways and Locomotives Amendment Act, 1878, may be from time to time varied by order of the Local Government Board.

10. In the application of this Act to Scotland, a reference to the Secretary for Scotland shall be substituted for a reference to the Local Government Board, a reference to the road authority of any county or burgh for a reference to the council of a county or county borough, and a reference to Sub-section (4) of Section 3 of the Locomotives Amendment (Scotland) Act, 1878, for a reference to Sub-section (4) of Section 28 of the Highways and Locomotives Amendment Act, 1878.

11. In the application of this Act to Ireland a reference to the Local Government Board for Ireland shall be substituted for a reference to the Local Government Board, and a reference to the council of a county shall be construed in an urban sanitary district under the Public Health (Ireland) Act, 1878, as a reference to the urban sanitary authority, and elsewhere as a reference to the grand jury.

12. This Act may be cited as the Locomotives on Highways Act, 1896, and shall come into operation on the expiration of three months from the passing thereof.

THE MANCHESTER REGULATIONS.

Mr. C. H. Wordingham has kindly forwarded to us a copy of the revised regulations as to the supply of electric current in Manchester. The revision was required owing to the departure of using a 200-volt supply in certain districts with a three-wire system having 400 volts between the two outside wires. The rules applying to motor work have also been remodeled. We give the following extracted clauses, which are more or less new, as interesting to central-station engineers:

1. *Pressure of Supply.*—Electricity for purposes other than motive power will be supplied, at the option of the consumer, at the pressure of 100, 200, 300, or 400 volts (except in those districts where the declared pressure is 200 volts, when it will be supplied, at the option of the consumer, at a pressure of 200 or 400 volts). The pressure at which electricity is supplied for motive power will be determined by regulation No. 34. Except by special arrangement not more than 50 amperes may be supplied at 100 volts, nor more than 25 amperes at a pressure of 200 volts from a single pair of service terminals. When more current is to be supplied the lamps or other consuming devices must be divided between the different pairs of the supply mains. If this rule be departed from there is danger that the pressure of the supply will not be so uniform as it should be. The installation must be divided up into circuits of not more than 50 amperes each even when the current exceeds 200 amperes. When the first application is for a supply of current amounting to nearly 50 amperes it is advisable, if there is any possibility of extension, to divide the lamps into two separate circuits, so that additional lamps may be added on either circuit

Digitized by Google

without further breaking up of the street for additional service mains. In the above remarks where the pressure of supply is 200 volts for 50 amperes read 25 amperes.

28. *Starting of Motors.*—All motors must be provided with a switch and starting resistance to be approved by the Corporation's engineer, and to be such that in no case can the current through the motor, when the switch is on the first contact, exceed 10 amperes, or increase by greater steps than 10 amperes at a time as the starting resistance is cut out. This starting switch must be so arranged that it can only be moved very slowly.

29. *Cut-off Switch for Motors.*—The supply to every motor must be controlled by means of an efficient double-pole cut-off switch, placed in such a position as to be easily handled by the person in charge of the motor, and connected so that by its means all pressure can be cut off from the motor itself and from any regulating switch, resistance, or other device in connection therewith.

30. *Cut-outs and Motors.*—An efficient fuse or other automatic cut-out must be provided on each pole so as to efficiently protect the branch circuit to every motor from excess of current; except in the case where motors are supplied at a pressure of 100 volts, two separate cut-outs, and not a double-pole cut-out must be used, and the clear distance between the contact pieces of the cut-out must be not less than 2½in.

32. *Conductors for 400-volt Motors.*—In the case of motors supplied at a pressure of 400 volts the conductors must be enclosed in strong metal casing efficiently connected with earth. The conductors must be insulated in the manner described in Regulation No. 15, except that they must have an insulation resistance of not less than 2,500 megohms per mile when tested after one minute's electrification.

33. *Framework of Motors to be Connected to Earth.* — The magnets, frame, and shaft of all motors must be permanently connected to earth by a copper conductor having a sectional area of not less than 10 square millimetres.

34. *Pressure of Supply to Motors* —Electricity will be supplied to motors at the following pressures: 100 volts for motors absorbing not more than 750 watts; 200 volts for motors absorbing from 750 to 4,000 watts; 400 volts for motors exceeding 4,000 watts.

200-Volt Supply.—In those cases where the declared pressure is 200 volts, the following regulations must be conformed to in addition to those enumerated above:

38. *Two Single-Pole Cut-Outs to be Fixed.*—Two single-pole cut-outs must be fixed instead of one double-pole cut out in all cases.

39 *Length of Break in Cut-Outs.*—The clear distance between the contact pieces of the cut out must be not less than 1in. for fuses intended to melt with currents not exceeding five amperes, and not less than 1½in. for those intended to melt with currents greater than five amperes.

40. *Distribution Boards and Cut-Outs.*—Distribution boards are greatly preferred to separate cut-outs, but where these latter are employed there must be a clear distance between the interior surface of the cover and any portion of the metal work of 1½in.

41. *Ceiling Roses.*—Fuses must on no account be fixed within ceiling roses, but separate cut-outs must be provided unless distribution boards are used. In this latter case, if the lamps are divided into circuits taking not more than three amperes, separate cut-outs need not be fixed for each lamp.

42. *Length in Break in Switches.*—The clear break in all switches must be not less than 1in, and for switches intended to break more than five amperes the clear break must be not less than 1½in.

43. *Key Sockets Not to be Used.*—No combination switch and fitting or key sockets must be employed.

LEGAL INTELLIGENCE.

THE CHARACTER OF LEAD OXIDES.

In the Lord Mayor's Court last week, before Mr. Roxburgh (assistant judge) and a common jury, the case of the Farringdon Works, Limited *v.* the I. E. S. Accumulator Company, Limited, came on.

This was an action to recover £52. 13s. 9d. for goods sold and delivered. The defendants pleaded "never indebted," and counterclaimed for damages, alleging that the plaintiffs contracted to supply them with five tons of oxide of lead, but they only delivered two tons, which were not according to contract, and by reason of which defendants suffered damage. Mr. Crispe appeared for the plaintiffs, and Mr. C. C. Scott for the defendants.

Mr. Crispe, in opening, said the defendant company required, for the purpose of application to their plates, a compound which was called red oxide, and was, apparently, a mixture of an ordinary red lead and litharge. The defendants had a secret in regard to the proportions in which the red lead and the litharge were to be mixed. The plaintiffs had supplied them with red oxide which they obtained from Messrs. Walker, Parker, and Co, the manufacturers, who had been previously instructed by the defendants as to the mode of preparing the compounds. On April 23 defendants sent the plaintiffs an order "for five tons of oxide as before." The two tons of oxide were duly delivered, the invoice price being £35. There was a balance due on a previous account of £17. 13s. 9d., bringing up the amount to £52. 13s. 9d. Credit had been given for £30 paid on May 21, and the balance, £22. 13s. 9d., had not been paid; hence the action. The defendants refused payment on the ground that the oxide supplied was not according to contract. After delivery they telegraphed, "The last two tons of oxide no good; all plates spoiled; send some more at once" The plaintiffs, not being manufacturers, referred to the works, and were told that the oxide complained of was of exactly the same quality as that previously supplied, and had been manufactured precisely in the same way. The plaintiffs could only assume, therefore, that whatever defect there was was due to some fault on the part of the defendants themselves

Mr. Arthur Billyeald, manager to Messrs Walker, Parker, and Co., gave evidence to the effect that the oxide supplied was exactly similar to that previously delivered, and was mixed in accordance with the instructions given by the expert of the defendant company.

Mr. Scott said the defendants declined payment on the ground that the stuff supplied was absolutely useless to them, and counterclaimed for damages by reason of the defective condition of the oxide. The material required was used for accumulators. It was mixed in certain proportions with sulphuric acid, and so formed a cement with which the plates were covered. If the red oxide and litharge were mixed in proper proportions, it would, when treated with diluted sulphuric acid, form a binding cement. The plaintiffs had supplied the defendants with a sample of the stuff which they were prepared to supply, and executed an order to sample, but the second order was not "as before," and did not make a binding material when mixed with sulphuric acid, and a quantity of plates were rendered useless. Defendants consequently declined payment, and counterclaimed for the money which they had lost.

Mr. J. Digby, manager of the defendant company, and **Mr. P. J. Bunn**, their foreman, gave evidence bearing out this statement.

Mr. Crispe called rebutting evidence. His witnesses included **Mr. A. Buckland**, electrical engineer, who said that if care was not taken during the mixing of the oxide with the sulphuric acid to break up any lumps that might be in it, or to get the paste of a proper consistency, the probabilities were that it would not be adhesive.

In the result the jury found for the plaintiffs for the amount claimed.

COMPANIES' MEETINGS AND REPORTS.

CUBA SUBMARINE TELEGRAPH COMPANY, LIMITED.

The half-yearly meeting of this Company was held on Wednesday at the offices in Old Broad-street, Mr. C. W. Parish presiding.

The **Chairman** moved the adoption of the report, which he spoke of as satisfactory. During the past six months the cables had worked well, and the Company had earned a larger sum of money than in any previous half-year of its existence. The gross receipts amounted to £36,186, and the gross expenditure to £9,425, leaving a sum of £26,761, which, added to the balance of £3,719 brought forward from the last account, left £30,481 to the credit of revenue account. The increased traffic and the cost of working the five new stations of the Cienfuegos-Manzanillo cables, which were opened at the commencement of the year, accounted for the increase in the station expenses. The last six months had been a period of anxiety to the Board in consequence of the disturbances in Cuba and the agitation going on among the promoters of fresh cable schemes and new companies. Numerous suggestions were being pressed upon the European Governments to connect their colonies with fresh cables. He thought the necessity for these cables somewhat exaggerated, but the Company should be ready to face any new situation that might arise. Our Government were considering the laying of a cable from Jamaica to Bermuda, but it was a complicated scheme, upon which he had no definite information to give.

The report was adopted.

NORTH STAFFORDSHIRE TRAMWAYS COMPANY, LIMITED.

The ordinary general meeting of this Company was held on Tuesday at the Guildhall Tavern, E.C., Mr. W. J. Carruthers-Wain (the chairman) presiding.

In the course of his speech on the motion for the adoption of the reports and accounts, the **Chairman** said the Act authorising the Company to adopt the new form of traction received the Royal assent only a few days ago, and that had somewhat delayed the negotiations which had been going on for the purpose of applying the electrical system. During the next six months, however, it might be expected that the local authorities would insist upon substantial alterations and improvements being made, and that was one of the reasons why the Board suggested that a considerable sum should be placed to the renewal and reserve fund, so that they might be able to meet the requirements of the local authorities.

The resolution was carried, and dividends were declared for the half-year at the rate of 6 per cent. per annum on the preference shares, and at the rate of 3 per cent. per annum on the ordinary shares.

NEW ZEALAND ELECTRICAL SYNDICATE, LIMITED.

An adjourned ordinary general meeting of this Company was held on Monday at Cannon-street Hotel, E.C., Mr. de Castro presiding.

Before the proceedings commenced, **Mr Huxtable**, on behalf of certain persons, entered a protest against the legality of the

Digitized by Google

meeting, which, he said, had not been properly adjourned. He asserted that Messrs. Boustead and Savory had been elected directors in place of Messrs. de Castro and Grewing, who, however, retained office. The meeting was adjourned by a tacit resolution of the shareholders, although Mr. Lewis and himself protested.

The **Chairman**: Then you have your remedy.

The **Secretary** read the minutes of the original meeting, stating that it was adjourned in consequence of there not being a quorum present, and the chairman proceeded to sign them, in spite of a protest from Mr. Huxtable, who said he had the opinion of Mr. Cozens-Hardy, Q.C., to the effect that the election of Messrs. Boustead and Savory to the board was in order.

The **Chairman** said that the directors had been unable to obtain any information from the receiver and manager of the company, who was in possession of all the Company's property and books of account, as to the position of the Company. They were, therefore, unable to present any accounts or any balance-sheet to the shareholders. Under these circumstances both the directors were anxious to retire from the Board, and tendered their resignations to the shareholders; but as the Company might be placed in a very difficult position if they vacated their seats without providing for the election of their successors, they were willing to remain in office until new directors had been elected by some properly-constituted meeting of the shareholders. The Chairman then declared the meeting closed.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Merida (Spain).—The Local Authorities of Merida in the province of Badajoz want tenders by August 25 for the electric lighting of the town.

Nava del Rey (Spain).—The Municipality are open to receive tenders up to August 28 for the electric lighting of Nava del Rey for a period of 20 years.

Paris.—Tenders are wanted by September 8 for the supply of magneto-electric calls for the Departments of Posts and Telegraphs, rue de Grenelle 103, Paris.

Ghent.—Tenders are wanted by M. le Percepteur des Postes, Grand Centre, for telegraphic maintenance work. The date is August 28, and the amount small.

Dantzig.—Tenders are wanted for the supply of incandescent lamps and carbons. Particulars for 75 pf. (9d.) from the Konigliche Direction der Gewehrfabrik, Dantzig.

Dortmund (Germany).—The Municipal Authorities of Dortmund want tenders by September 1 for engines, boilers, and dynamos for the electric lighting of the town.

Spa (Belgium)—The Burgomaster and Echevins of Spa invite propositions for undertaking the public lighting, either electrically or by acetylene. The date fixed is September 15. No further information is given in the official advertisement.

Copenhagen.—Tenders are wanted for the supply of 20,000 incandescent electric lamps. Application should be made to Directeuren for Kjöbenhavens Belysningsväsen, Gothersgade, 30, Copenhagen, and tenders must be in by August 22.

The Hague.—Tenders are wanted by August 24 for the supply to the Dutch Government of iron telegraph posts, galvanised iron wire (telegraphic, insulator pins, etc. Application should be made to the Dutch Colonial Ministry at the Hague.

St. Pancras.—Tenders are wanted for the supply and erection of 80 arc lamp columns about 19ft. high, for the St. Pancras Vestry. Particulars are obtainable at the Vestry's Electric Department Offices, 57, Pratt-street, Camden Town, N.W., and tenders must be in by August 24.

Villefranche-Lauragais (France).—The Municipality of Villefranche-Lauragais (Haute-Garonne) have invited competitive plans for a public water supply and electric lighting. Prizes of 1,000fr., 500fr., and 200fr. are offered, under the usual conditions, and schemes must be sent to the Mairie by October 10.

Cork.—The Corporation of Cork invite tenders for the transfer of their provisional order for electric lighting. The working of this will probably also include the supply of current to an electric tramway. Particulars can be obtained (on the deposit of one guinea) from the Town Clerk, Municipal Buildings, Cork.

Paris.—There is to be a limited competition for the supply of cables for the electric lighting of the Avenue de l'Opéra. The date is August 27. There is also for tender the work of installing the electric light at the College Chaptal, 49, Boulevard de Batignolles. Application must be made immediately to the Hotel de Ville.

Cologne.—Tenders are required by the Municipal Authorities for the construction and working of electric tramways in the city of Cologne to an aggregate length of 20·3 kilometres (12½ miles). Specifications, plans, and particulars are obtainable for 10 marks (10s.) from der Registrateur B, des Oberbürgermeisteramt, Köln, Germany, and tenders must be in by November 6.

Madras.—Tenders are invited for the lighting by electricity of Government House, Madras, including the banqueting-hall and aide-de-camps' bungalow, and also for the lighting of Government House, Guindy, including the military secretary's bungalow. For particulars application must be made to the consulting architect to the Government, Chepank, Madras. Tenders will be opened on November 11, 1896.

Voghera (Italy).—In view of the expiration of their contract with the local gas company in 1898, the municipal authorities of Voghera are desirous of receiving during the present year propositions for the lighting of the town either by the electric light or a mixed system of gas and electricity. The population is 16,000. Application should be made to L'Administrazione Comunale, Voghera, who will give all particulars necessary.

Mayaguez (Puerto Rico).—The Secretary of State for Foreign Affairs has been informed by H.M. Ambassador at Madrid that the Spanish Government have invited tenders for the construction and working of a telephone system in Mayagüez, Puerto Rico. The date fixed for the consideration of tenders is October 8, and such particulars as have been received may be inspected at the Commercial Department of the Foreign Office between the hours of 11 and 6 daily.

Dewsbury.—Tenders are invited by the Governors for the wiring and fitting of the Dewsbury and District Technical School. Copies of specifications may be obtained from the Secretary on payment of £1. 1s., which will be refunded on return of same, accompanied by a bona fide tender. Plans may be seen at the office of the Secretary, from whom any further information can be obtained. Sealed tenders must be sent to Mr. P. F. Lee, secretary, endorsed "Electric Lighting," by 22nd inst.

Southampton.—The Harbour Board invite tenders for the construction and erection of four electric cranes and accessories, and also for alterations to a gantry of an existing crane, on the Town Quay, Southampton. Specification, with two general drawings attached, may be obtained on and after 20th inst. from Mr. A. H Skelton, clerk, Town Quay, Southampton, upon payment of £3. 3s., which will not be returned, and further detailed plans may be seen at the office of the electrical engineer, Mr. J. G. W. Aldridge, 9, Victoria-street, Westminster, S.W. Sealed tenders, marked "Tenders for Electric Cranes," should be sent to the clerk by August 31.

Jassy.—The Mayoralty of the Town of Jassy (Roumania) has given notice that on August 23, 1896, old style (by our reckoning September 4), tenders will be received, for the second time, in the hall of the Municipal Council, for "the installation of a frigorific hall, electric light, and various accessories requisite for new public slaughter-houses. Offers must be in accordance with the specification, the conditions of contract, the special conditions, and the plans deposited in the offices of the director of the slaughter-house works, where particulars may be obtained." Tenders are to be enclosed in sealed envelopes, marked "Offre pour l'installation de la Hall Frigorifique," and senders of tenders must abide by articles 68-79 of the Roumanian Public Accounts Act. All tenders and supplementary documents must be in either the Roumanian or French language.

Cadiz.—The Secretary of State for Foreign Affairs has received dispatches from her Majesty's Consul at Cadiz, stating that preliminary tenders for a supply of electric lighting apparatus for the illumination, on the most approved modern plan, of private houses, etc., in the town of Cadiz are invited by the "Sociedad Co-operativa Gaditana de Fabricacion de Gas." It appears that the tenders should be sent in by September 15 to the above-named company, whose offices are San José, 25, 27, and 29, Cadiz. Firms wishing to obtain the contract for the supply of plant are advised by the Consul to send representatives to treat personally with the company. Such additional particulars as have reached her Majesty's Government on the subject may be viewed at the Commercial Department of the Foreign Office, any day between the hours of 11 a.m. and 6 p.m.

Bath.—The Corporation invite tenders for the supply and erection of the following plant:—Section A: Boiler and fittings, feed pump, etc. Section B: Steam alternators, oil-filter, fittings, etc., steam, exhaust, feed, blow-off, and sundry pipes, valves, etc. Section C: Mains. Section D: Crane. Section E: Arc lamps and posts. Tenderers are at liberty to tender for either section, but not for part of a section. The ground plan of plant and specification, with terms and conditions of tender and contract, may be obtained at the office of Mr. Robert Hammond, the consulting engineer, Ormond House, Great Trinity-lane, E.C., on and after the 13th inst., on payment of £2. 2s., which will be returned on receipt of a bona fide tender. Sealed tenders, marked "Tender for Electric Lighting," must be addressed to Mr. F. H. Moger, clerk, 3, Wood-street, Bath, and delivered by the 31st inst.

RESULTS OF TENDERS.

Walsall.—For providing and fixing a water-tube boiler at the electricity station, for the Town Council, the tender of Messrs. Babcock and Wilcox, at £486. 10s., has been accepted.

Southend.—Messrs. Lowe and Hoad's tender of £15. 15s. for fixing a telephone between the medical officer's residence and the sanitorium has been recommended for acceptance by the Town Council.

Tournai.—The lowest tender for generating station buildings at the Tournai Asylum on August 8 was that of Messrs. L. Bariseau at 10,977fr. The estimate was 13,300fr., and all the tenders were below this.

Brussels.—The contract for the construction, maintenance, and working of an electric tramway from the Rue Gerard to the Bois de la Cambre, for the local authorities, has been placed with the Tramways Bruxellois.

Whitehaven.—The Town Council have accepted the tender of the Lowca Engineering Company for the purchase of the donkey engine at the electric lighting station. One other firm tendered. The price is not given.

Digitized by Google

BUSINESS NOTES.

Newbury.—The dynamo room at Dean Wood has been destroyed by fire.

Llanelly.—The electric lighting question has been discussed and adjourned.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,744.

Santiago (Chile).—The Municipal Council have been considering the conditions on which tenders should be invited for a scheme of electric lighting.

Bury St. Edmunds.—The Ratepayers' Association have held a demonstration against the Town Council adopting an electric lighting scheme.

West India and Panama Telegraph Company.—For the half-month ended August 15 the receipts were £1,704, as against £1,660 for the corresponding period of 1895.

A'derley Edge.—After some discussion, the Urban District Council have given the chairman power to complete the transfer to the Council of the electric lighting order.

Colwall (Hereford).—The Parish Council have appointed a committee "to make enquiries and report as to having a telephone exchange at Colwall." The population is 1,400.

Monte Video.—A project has been presented to the Monte Video (Uruguay) Municipality for an electric tramway from that city to Colon along the new high road lately constructed.

Market Deeping.—The local Council have refused the offer of the gas company to light the town with gas from September 1 to April 1 for £130, but what, if any, other means of illumination is contemplated is not stated.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending August 16 amounted to £1,375, as compared with £1,374 in the corresponding week of the previous year, being an increase of £1.

Dover.—On the occasion of the installation of the Marquis of Salisbury as Lord Warden of the Cinque Ports the street decorations were very elaborate, and the sea front was lined out round the entire bay with electric lamps.

Motor Car Syndicate of Australia, Limited.—This is a Company which has been registered, with a capital of £5,000 in £1 shares, to manufacture, sell, and deal in "auto-motorcars," carriages, tramcars, cycles, ships, etc.

Bristol Tramways and Carriage Company, Limited.—The traffic returns for the week ending August 14 were £2,376. 17s. 7d., compared with £1,938. 9s. 1d. for the corresponding period of last year, being an increase of £438. 8s. 6d.

Dundee.—It has been explained, with reference to the staffing of the electrical department, that the increase in the subordinate staff resolved on by the committee only means that a switcher at a wage of 30s. a week, and another man at 15s is to be added.

Bedford.—The St. Paul's Wesleyan Chapel has been reopened. The old gas brackets have given way to the electric light, the installation of which was entrusted to Messrs. Kilpin and Bilson. This is the first place of worship in Bedford to utilise the light.

Kirkby Lonsdale.—Mr. A. M. Harris has submitted to the Urban District Council an estimate for an electric lighting supply, but as the Council is treating with the gasworks for the purchase of their undertaking it is not probable that much will come of it.

The Brush Company.—Notice has been given that the transfer books of the first debenture stock of the Brush Electrical Engineering Company, Limited, will, in view of interest payable on September 1, 1896, be closed from August 19, 1896, to September 1, 1896, both inclusive.

City and South London Railway.—The returns for the week ended August 16 were £1,110, compared with £924 for the corresponding period of last year, being an increase of £186. The total receipts for the half-year 1896 were £6,529, compared with £6,008 last year, being an increase of £521.

Motors, Limited.—This is the name of a company registered by Thomas Durant, 5, Guildhall chambers, E.C., with a capital of £5,000 in £1 shares, to enter into an agreement with S. L. Phillips and to carry on business as electricians, mechanical engineers, etc. The office is at 12, Camomile street, E.C.

River Plate Electric Light and Traction Company, Limited.—The River Plate Trust, Loan, and Agency Company notify that the scrip of the issue of £125,000 5 per cent. first debenture stock is now ready, and can be had at their offices, 52, Moorgate-street, E.C., in exchange for the allotment letters duly endorsed.

Bolton.—At a meeting of the Gas and Electricity Committee it was reported that the receipts from electricity consumption for the past year amounted to £1 689. 2s. 8d., as against £694. 14s. 8d. for last year. There were now 155 consumers of electricity as against 70 last year, and there are applications from 13 new customers

Halstead (Essex).—The surveyor reported to the Urban District Council that Messrs. Crompton's agent had visited the town on the subject of an arrangement for introducing the electric light, and would send in his report in due course. Mr. Carter remarked that the agent thought the matter was well received by the people.

Manlove, Alliott, and Co, Limited.—This is a new Company, registered with a capital of £150,000 in £10 shares, to carry into effect an agreement with Manlove, Alliott, and Co., Limited (the old company, incorporated in 1888), and the liquidator thereof, for the acquisition, as a going concern, of the business, assets, and liabilities.

Inverness.—At a meeting of the Town Council Provost MacBean moved that the Council oppose the application by a London electric lighting company for a provisional order for the electric lighting of Inverness as the Council, as Gas Commissioners, were quite capable of supplying any artificial light, whether electric or other. The motion was adopted.

Appointments Vacant.—The Hammersmith Vestry want a resident electrical engineer. The salary is to be £200 a year, and £250 when the works are finished and running. Application should be made to the Vestry Clerk, at 57, Fulham Palace-road.—The Lancaster Corporation require a dynamo and switchboard attendant at 25s. a week. Application is to be made to the Town Clerk.

Withington.—At the Urban District Council the minutes of the General Purposes Committee, which were approved, stated that they had had under consideration the adoption of electric lighting, and that it had been decided to send a postcard to the owners and occupiers of all houses of a rental of £30 and upwards asking whether they were in favour of the project; also that a report on the whole question would be prepared and laid before the Council.

Croydon.—The Chairman of the Tramways Company, Mr. C. Wain, speaking at the general meeting on the subject of electric traction, said although he believed in electricity, gas, oil, and many other things which were going to be the motors of the future, he was of the opinion that there was a good deal left in the horse yet. For the present they must be content to go along with horse-power.

Douglas (Isle of Man).—At the Town Council a proposal to enter into a contract for the adoption for five years of incandescent gas lighting for the whole town was submitted, and was met by an amendment that the matter be deferred with a view to considering the question of lighting the town by electricity. It was decided ultimately that the subject be reconsidered before any system was selected.

New Addresses.—Mr. F. J. Warden Stevens informs us that he has found it necessary to remove from Martin's-chambers, Cannon-street, E.C., to larger offices at Connaught-mansions, 34, Victoria-street, Westminster, S.W. His country offices will remain at Town Hall-chambers, Guildford.—Mr. J. S. Cunnington has removed from John-street, Adelphi, to larger premises at 18, Cecil-court, Charing Cross-road, W.C.

Radcliffe.—The minutes of the meeting of the Electric Lighting Sub-Committee contained a resolution recommending the Electric Lighting Committee to grant to the clerk an honorarium of £20 in consideration of the extra services rendered by him in obtaining the provisional order. There was some discussion on this in the full Council, and the matter was left over until it had been reported to the Electric Lighting Committee.

Ripon.—At Studley Royal, the seat of the Marquis of Ripon, without waiting for other people, or heeding the good reasons and good taste which are understood to have prevented any such display elsewhere at present, they have begun the celebration of the sixtieth year of the present reign. The only point of interest so far as we are concerned is, however, that, as part of the celebration, at night the town was illuminated by electricity.

Pulleys and Shafts.—We have to acknowledge the receipt from Messrs. J. Bagshaw and Sons, Limited, of Batley, of their rules and tables for engineers and architects. The book is, of course, a catalogue and price-list of Messrs. Bagshaw's manufactures, but it contains a large amount of information on the subject of the transmission of power by shafting and belts, and there are also tables of safe loads for iron girders, weights of bar iron, etc.

The Electrical Trades Union.—We are requested by Mr. J. E. Sims, the organising secretary of the above union, to announce that a meeting will be held on Monday, 24th inst., at 8.30 p.m. This will be addressed by Mr. Sims, who will explain the object of the trade combination and the benefits expected to accrue to the members. The meeting will be held at the Club and Institute Buildings, Clerkenwell-road, E.C., and all electrical workmen are invited.

Anglo-French Motor Carriage Company, Limited. — This Company has been registered, with a capital of £300,000 in £1 shares, to adopt an agreement with E. Rogers and to carry on business as manufacturers of and dealers in motors and motorcars, etc., and as manufacturers of steam, gas, oil, and electric engines, motors and dynamos, and builders of launches; as mechanical and electrical engineers, and to construct tram roads. The registered office is 58, Coleman-street, E C.

Metropolitan Electric Supply.—The *Financial Times* says it has received bitter complaints by private customers of the Metropolitan Electric Supply Company because the company has reduced the price of lighting to shops and business premises owing to the competition of the Charing Cross and Strand Electricity Supply Company, while it has made no similar concession to the occupiers of dwelling-houses. That somebody else is being benefited does not seem very substantial ground of complaint.

Central London Railway.—At the London Sheriffs' Court, on the compensation claim coming on of Mr. Robert William Clarke, an ironmonger at Bayswater, who sought to recover from the Central London Railway Company £12,500 as compensation for

Digitized by Google

the compulsory acquirement of his premises, situate at 1, Coburg-road, and 1, Queen's-road, Bayswater, for the purposes of the construction of their new line, a consultation between counsel ensued, with the result that it was agreed to enter a verdict for the claimant for £6,500.

City of London Electric Lighting Company, Limited.—The revenue return for the quarter ended June shows an increase of £4,718, the gross returns from public lighting being £3,189, against £3,202 last year, and from private lighting £16,564, against £12,283, and from other sources (estimated) £650, against £200. The equivalent of 8-c.p. lamps connected on June 24, 1896, was 215,559, being an increase during the quarter of 8,291. The corresponding figures for the same quarter in the previous year were 159,250 and 10,656.

Brighton.—The large sea-going car for the Rottingdean Electric Railway is now erected, and has been tried. As soon as the necessary connections were made, and the current from Volk's Electric Railway turned on, the car at once started, the control over its movements being absolute. The remainder of the overhead wire is now being erected, and after inspection by the Board of Trade the line will be opened for traffic. Very little remains to be done, the machinery at Rottingdean Pier is fixed, and nearly ready to start. The car is standing close to Paston-place jetty, and can be examined there.

St. George's, Hanover-square (London).—The Electric Lighting Committee have considered a letter from St. James's (Westminster) stating that that Vestry proposed erecting five electric light lamps, at a cost of about £38 each, in the centre of the roadway of Piccadilly and St. James's-street, and expressing a hope that, as a portion of the streets to be lighted is in St. George's, the Vestry would consent to contribute one half of the cost. Mr. Macdonald moved that they assent to the request of the St. James's Vestry. Mr. Burch objected; St. George's was to find the money, but St. James's would control it, and the motion was rejected by 15 votes to 7.

Taunton.—The electrical engineer (Mr. Harold W. Couzens, A I.E.E) has presented his quarterly report, as follows: "I have the honour to report that during the past quarter there has been a satisfactory increase in our lamp connection—92 lamps (of 16 c.p) having been installed and a further 84 applied for. We have been busily engaged with the many and varying details incident to the changing over the remainder of our supply to the underground conductors; these will be very shortly completed, and we shall then remove the overhead wires at once. The machinery, plant, and apparatus has been maintained at its thorough state of efficiency."

Boston (Lincolnshire).—At the Town Council meeting Mr. Pooles asked whether any report had been received from the Paving and Lighting Committee with reference to the electric light. The Mayor said the committee had appointed a sub-committee to gather information on the subject. Mr. Waddington hoped sufficient time would be given to enable the shareholders in the gas company to sell out, and Alderman Bedford said the matter would require a great deal of consideration, and he hoped the committee would be exceedingly careful in dealing with it. He was not a shareholder in the gas company, and therefore he was unprejudiced in the matter.

Warminster.—Mr. Mark Hlils' reply to the Town Council's offer in reference to the electric lighting account, reiterates his claim, and adds: "I lost at least £100 by it (the lighting), and can prove it; but in order to meet you I offer to take £50, without prejudice, in settlement of my claim against you, which was a reasonable one. I shall not allow the cable to be removed until my claim has been paid, and unless that is done at once, I shall instruct Messrs. Cruttwell and Daniell to issue a writ for my out-of-pocket expenses, which are £100." The difficulty appears to have arisen from individual members of the Council making verbal representations as to what that body would be willing to do. No resolution was come to.

Ealing.—The surveyor has reported that the number of lamps, including 600 8 c.p. lamps at Gunnersbury, was now 8,771 and by the end of the month would be 9,000. Of this number 7,754 were actually connected with the mains upon the 5,000 lamp installation. He hoped that all the present difficulties would speedily be overcome. One of the two new engines had been in working order for the past three days, and it had turned out as satisfactorily as could be expected. The engine power at the works was now in excess of the boiler power, and the Electric Lighting Committee accordingly recommended the purchase of a new boiler at a cost of £500. This was unanimously agreed to by the Urban District Council.

Hunstanton.—At a meeting of the Urban District Council Mr. Beeton proposed the motion of which he had given notice, to take into consideration the question of an electric light supply within the limits of the district. He merely wished to ventilate the subject and then suggest its postponement to a future meeting. The electric light would be cheaper, and would ease the gas-works, as he thought the plant of the company was hardly sufficient for the wants of the town in the season. The engine they would use for the light would also be available for sewerage, and for pumping sea water for use in watering roads. Several members agreed that the supply of gas for the past few weeks had been insufficient, but the subject was dropped without any resolution being arrived at.

Liverpool.—Mr. Holme, electrical engineer, having prepared a report on the question of the proposed reduction of charges for electric lighting, after this had been read and discussed the Lighting Committee decided to recommend the Council to sanction the following reductions: meter rents from 2s. to 1s. per month, and in place of the existing uniform charge of 7½d. per unit that a scale as follows be adopted on and after October 1—for each unit up to 1,000 per month, 7d. per unit; for each unit in excess of 1,000 per month, 4d.; that the charge for electrical energy for heating, cooking, etc., when supplied through a separate meter, be reduced from 5d. to 4d per unit; and that consumers occupying two or more places of business be allowed to have them included as one item.

Greenwich.—At the general meeting of the London, Deptford, and Greenwich Tramways Company Mr. W. J. Carruthers-Wain (the chairman) said as to the possibilities of the future as regards traction, though he went all over America for the third time last autumn, and saw one or two systems supposed to be good for crowded thoroughfares and heavy traffic, he did not really see—subject, of course, to the improvements that had been made since—anything that would be suitable for the Greenwich line. They had tried the Connolly motor, the oil engine; had tried compressed gas as well, and had also given consideration to the question of the new motor, the company to work which was launched the other day—namely, the Zurich gas motor—on some of our tramways for some little time. They must wait a little while longer before doing anything.

Eccles (Lancs.).—The Local Government Board have declined to sanction borrowing powers for £20,000 to enable the Town Council to carry out its electric lighting scheme. It will be remembered that Mr. G. W. Willcocks, M.I.C.E., held an enquiry at the Town Hall in June, when considerable opposition was raised to the application by some members of the Council and the Eccles Property Owners' and Ratepayers' Associations. The enquiry lasted two days, and at the hearing the town clerk informed the Commissioner that the Board of Trade had agreed to extend the provisional order for 12 months from June 12. The scheme has been the subject also of much opposition at the Council meetings, and was only carried by the casting vote of the Mayor. Since then two members have been elected to oppose the scheme, so that there is a majority of dissentients now on the Council.

Portsmouth.—The Finance Committee recommended that proceedings should be instituted by the Town Council against the Portsea Island Gaslight Company for having supplied the borough with gas of less illuminating power and less purity than prescribed. Mr. Scarrott moved that the clause be referred back, saying that the prosecution was suggested by the jealousy of the Electric Light Committee. During the discussion the Town Clerk said the gas company disputed the accuracy of the test. The amendment was, however, lost, and the prosecution ordered. The Electric Light Committee recommended that motors and ovens be let on hire to consumers at 15 per cent. on the cost price; also that the Baths and Wash-houses Committee should be charged for the current at the rate of 2½d. per unit during the day only, and these recommendations were adopted.

Thorne (Yorks).—At the Board of Guardians the Clerk stated that he had had a visit from a representative of the National Telephone Company, the company being desirous of fixing a wire to the chimney of the Thorne Union Workhouse, and agreeing to pay 1s. per year acknowledgment. Mr. Standring thought it would be a favourable opportunity for making terms for the clerk to have a telephone at a reasonable cost. Mr. J. J. S. Clarke said that if the wire were affixed to the chimney it would be a nuisance. When the wire was repaired the workmen would disturb the tiles on the building, which would allow water to percolate through the roofs. At any rate, that had been his experience. Mr. Cooper concurred, adding that such had really been the case at Hatfield. Mr. Clarke pointed out that the nuisance was rendered greater by the continuous humming. Mr. Standring suggested that probably the requirements of the Telephone Company would be met if they were allowed to fix a post, and this was agreed to.

Blackpool.—The Town Council will proceed at once with the construction of tramways from the south end of Cookson-street, along Raikes-road, Whitegate-lane, and Cowgap-lane to Lytham-road. At the next session of Parliament, the town clerk is authorised to promote the provisional order for tramway extensions to complete the entire circle from Queen-street, along Parker-street, Abingdon-street, to the south end of Cookson-street. This will complete the scheme, and every part of the town will then be brought into close connection with every other, and a girdle of tramways will encircle the town from Talbot square round by Marton and the Promenade back again to Talbot-square. For this work the overhead system is to be adopted, instead of the conduit system now in use on the Promenade. As to the electric lighting, it is stated that the new engineer, Mr. Quinn, is asking for nearly £10,000, chiefly for laying new mains, and that an alteration is contemplated in the system of supply.

Yarmouth.—The surveyor reported to the Town Council that seven more customers had been secured for 655 lamps, the total now being 184 for 9,020 lamps. The income in July amounted to £150. 6s. 8d., while the cost of production was £136. 9s. 11d., leaving a balance of £13. 16s. 9d. to meet capital and interest charges of £130 per month. A memorial was read from the secretaries of seven places of worship asking that a reduction should be made in the charge for the supply of current to their buildings, pointing out that such supply would largely be required during the time that a light load was being sent out from the works. The Electric Lighting Committee decided that the application should stand over until the undertaking had become more remunerative. An amendment was moved that the last paragraph be referred back, on the ground that it would be a good thing to get the light into the churches, where it would be

Digitized by Google

chiefly used on Sunday evenings. Mr. Martins said the objection was that the churches would require the light on weekday evenings as well, when the machinery was being worked at high pressure, but the amendment was agreed to.

Dewsbury.—At the Lighting Committee the electrician reported that 1,534 units of electric energy had been discharged (this is apparently the Dewsbury form of report) during the fortnight ended July 4, against 584 units for the corresponding period last year. The gas manager also reported the distribution of 3 692 000 cubic feet of gas for the same period, against 3 846,500 last year. It was resolved that the borough accountant transfer £1,000 from the electric lighting account to the gasworks capital account as the purchase price for the site of the electric lighting works. At a subsequent meeting the electrician reported that the electric energy discharged during the fortnight ended July 18 was 1,658 units, against 562 last year. The gas manager reported that for the same period 3,866,500 cubic feet of gas had been distributed, against 4,076 000 last year. The electrician was instructed to get further information with respect to the supply of cable for the extension of the electric mains to the technical school, and that the chairman, vice-chairman, and Councillors Oldroyd and Phillips should be empowered to accept any tender they may consider desirable. The report of the committee was adopted by the Town Council.

Hull.—It will be remembered that the Town Council by a small majority rejected the recommendation of the Electric Lighting Committee for a new generating station. At a new meeting of the committee applications for the supply of electric light were received from Messrs. Hammond and Co , Osborne-street, and Mr. Robinson, Charlotte-street. Dr. Kessen and Alderman Hall expressed themselves favorable to these firms being supplied with the light, though in the case of Messrs. Hammond it would mean an expenditure of £60 for additional mains, and of £250 for a main to serve Mr. Robinson. Mr. Crook objected to such items of expenditure, contending that the committee should comprehensively light the town with electricity. The engineer explained that there were now 23,414 lamps connected to the present station, and the maximum output was between 19,000 and 20,000 lamps. Mr. Parrott said this strengthened the case of the committee for an extension, because from the engineer's figures they had already exceeded their maximum power of supply. It was resolved to inform the applicants that the committee regretted that owing to the demand upon the present station they were unable to comply with the request. An application was also received from the manager of the Grosvenor Hotel asking for a supply. Ultimately Alderman Hall moved that the committee re-affirm their conviction that it was necessary to provide additional generating plant. Mr. Hanger seconded the motion, which was carried. It was then agreed on the motion of Alderman Hall, seconded by Mr. Hanger, to engage a consulting engineer, to advise and report on the whole matter.

Southampton.—In reference to the purchase of land at the electric lighting station, the town clerk submitted letters to the committee from Messrs. Kincaid, Waller, and Manville, the consulting electrical engineers of the Corporation, asking whether, in completing the contract drawings, they were right in assuming that the Corporation would be able to obtain the additional land to the north side of the site. The town clerk also submitted an offer in writing from the owners of the land to sell to the Corporation the whole of the land at the price of £5,890 It was resolved that the town clerk be authorised to offer a price not exceeding £5,300. At a subsequent meeting the town clerk reported that this was accepted, and the committee recommended the Council to apply to the Local Government Board for sanction to borrow the sum of £5 300, in addition to the sum of £50 000, in connection with the electric lighting undertaking. Alderman Bone, moved the adoption of the committee's report. Mr McDonnell said he was surprised that the Council were asked to vote £5,300 in respect of the electric lighting undertaking so soon, as they had allowed a large margin in granting the main purchase money, which they were told at the time was sufficient to provide for all emergencies. The committee's report was adopted. There was a long discussion on the Works and Fire Brigade Committee's report with reference to the recent fire, which stated among other matters that the committee were satisfied from the evidence that the telephonic communication was out of order, but that had the telephone been in order, the evidence proved there was no person in charge of the police station at Portswood to answer the telephone after 12 o'clock at night. Ultimately the committee's report was adopted.

Moss Side (Manchester).—At the meeting of the Urban District Council held recently, the clerk reported that a letter had been received from the Gas and Electric Lighting Committee of the Manchester Corporation, suggesting a conference of the Stretford, Moss Side, Withington, and Levenshulme Councils respecting the extension of the Corporation electric current in these districts. A deputation was appointed to attend the conference on behalf of the Council. It was also reported that a deputation had waited upon the General Purposes Committee on behalf of the South Manchester Electric Supply, Limited Mr. Clirehugh, on behalf of the deputation, expressed an opinion that the cost of the first instalment of cabling in the district would be about £5,000. The company would offer the Council a wholesale supply of current at a charge of 4d. per unit, leaving the Council to supply customers and collect accounts. The usual charge by the company was 7d. per unit. The Council might at any time acquire the undertaking in their district by giving six months' notice, subject to certain other conditions. The district would comprise Moss Side, Stretford, Withington, Levenshulme, and Heaton Norris, with a central supply station near the crematorium at Withington. It was further reported that the General Purposes Committee had received a deputation from a syndicate for supplying electricity for lighting or for motive power. The deputation explained the proposal of the company. They suggested a scheme of tram haulage in connection with the scheme for laying suburban lines from Peel Causeway through Brooklands and Sale to Stretford, and remarked that the lines might be continued along Seymour-grove, Old Trafford, branching off at West Point to Chorlton-cum-Hardy; also to Brooks's Bar, along Raby-street and Moss-lane East, Wilmslow-road, and Dickenson-road to Longsight, with a branch at Stretford along Edge-lane to Chorlton-cum-Hardy, and so forward past the Manchester Cemetery, Burton-road, Lapwing-lane, and on through Heaton Mersey to Stockport. The deputation was informed that the Council would give early and earnest consideration to the suggestion made on behalf of the company.

Canterbury.—The Lighting Committee have reported that Mr. R. Hammond, the electrical engineer, had attended and submitted final plans and estimates, etc , of the electric lighting works and dust destructor. The committee recommended that they should be adopted, and that the engineer be authorised to advertise for tenders. The committee recommended that a sum of £1. 1s. per day be allowed as travelling expenses to the engineer for his visits to the city, and that second-class railway fare and expenses be allowed his assistant. In the Town Council Alderman Cross asked if it had been finally decided that the dust destructor be placed on the site at the Miller's Field. He thought before giving orders for tenders to be advertised for they should come to an understanding whether the Council had quite decided to have the destructor on that site, as he was under the impression the majority were against it. He should also like to suggest that first-class fare and no expenses be allowed the engineer's assistant. After a good deal of discussion an amendment was carried rejecting the dust destructor, and finally the whole question became mixed up with the sewage farm and the drainage system, so that the Town Clerk said he did not know what to do. The plans were prepared and everything got ready for the reception of tenders, and now they had done something which would prevent the tenders being asked for The plans and forms of tender had already been drawn up—one for the electric lighting station only, and the other including the destructor—and if they adhered to the resolution now passed they would have to alter the whole thing. He should be really ashamed to write to the engineer. He appealed to the Council whether the course recommended should not go on. They could afterwards accept the tenders or not as they thought fit. Ultimately, by way of getting matters in order and getting rid of conflicting resolutions, the town clerk suggested that the whole thing should be referred back to a special meeting of the Council, and, after further discussion, this course was agreed upon, it being also resolved that no minutes be taken of that day's discussion.

Morley.—The town clerk has reported to the Town Council that he has received the formal license granted by the Board of Trade under the Electric Lighting Act authorising the Corporation to undertake the supply of electric light. Alderman Stockdale moved and Councillor Craven seconded the adoption of the following report of the Electric Lighting Committee: "The committee, at a meeting on the 13th ult., had an interview with Mr. Hammond and discussed various additions and alterations which the increased experience derived from new works had rendered desirable since his first report was given three years ago. After fully considering the matter, the committee recommended (1) that the alterations and additions be approved, and that Mr. Hammond be requested to amend his original report and estimate in accordance therewith; (2) that as it is found to be impracticable to have the scheme generally available by November 1 next, the contracts be advertised in sections for the various kinds of work, as may be approved by the committee, the underground work to be advertised and let at the earliest moment; (3) that in consequence of the present condition of Queen-street, the borough surveyor be instructed at the earliest possible moment to have iron pipes fixed under all street crossings, in positions to be indicated by Mr. Hammond, to enable the paving to be proceeded with; (4) that the committee be empowered to make such temporary arrangements for augmenting the Town Hall supply as will enable pressing cases to be dealt with as they arise; (5) that Mr. Hammond's remuneration be fixed at 5 per cent. on all contracts which may be actually carried out, in addition to travelling expenses, and the quantity surveyor's fees at 2½ per cent. on such contracts, but this is not to impose any obligation on the Council to proceed with any work. The premium of £100 is to be merged in the commission. This is not to include the clerk of works." Alderman Dixon moved an amendment, which Councillor Armitage seconded, that clause number 5 be altered by providing that Mr. Hammond be not allowed travelling expenses, and that the commission to him and the quantity surveyor be limited to 5 per cent. to Mr. Hammond, and with this alteration the report was adopted.

Hammersmith.—We have received the tenth annual report of the Hammersmith Vestry. This gives a full account of the work of the Vestry, and its appearance serves as a suitable occasion for summing up the progress made towards the adoption of the electric light in that parish and the method of procedure. On April, 1895, the Electric Lighting Committee reported on the various sites available for a generating station, and recommended the Vestry to treat for the purchase of two pieces of land abutting upon Fulham Palace road. The report was approved, and the purchase was subsequently completed for £7,200. The next report is dated May 29, and is to the effect that having appointed a sub-

Digitized by Google

committee, who have viewed the electric lighting installations at Chelsea, Ealing, St. Pancras, and Portsmouth, and carefully considered the information gained respecting the various systems in use at those and other places, the committee could not then advise the adoption of the report of Messrs. Williams and King. They recommended the Vestry to advertise for complete schemes and tenders for boilers, machinery, mains, etc., necessary to carry out the work included in the compulsory area, and when such tenders and schemes were received, the Vestry should proceed to consult one or more engineers to advise thereon. This recommendation was also approved, and the advertisements issued, the committee reporting that "we" have "drawn up the necessary particulars." The specification was, as a matter of fact, unsigned, and the name of the engineer responsible for it is unknown. Tenders came in on October 4 from all the noted firms. These were opened and referred to a sub-committee for report. This sub-committee consisted of four members and the surveyor, and they soon found the need of expert advice. In spite of the unsettled state of the scheme, tenders were then obtained for preparing the site for the buildings and for doing the excavation work. Then Mr. A. H. Preece was, in March of this year, appointed consulting engineer. He advised that of the tenders received those of Messrs. Ferranti and Co. and Messrs. Siemens Bros. were most favourable. To decide between these he advised that new specifications should be issued to these firms to include rectifiers, and finally the tender of Messrs. Ferranti and Co. was accepted. We trust that the work will now progress favourably, but think it would have been more fair to the contractors and more advantageous to the Vestry to have retained the expert to draw up the first specification. We concluded that every tender sent in had to be detailed by the contractor, and hence that no less than 11 firms had to do practically the work of a consulting engineer. We do not wonder in such a case that expert advice was needed to select the most favourable offer.

Glasgow.—A meeting of the Tramway Committee has been held to consider the remit from the Town Council asking that the committee should reconsider that portion of the minutes which had reference to the proposal to try by way of experiment the overhead electric system of traction on the detached route between Springburn and Mitchell-street. Councillor Colquhoun proposed that the matter be remitted to the sub-committee to obtain all necessary information and report. This was met by a direct negative by Councillor Oatts. After a stormy discussion, a division was taken, when seven voted for the motion and seven for the amendment. The chairman declined to give a casting vote. The result of this will be that the question of the electric motors will come up again before the Corporation. The Corporation Committee on Gas Supply and Electric Lighting have issued their annual report. The report, dealing with the fourth year of the electric lighting department, stated that the gross revenue for the past year amounted to £25,862 8s. 6d. and the gross expenditure to £11,589. 19s., and that, after accounting for depreciation, interest on loans, and additions to the sinking fund, their remained a surplus on the year's operations of £2,380. 19s. In view of that favourable balance the committee recommended a reduction in the price of current on a scale which necessitated that a new method of charging should take effect as from and after June 1 last. That new method, it was anticipated, would increase the popularity and use of the electric light. Indicators would be placed in customers' premises to ascertain the greatest quantity of electricity taken at any one time during the year, which quantity would be called the "maximum demand." To customers who used in the year the maximum demand for 365 hours only, being an average of one hour per day, or any lesser quantity, the price charged would be at the present rate 6d. per Board of Trade unit, but for all electric energy used over that quantity the charge would be at the rate of 4d. per Board of Trade unit. The committee also recommended the discontinuance of the charge for meter hire, and that the price charged for each lamp should be reduced from £26 to £20 per annum. The number of consumers at May 31 last was 855, being an increase of 269 over the number at the same date in the previous year. The quantity of electricity sold during the past year to private consumers, irrespective of public lighting was 866,606 Board of Trade units, being an increase of 24·11 per cent. The twenty-seventh report of the gas department showed a gross revenue of £605,794. 1s. 10d., with a surplus on the year's operations of £502. 12s. 9d. The committee recommended that the price of gas be reduced from 2s. 4d. to 2s. 2d. per 1,000 cubic feet. The quantity of gas sold or accounted for during the past year was 4,259,169,000 cubic feet, being an increase as compared with the previous year of 5·71 per cent.

Ipswich.—We briefly noted last week that the Town Council had postponed the consideration of the electric lighting scheme until October. The report of the Electric Lighting Committee was that, in accordance with the directions given by the Council, they took steps to oppose the grant to the County of London and Brush Provincial Electric Lighting Company, Limited, of a provisional order empowering them to supply electricity within the borough of Ipswich, and the result was that on March 16 last the Board of Trade wrote stating that they did not propose to proceed with the application. No expenses were incurred by the committee in the opposition, the matter being carried through by the town clerk. As the time had gone by for any outsider to give notice for the next session of Parliament, no provisional order could now be obtained by any private individual or company before July, 1898. The Council further empowered the committee "to consult Prof. Kennedy upon the question of electric lighting at a cost not exceeding £50." Having ascertained that his fee would be within the limit fixed by the Council, the committee requested Prof. Kennedy to give them details of the smaller scheme which he had previously mentioned, and in reply he forwarded a report. Having regard to the views already expressed by the Council on more than one occasion as to the necessity for including in the area for immediate supply streets which were not embraced in this report, it was considered desirable to obtain Prof. Kennedy's estimate of the cost of providing means for supplying electricity in four different areas (exclusive of public street lighting). Lists of the streets in these areas are given, but they would not be intelligible without a map of the town. The areas proposed vary from practically the two main streets to nearly all the important streets on the town side of the river and the lighting of the docks. Prof. Kennedy was also asked to ascertain what would be the total additional capital outlay required to provide for lighting the public streets in each of these areas by electricity. The committee substantially recommended a medium area, with the addition of the docks and quays. The estimate for this is: capital outlay required to provide means for supplying electricity, £25,000; for public street-lighting, extra, £2,500; professional fees and commission, say, £1,500; cost of provisional order, etc., say, £350; sundries, £350; total, £30,200. For the largest area the total is £41,900, while Prof. Kennedy's report as to the smallest scheme stated that the scheme was one which he mentioned in an answer to a question as to what amount of electric lighting could be carried out in Ipswich for about £18,000. The site for the station ought to be that called Canham's Marsh, at the back of the cattle lairs. About 32 arc lamps would be required to light the central part of the town and Princes-street as far as the railway station, and they were included. As to dust destructor, Canham's Marsh would suit admirably, and he had no doubt that, at any rate, the waste heat from the destructor could generate enough steam to keep the station going at times of light load, and consequently save a considerable amount of fuel. If a destructor were to be put down it would be as well that the matter should be decided at the same time as electric lighting. As to arc lighting for streets, Prof Kennedy's memorandum of June 1 stated that it would not be necessary to provide any special plant in the station. The additional cost of the arc lamps, therefore, was limited to that of the lamps and posts, with switches etc., amounting to about £32 per lamp. For the streets mentioned in the smallest (£18,000) scheme, 28 lamps would be required, costing £900; for the recommended scheme, 80 lamps, cost £2,500; for the largest scheme, 180 lamps, cost £5,700. In the smallest area there are a number of establishments already wired and fitted. These are at present either without current or supply themselves with gas-engines.

Ashton-under-Lyne.—Mr. S. V. Clirehugh, electrical engineer, in his first report to the Works Sub-committee of the Town Council, recommended a low-tension continuous current system, having regard to the fact that the area to be supplied is compact and thickly populated. The site of the generating station depended on the question as to whether refuse destructors are to be included in the scheme—*i.e.*, if destructors are used it is essential that the site at the town's yard be utilised. If, on the other hand, they are not, then the site by the Technical School might be used if there were very strong local reasons in its favour; but Mr. Clirehugh recommends the site at the town's yard for the following reasons: There is more land belonging to the Corporation than is ever likely to be required for the town's yard; there is a railway siding on the ground; there is a probability of sinking a well which would yield sufficient water for condensing purposes, or, if this is not possible on investigation, there is sufficient land to erect an evaporative condenser; and although not so central as the Technical School, the site may be considered sufficiently central for the purpose. Great controversy had arisen over the use of refuse destructors in connection with steam raising, certain experts maintaining that the conditions for a perfect destructor are directly opposed to the conditions required for obtaining the maximum calorific value of the burning refuse. More recent experiments had, however, shown that such was not the case, and the general consensus of opinion is that in the North of England 1lb. of refuse had a calorific value of about one-fourth to one-fifth of that of good coal. These figures are confirmed by the fact that many of the leading firms were willing to erect destructors under the most stringent guarantees as to their efficiency. From information supplied by the borough surveyor there was about 14,000 tons of refuse to dispose of annually, which was capable of maintaining 280 h p. continuously. The difficulty of utilising refuse to generate steam for electric lighting purposes only was due to the fact that electric lighting stations had a very bad load factor—that is to say, the works are only fully occupied for about two hours out of the 24, while refuse is continually coming in, and cannot conveniently be stored, or, if it could, provision could not be economically made for burning so large a quantity in so short a time. This brought forward the question of the advisibility of the Corporation supplying the tramway company with power. Mr. Clirehugh continued: "I have seen Mr. Sellon, the engineer to the company, on this subject, and he expresses willingness to enter into negotiations with the Corporation. In my opinion, provided the tramway company were willing to pay a reasonable sum per unit of power, it would be an excellent customer for the Corporation. They would probably require about 150 h.p. continuously, which would enable the refuse to be consumed as fast as it was brought in. The system is one of great advantage, as it enables the machinery to work fully loaded for a greater portion of 24 hours. Two well-known instances where the lighting authorities supply the traction company with power are at Hamburg and at Havre, and the Corporation of Swansea are also carrying out a similar scheme. When the points which I have raised in this report are settled, I shall be in a position to prepare

Digitized by Google

a scheme for the town and submit to you details of capital outlay, etc., required." After consideration of the report, the committee resolved that a continuous-current system should be adopted; that the town's yard site be adopted for the works; and that refuse destructors be employed in connection with the scheme; but that further consideration of the matter be deferred until the issue of the surveyor's report on destructors and the sub-committee's visits to inspect them. It was also resolved that the Corporation should supply the tramway company with power, and that the town clerk should write to the company informing them that the committee approved of their suggestion, and requesting them to consult with Mr. Clirehugh on matters connected therewith. The Market and Lighting Committee were requested to consider and decide as to which streets it is desirable to lay electric light mains in for street-lighting purposes. On all this coming up in the Town Council the minutes were confirmed. The Market and Lighting Committee had resolved that the Electric Lighting Committee be requested to lay mains for street-lighting purposes in a long list of streets, and this recommendation was passed on the motion of the Mayor, seconded by Councillor Chadwick.

PROVISIONAL PATENTS, 1896.

AUGUST 10.

17643. **A pocket electric lamp for use by surgeons and the like.** Robert Anderson Smith and Frederick George Bowley Green, 154, St. Vincent-street, Glasgow. (Complete specification.)

17657. **Improvements in electrical indicators.** Hugo Korten, 1, Park-terrace, Archway-road, Highgate London.

17659. **Receptacle for electric and other wires.** Edward Fenn Jones, 13 Eastcheap, London.

17661. **Improvements in electric pendulum indicators.** Frederick Jones, 7, Berber-road, Wakehurst-road, Wandsworth Common, London.

17666. **Improvements in automatic maximum speed governors for electrically propelled vehicles.** Horace Field Parshall, 70, Chancery-lane, London.

17671. **An improved method for obtaining porous metals by electrolysis.** Ludwig Hoepfner, 45, Southampton-buildings, Chancery-lane, London.

17701. **Improvements in electrical switching apparatus.** Henry Edmunds, 47, Lincoln's-inn fields, London.

AUGUST 11.

17818. **Improvements in dynamo-electric machines.** The British Thomson-Houston Company, Limited, 70, Chancery-lane, London. (David P. Thomson and Albert H. Armstrong, United States.) (Complete specification.)

AUGUST 12

17832. **Improved arrangement for lowering the globes of arc and other lamps.** Haldane Gwilt Cotsworth, 125 Merton-road, South Wimbledon, Surrey.

17846. **Improvements in telephone switchboard plugs.** The Telegraph Manufacturing Company, Limited, and James Taylor, Helsby, near Warrington.

17879. **Improvements relating to electric batteries.** Vincent Marie Cornely and Louis Charles Henry Dautel, 6, Breams-buildings, Chancery-lane, London.

17890. **Improvements in batteries for the electric lamps of cycles.** Ernest Tilmann and Charles King Lexon, 22, Southampton buildings, Chancery-lane, London.

17906. **Improvements in crossings of electric conductors for electric railways and tramways.** Albion Thomas Snell, Charles Edward Grove, and Arnold Frank Hills, 47, Lincoln's-inn-fields, London.

AUGUST 13

17915. **Improvements in means for the manipulation of electric lamps.** Arthur James Ireland and Charles William Godson Little, 20, Lawn-crescent Kew Gardens, London.

17951. **Improvements in continuous-current generator dynamos or motor dynamos.** Albert de Puydt and Maximilien Poncin, 60, Queen Victoria-street, London.

AUGUST 14.

18005. **Improvements in electromagnetic gearing.** David Cook, 30, Lancaster-park, Richmond, Surrey.

18046. **Improvements in electric accumulators or secondary batteries.** Mich'l M Brophy and Joseph Devonport Finney Andrews, 45, Fulham Park-gardens, London.

18053. **Improved means or appliances for supporting revolving shafts, and the arrangement of rotary motors and dynamos in connection therewith.** Reginald Wood, 28, Southampton-buildings, Chancery-lane, London.

18076. **Improvements in or relating to direct-current dynamos and electromotors.** Francis Henry Davies and Charles Orme Bastian, 31, Southampton-buildings, Chancery-lane, London.

18080. **Improvements relating to telegraphs.** Albert Edward Collyer, 55, Chancery-lane, London.

AUGUST 15.

18103. **Improvements in electricity and other supply meters.** Matthew McAuley Gillespie and William Richard Wynne, 20, Craven-road, Harlesden, London.

18107. **Improvements in and relating to electric lights and installations.** Jabez Jackson, Linton House, Starley-road, Coventry.

18118. **Improvements in electric lamps for velocipedes and vehicles and in the method of generating and storing electrical energy therefor.** Albert Montague Armstrong, 59, Derby-road, Croydon.

18134. **Improvements in and connected with electric conductors and in means for making connections therewith, the invention being particularly applicable for theatres and the like.** George Heys Jones, 55, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1895.

13702. **Apparatus for regulating or measuring electric currents.** Pieper.

14134. **Rapid telegraphic transmission on cable lines.** Langdon-Davies.

16042. **Compound electrical testing switch.** Norman.

16494. **Supports for overhead electric conductors.** Lake (Goodwin).

17526. **Electrical transformers.** Berry.

17655. **Secondary batteries.** Drake and Gorham.

17656. **Spring contact switches.** Drake and Gorham.

22505. **Active material for electric accumulators.** Dannert, Windolff, and Zacharias.

1896.

3690. **Electromagnetic induction system of supplying power to electrically propelled vehicles** Shuttleworth.

12345. **Automatic apparatus for the working of telephone stations.** Naglo.

13263. **Friction grip for sliding rods applicable to holders of electric lamps, carbons, and the like.** Preece.

NOTES.

Motorcars in Paris.—By a decision of the Prefect of the Seine, horseless carriages have just been admitted to all the rights and privileges for public service of the ordinary *fiacre*. The step is a wise one, and it will be interesting to watch the progress of the competition. If some such by-law were made in a few large towns in England the industry might soon become a great one, but all the while it is confined to Crystal Palace exhibitions it is not calculated to make the fortunes of many people.

Motorcar.—The *Morning* has an interesting note to the effect that in St. Margaret's Church, Westminster, there is a memorial window to Sir Goldsworthy Gurney, the inventor of the limelight, and also the inventor and conductor of the first locomotive carriage along ordinary roads. Sir Goldsworthy took a steam locomotive carriage from London to Bath, having for passengers the first Duke of Wellington and Sir Francis Burdett. In the vestry of St. Margaret's there is an extremely rare and interesting engraving of this first road locomotive.

Argon in Combination.—The Paris correspondent of one of the daily papers has just heard of an interesting discovery made by Prof. Villard. Ever since the discovery of argon, chemists have tried with indifferent success to make combinations between this gas and its sister elements. Prof. Villard, of the Ecole Normale, has at length prevailed upon this element to combine with water. He found that no pressure short of 200 atmospheres would coerce argon into combination with water. The compound is colourless, and crystallises very prettily when kept cool.

A Russian Invasion.—Journalists in St. Petersburg have been busy chronicling what they describe as a series of remarkable telephonic experiments which have recently been made in Moscow, in the course of which messages, airs, and songs were conveyed by means of M. Keldushoffsky's new telephone between Moscow and Rostoff on the Don. The distance between these two towns is 1,340 versts, or 900 English miles, whilst the wire used on this occasion was over 1,800 miles long. It is stated by the representative of the Moscow *Gazette* who witnessed the experiments, that the inventor of this new telephone soon intends visiting England in order to see whether telephonic messages cannot be conveyed from England to America by means of the Transatlantic cable.

The Eclipse of the Sun.—The Russian Astronomical Expedition which was sent to the North of Finland to observe the solar eclipse, telegraphs from Tornea that owing to the magnificent weather which prevailed at the time, 10 good photographs of the corona were obtained by means of three different apparatus. The Hydrographical Department has received a telegram from General Baron Maidelicheff, of the Saghalien astronomical expedition. The message, which was despatched from Cape Notoro, the south-western extremity of Saghalien, states that the observation of the eclipse was fairly successful and that, although the sky was cloudy, two photographs of the corona were obtained. Some magnetic variations were noticed during the eclipse. It would be interesting to know whether the observers attributed the magnetic variations to thermo-electric effects.

A Curious Lamp Deformation.—A curious deformation of a lamp occurred some time ago in a German theatre. The lamp in question was a 20-c.p. 110-volt incandescent, and was fixed in a horizontal position to a wall in the flies. A "super" was, however, instructed to cut out this lamp, and having not knowledge of the technicalities of electric lighting failed at first to do so. He finally dimmed the offending lamp by wrapping round it a towel, on which the remains of "make up" and make-up grease were well in evidence. The result was that the heat of the lamp so softened the glass of the bulb that from a horizontal it fell into a semi-vertical position, and the glass coming in contact with the filament broke the latter. The cloth was badly scorched, but did not ignite. The lamp did not break. The illustration accompanying this information in our New York contemporary shows the effect of the vacuum on the softened glass.

Stirring up an Electric Battery.—An amusing case over the damage done to an electric battery was tried recently at Sunderland, and shows the hardship automatic penny collectors have to put up with. Evidence showed that the "electric battery" was in good order when supplied to the defendant, an innkeeper; in fact, several tried it and all were shocked. The machine afterwards was supposed to have acquired the dishonest practice of absorbing pennies without shocking the givers. The landlord then told his customers to hit it with something hard. A soda-water bottle seems to have given satisfactory results for a time, but one night the machine was assaulted with a poker to the extent of £5. 8s. 6d. This, and the language used, was too much for the works, and the owner of the unlucky machine finally obtained judgment accordingly. We suppose that the theory of hitting it with something hard originated from a knowledge of the ways of the wet gas-meter.

The Falls of Foyers.—The proverb, "Where the carcase is there will the eagles be gathered," can be renovated to read, "Where the power is cheap there will be found the manufacturers." At Niagara a number of new factories and a new town is springing up in consequence of the power available for harnessing in the large falls there. Again, at Foyers the power available caused the British Aluminium Company to establish works there to the great advantage of the inhabitants. We now hear that the Acetylene Illuminating Company have arranged to share the advantages of the site and of the water power rendered available by the enterprise of the British Aluminium Company. By the arrangements entered into between the two companies, works will be erected which will require several thousand horse-power for the manufacture of calcium carbide. Until these works are complete power will be taken from the dynamos of the British Aluminium Company, as described in our issue of May 8. A carbide plant is now being erected, and it is expected it will be in full swing during October. We are glad to chronicle the fact that this valuable product is to be made in Great Britain.

Locomotives on Highways.—We regret to note that the impetuosity of an electrical engineer at Westminster to distinguish himself as the owner of self-propelled vehicle has led the gentleman in question into trouble. The police station charge stated that the motorcar was driven twice round Parliament-square at a pace of four miles an hour. Defendant, when spoken to, said he had the permission of Sir E. Bradford to try the car on the public road. It seems that this was not the first offence, but after the passing of the new Act the defendant could not refrain from furious driving. In the interest of the public such high speeds are thought to be dangerous. The gravity of the case was evidently derived from the fact that the same thing had occurred before, and that although the Commissioner of Police had given permission for the cars to proceed along the roadway on specific occasions to various exhibitions, he would not countenance a general use of the car in the streets. The magistrate said that people must learn that they could not drive motorcars in the street

Digitized by Google

except under stringent regulation. We feel that the electrical engineer in question was rather premature in the use of his car, and trust that his experience will save others from falling into the same error before the Act comes into force.

The Chemists' Exhibition.—The second annual Chemists' Exhibition, held this week, has undoubtedly proved a success. The stallholders numbered 124, twice as many as last year, and it is even stated that many applications for stall room from members of the various trades interested had to be refused. The appearance of the show was that of practical utility rather than sensational display. Such things as mineral waters, and the appliances used in its manufacture, formed a striking contrast to an exhibition of the Röntgen rays, but it was a healthy sign to see that all branches of investigation covered by that useful section of civilisation, the chemists, could be brought together in one collection for scrutiny and comparison. All the well-known firms were represented at this exhibition in the National Skating Rink, Argyle-street, W. Among the other attractions was the Hungarian Ladies' Orchestra, of which Mdlle. Kati Erl is the conductress, whose finished performances added much to the enjoyment of the visitors.

Is Aluminium Poisonous ? — A correspondent describes the following experiments in the columns of the *Morning Post*: Recently two healthy and robust physicians, aged 26 and 35 years, were selected by the Imperial German Health Bureau to undergo an interesting experiment. These two gentlemen, in order to test the non-poisonous properties of aluminium, volunteered every morning for one month to swallow 15 grains of aluminium tartrate with their lunch. At the end of the trial neither of them had lost flesh nor appetite, or experienced the slightest discomfort during the entire period of their metallic lunch. It is found that the metal is not adapted to contain for a lengthened period brandy, whisky, or wine. After a time these turn turbid, and, although perfectly harmless, are not inviting even to the thirsty traveller, who, however, need not fear filling his flask for a two or three days' journey. The correspondent has used cast-aluminium cooking utensils for over 12 months, and they have given both the cook and the consumer every satisfaction, without any fear of poisoning as when using copper utensils. Dental plates are now made in aluminium, which, besides being only a fraction of the weight of gold plates, possess the additional advantage of producing no disagreeable taste in the mouth.

The Institution of Junior Engineers.—The summer meeting of this institution has just been held in Scotland. The members have visited several of the large towns, and have met with a very hospitable and cordial reception. Among the towns visited was the royal burgh of Dumbarton, where they were officially received by the provost, magistrates, and Town Council, and visited some of the public works in the town. The company, which numbered about 50, travelled to the town by a train arriving shortly after 10 o'clock, and were there received by Mr. Archibald Denny, president of the institution, and a partner in the firms of Messrs. Denny and Bros., shipbuilders, and Messrs. Denny and Co., engineers. From the station they proceeded to the Lesser Burgh Hall, where they were met by Provost Garvie, Bailies Barlas, Henderson, and Young, the other members of the Town Council, and a number of other gentlemen. Leaving the hall the party, accommodated in wagonettes, drove round the town by way of Levengrove Park and the Castle, returning to the Leven Shipyard, where, on the invitation of Messrs. Denny and Bros., luncheon was served in the model hall. Votes of thanks to the Town Council and the firm of Messrs. Denny and Bros. were then awarded. The party were then shown through the Leven Shipyard, and subsequently the forge and the engine works were visited.

Electrocution.—The following editorial from the *Electrical World* of New York is worthy of full notice, as it is not often that sentiment is allowed to obstruct business in America. The editor says: "It will be remembered that the last Ohio Legislature passed a measure which went into effect on July 1 legalising electrical executions in that State. The making of a law is one thing and fulfilling its requirements are quite another, as the Ohio penitentiary officials are discovering to their dismay. They are experiencing unforeseen difficulties in securing an alternator to carry out their deadly work. That the various manufacturers of the necessary electrical machinery have no desire to sell their apparatus for such purposes is evidenced by the fact that no response was received to the invitation for bids for the death-dealing outfit. When electrocutions became lawful in New York State the penal authorities encountered the same difficulties, so that it was only by resorting to considerable strategy that an alternator was secured. It is not unlikely that the Ohio officials will be compelled to seek the same means to attain their end. The objection of manufacturers to selling electrical machinery for the purpose of killing human beings is not one of sentiment alone. It is no recommendation to apparatus of any kind to have it used, even by the constituted authorities, for the purpose of taking human life."

Assistance to British Trade Abroad.—Since the present Government came into power they have given very attentive consideration to the question of British commercial interests abroad. In the Consular and Commercial Departments of the Foreign Office the following suggestions have the approval of the Secretary of State. Two new commercial attachés will be appointed, one to Germany, the Netherlands, and Scandinavia, to reside at Berlin, the other for Spain and Portugal, to reside at Madrid. The commercial attachéship at Paris has been reorganised, and its district will in future cover France, Belgium, and Switzerland. The commercial attachéship in Russia and Western Asia has also been reconstituted, and the south-eastern parts of Europe have been included, while Asia has been excluded from its sphere. A consul for Lombardy has been appointed to reside at Milan with a special view to the collection of commercial information. The consular staff in Siam will be increased by two new appointments, but the exact areas of the new consuls' jurisdictions are not yet fixed. Other important appointments are under consideration also. As a result of communications which have passed between the Foreign Office and the Association of Chambers of Commerce, supplementary instructions are in course of being issued to her Majesty's consuls regarding assistance to trade, the collection of samples, and information of a commercial nature. More complete arrangements have recently been made for the immediate publication in the Press of invitations for tenders for work abroad. We trust that the effect of these steps will be to increase our exports of electrical goods.

The Everlasting Rontgen Ray.—The correspondent of the *Standard* sends the following information from Toulon, culled from the columns of the *Petit Parisien*, to the effect "that the Active Squadron of the Mediterranean has just effected experiments with a new method of signalling. The squadron left Marseilles on 20th inst., at five o'clock in the evening, leaving behind it the torpedo-catcher 'Faucon,' which weighed anchor the same evening at eight o'clock. The 'Faucon' was to find the squadron during the night, though all the vessels were sailing with-

Digitized by Google

out lights. The 'Faucon,' by the aid of what has been named by the common sailors the *feu de ratière*, succeeded in discovering the squadron by one o'clock in the morning. This *feu de ratière* is a very small apparatus, which, it is said, throws electric rays which cannot be perceived either on the right or the left, but simply in front of the apparatus. It produces no reflection, and the light can, it is affirmed, only be seen under special conditions known to none but those working it. This light will, it is said, also serve for signalling at night when it may be desirable to avoid an enemy understanding signals made by rockets. It is claimed for it also that it will serve to guard a squadron steaming in file with extinguished lights." We are informed "that no foreign navy possesses this apparatus invented by a French naval officer, and it can be easily understood that our squadrons should guard the secret jealously. Only the commander of the ship and a non-commissioned officer working it, who have taken an oath not to divulge the secret, are at the present moment acquainted with it. The apparatus is carefully kept in a cabin, of which the commander of the 'Faucon' alone has the key." How a non-reflecting light can assist the search party we fail to see.

Paris and Glasgow.—*Cosmos*, which rejoices in a headpiece truly astounding in its *naïveté*, is one of our contemporaries whose function is the dissemination among the inhabitants of France of popular science—always subject to the strict limitations of what is considered good for them. Apparently the molecular theory on which is the basis of modern chemistry, is one of the things which is not good for them. It is thought to lead to "anarchism" and views on other subjects which we do not treat of in these columns. Consequently, when Mr. de Fonvielle, of *Cosmos*, made the discovery that Lord Kelvin had declared that theory was a feeble one, he was much pleased, and wrote to congratulate "Sa Seigneurie." Apparently he would not presume to speak of a man who had made such a discovery merely as Monsieur le Baron. The letter, which is published in full in *Cosmos*, is a very curious one. Nothing, it seems, that Lord Kelvin has ever done can exceed in importance his pronouncement on the subject. Lord Kelvin replied in a dignified letter, which, when translated, makes exceedingly good French. He had been slightly misunderstood—that is all—and was alluding only to the weakness of his efforts in the work of explaining the cause of things; in fact, he had never been more certain of the absolute truth of the kinetic theory of gas than he was at that moment. There are those, we know, who do good by stealth and blush to find it fame, but Lord Kelvin must have been slightly astonished when he discovered this particular contribution of his own to the progress of science, and the more so, as Mr. de Fonvielle is apparently by no means still convinced that "Sa Seigneurie" of Kelvin does not really think as he was at first believed by our contemporary to do on the subject.

An Automatic Electric Lift.—A communication to the *Electrical World* by Mr. Theodore Water, on electricity in private houses, contains a description of an electric lift which is automatic. The pressure of a single push button on each landing is all that is necessary to bring the car to that particular landing. The car having arrived at that landing stops automatically. The door of the shaft is then unlocked, and may then be opened and the car entered. When the door is open the whole system is electrically beyond control, and no part of the machinery can possibly move until the door has been closed. For instance, if someone after using the elevator should carelessly leave the door partly open after him, it would be impossible to call the car to any other floor, it first being necessary to shut that door. This precludes the possibility of an accident happening through a simultaneous attempt of two persons to operate the elevator from different floors. There is but a single push button on each floor which performs the function of calling the car in either direction. Within the car three buttons are used. These are labelled "up," "down," and "stop." A simple electromagnetic gear in the cellar regulates the automatic movement of the car. The whole system is good for country houses provided the gear is reliable. The author proceeds afterwards to describe the electric indicating gear fixed to each bedroom of this model house. A long plumb-bob shaped frame containing four pushes is hung at the head of each bed. The pushes are labelled "asleep," "awake," "closed," "locked," and work indicators outside the door. This is for the use of servants, we are informed. The mistress of the house can in this way let the servants know whether she is asleep and if the door is shut. Provided the accuracy of the first signal can be depended on, the apparatus should command a large sale. We are told that the last two pushes automatically close and lock the door.

The British Association.—The arrangements for the sixty-sixth annual meeting of the British Association for the Advancement of Science, which opens at Liverpool on Wednesday, September 16, have now been almost completed by the local committee, of which the Lord Mayor (the Earl of Derby) is the chairman. Many foreign men of science have notified their intention to be present, and an invitation has been sent to Dr. Nansen, who it is expected will be able to attend and give an interesting account of his recent exploits in search of the North Pole. On the evening of the opening day Sir Joseph Lister, Bart., will deliver his presidential address in the Philharmonic Hall. The sectional meetings will commence on the following day, and these will be continued until Wednesday, September 23, when the concluding general meeting will be held in St. George's Hall. The list of sectional presidents includes the names of Prof. J. J. Thomson, Dr. Ludwig Mond, Mr. J. E. Marr, Prof. E. B. Poulton, Major L. Darwin, the Right Hon. Leonard Courtney, M.P., Sir Douglas Fox, Mr. Arthur J. Evans, Dr. W. H. Gaskell, and Dr. D. H. Scott. The public lecturers of the week are to be Dr. Francis Elgar on "Safety on Ships," Prof. Flinders Petrie on "Man before Writing," and Prof. J. A. Fleming on "The Earth a Great Magnet." Excursions are to be made to Chester, the Manchester Ship Canal, the saltworks at Northwich, the Rivington and Vyrnwy Waterworks, and the London and North-Western Railway Company's works at Crewe. In addition to the invitation of the Earl of Derby to visit Knowsley, invitations have been extended to the association by the Duke of Westminster and Mr. Gladstone to visit Eaton Hall and Hawarden. One or more marine dredging expeditions will be organised. The larger excursions will run to the Lake District and the Isle of Man, the latter to last over five days; and Liverpool itself, of course, has much that is of interest to show, and which will be new to the association, for 26 years have elapsed since its last visit to this populous seaport.

The Insurance of Electrical Plants.—Mr. R. H. Pierce read a paper on this subject before the North-Western Association in America, and he is to be congratulated on the grip he has taken of the subject. We in England have complained of the high rates, but are not so ready as Mr. Pierce to acknowledge the reasons for these rates. The author justly puts the loss of public confidence due to interruptions at a higher value than the actual loss of machinery in case of fire. He adds that, "As a good share of the existing stations need to be rebuilt in order to

Digitized by Google

have a decent earning capacity, the loss of plant may in many cases be considered less of a hardship than the losses through interruptions of the service." The author considers that the question of insurance can be met in three ways : (1) By insuring in responsible and reliable insurance companies. (2) By the formation of a mutual company by central-station owners. (3) By securing the maximum safety through the use of proper construction, care, and fire protection, and taking the chances of a fire loss. As a general proposition, the only reasonable course is the first one indicated—*i.e.*, the insuring in responsible and reliable companies. The plan of forming a central-station owner's mutual has been "weighed in the balance and found wanting." Theoretically, it may be possible to form such a mutual company, but it would be an additional burden to the central-station business, which, I take it, has trouble and problems enough to face already. If fire insurance is a legitimate business—and it appears to be as legitimate a business as electric lighting—then we may as well assume that the insurance people know their business, and that the competition between insurance companies will produce as low a rate as could, with equal protection, be given by a mutual company. The third method mentioned, of securing maximum safety and then taking the chances, may be the best in some, but only in very special cases. If the central-station plant is so designed, installed, and operated as to reduce the fire hazard to a minimum, insurance companies will ask a minimum rate of insurance, which in most cases will be so small as to be no burden to the owners. Discarding, then, the two plans just mentioned, we are brought to the first plan of insurance in reliable companies. Accepting this as our line of action, the problem now is to so instal and operate our plants that the hazard is reduced to a minimum, or at least to a point where further improvements would increase the cost out of proportion to the additional safety secured. Mr. Pierce proceeds to detail the present regulations of the National Board of Fire Underwriters, and to support the policy of increasing the premiums where their requirements are not fulfilled.

Rectified Current for Motors.—Mr. J. B. Hall communicates to the *Canadian Engineer* some particulars of an installation at Wentworth, Ohio, erected some three years ago. The village was lighted by alternating current, and a direct-current motor was installed in a newspaper office. The method of driving this motor from the alternating-current mains was as follows : The primary alternating current leads at 2,000 volts and 133 cycles were connected to the primaries of two transformers in parallel. The secondaries of the transformers were connected in series giving 200 volts. A synchronous motor was, however, connected to the common terminal of the two secondaries so as to get 100 volts at its terminals. The transformers were each 75 lights capacity of a standard make. The synchronous motor was of the earliest Tesla type, and had been used before to drive a small fan; this was removed, and in its place was put a commutator, which consisted of eight segments, fastened to a fibre back with air insulation between; the brushes were of carbon, and the combination was very effective in minimising the evil from the small spark that necessarily occurred. With mica between the segments, both the brushes and the commutator were burned, but without mica the brushes alone were disintegrated. The connections past the rectifying commutator were the same as is used in direct-current installation for a shunt motor. The method of working was to start the synchronous motor, and when it got up to speed to close main switch. This excited the field coils, and the circuit of armature was then made through a rheostat. The motor was a five-kilowatt undertype, with a tested commercial efficiency of 83 per cent. To find the efficiency of the combination, a five-kilowatt dynamo of 83 per cent. efficiency was directly coupled to the motor, and the current generated from it was passed into a water resistance. Measurements of that circuit were made by a Weston portable volt and ammeter and Edison chemical meter. The alternating circuit was measured by a Thomson wattmeter, and by a Westinghouse (Shallenberger) alternating-current meter. The test was of four hours' duration, and the following results were noted: The synchronous motor required about 150 watts. The Thomson wattmeter registered 30,964 watt-hours; the Westinghouse meter, 31,236 watt-hours; making an average of 31,100 watt-hours. The ammeter recorded 26·8, the voltmeter 190, each the average of quarter-hour readings; the weight of the plates in the chemical meter indicated 20,980 watt-hours. Taking the measurements as being correct, the efficiency of the combination would be about 66 per cent., or of the motor and rectifier 81 per cent. The fields of motor became a little warmer with a rectified alternating current than with a continuous current, but no loss in efficiency seemed, in the author's opinion, to be traceable to the eddy currents and hysteresis resulting therefrom.

A Reassuring Notice.—The Wire Department of Boston has issued the statement below in hopes of preventing panics in street cars: "In view of the large number of accidents that have occurred in this and other cities and towns throughout the country, due to the use of electricity as a motive power on street railways, and the panics which ensue among passengers when certain things take place that are inevitable and others that are not, the Wire Department deem it advisable to issue the following statement for the benefit of the great number of people who ride on the street cars : There are four things that are sure to occur to the electrical equipment of a street railway with a certain degree of regularity : the melting of fuse metals, burning out of motors, burning of the insulation of wires under the floors or on the roofs of cars, or breaking and melting of trolley wires. All these when they have occurred in the past have often caused a needless panic, resulting in serious injury to some of the passengers. The fuse metal would not perform its proper function if it did not melt at the proper time, and thus prevent a burning out of the motor. They often melt without any noticeable effect, but there are times when they vaporise with a vivid flash and loud report that is somewhat startling; but no injury can occur to the passengers on the car from the 'blowing' of a fuse if they will remain quietly in their places. As yet there is no means of effectually preventing the burning out of electric motors, which will occur at times on the best regulated street railroads. When this happens it will not cause the slightest injury to passengers who still remain quietly on the car until it stops. The effect produced may be somewhat startling at times to the great majority of people who ride on the cars and prompt them to seek safety in precipitate flight from seeming danger; this has often resulted in personal injury to those who do so without stopping to think of the consequences. All grades of insulated covering now used for electrical conductors are perishable, and its failure at times is to be expected. Nearly all the materials used for this purpose are inflammable. For various reasons not necessary to enumerate, the covering on the electric wires in street cars take fire and burn, but not rapidly, and, as a rule, the other portions of the car are seldom damaged. Here, again, there is no danger to the people on the car if they wait until it stops, when they will have ample time to leave it quietly. The trolley wires will and do break at

Digitized by Google

times, but in doing so they will not injure those persons who remain in their seats. If it is necessary to leave the car, do it leisurely and quietly and avoid the broken ends of the trolley wire; it will not injure anyone who does not touch it. While it may give marked evidence of the energy it transmits when in contact with the wet ground or some other good conductor, it will not harm the passer-by who avoids it. Let all remember that this (to them) mysterious power is controllable, even though it does kick over the traces at time."

The Postmaster-General's Report.—The fifty-second annual report of the Postmaster General for the 12 months ended March 31, 1896, shows that during the year 78,839,610 telegrams of all descriptions were forwarded, showing an increase over the previous year of 7,250,546, or 10·12 per cent.; 64,563,587 of these were ordinary inland telegrams—*i.e.*, excluding foreign, Press, and free telegrams—showing an increase of 5,656,179, or 9·6 per cent. The total revenue from inland telegrams was £2,046,456, as compared with £1,880,206 for the previous year, the average revenue 7·61d. per telegram, as compared with 7·66d. The number of foreign telegrams dealt with by the Department reached 6,701,838, showing an increase of 764,123, or 12·86 per cent., as compared with the year 1894-95. This total does not represent the whole of the foreign telegraphic business of the United Kingdom. It only shows the number of foreign telegrams transmitted by the Post Office, and does not include those dealt with by the various cable companies without recourse to the postal telegraphs. 5,915,646 telegrams were transmitted at the Press rates for newspapers, clubs, etc., being an increase as compared with the previous year of 513,863, or 9·5 per cent. The average weekly number of words contained in these telegrams was about 13,650,000. Telegrams sent on behalf of the various Government departments show an increase of 22,722, or 8·33 per cent., the total for the year being 295,371, as compared with 272,649 for the previous year. The number of telegrams sent free of charge on behalf of the railway companies amounted to 1,338,818. The large increase in the number of telegrams passing over the Government cables to the Continent, and in the number of conversations on the telephone circuits between London and Paris, has rendered it necessary to consider the advisability of improving the means of communication. Arrangements have now been made for the laying of three additional cables to the Continent—two to France and one to Germany. These cables, each of which will contain four conductors, will afford a much-needed relief to the traffic. The new agreement with the National Telephone Company, embodying the arrangement arrived at after prolonged and difficult negotiations extending over nearly four years, was executed on March 25 last. In accordance with the terms of the Treasury minute, on which the negotiations are based, the agreement restricts the operations of the company to local areas, and places the trunk wires connecting those areas in the hands of the Post Office. It has not yet been found practicable to transfer the working of the whole of the wires to the Post Office, as the special arrangements for leading in the wires and fitting the necessary switchboards, etc., must necessarily occupy some time. The only wires the working of which has at present been transferred are those in the South of England. It is anticipated that the working of the whole of the remaining wires will be in the hands of the Post Office by the end of the summer. The telephonic service on the main system of trunk lines erected by the Department itself between the principal business centres of the United Kingdom to supplement those which it has now acquired from the National Telephone Company was successfully inaugurated on June 12, 1895. On July 16, 1895, the system was thrown open to the public, and there has since been a steady development of the business. During the year additional telephone circuits between London and Bristol, London and Southampton, London, Lowestoft, and Yarmouth, and London and Guildford have been completed, while further circuits between London and Birmingham, Liverpool and Manchester, Manchester and Carlisle, and Newcastle and Carlisle are in course of construction.

The Telephone in Deafness.—It is well known that in most cases of deafness the actual hearing part of the apparatus, so to say, is capable of performing its function, but the mechanism for collecting the sound waves and transmitting them to the cochlea and its appendages is defective. It is not, however, so well known that this is also the case, at least to a considerable extent, in an appreciable proportion of cases of deaf-mutism. The reasons why this should be so are exceedingly interesting, but somewhat outside our range. It must therefore be taken as a matter of fact that that percentage exists. In cases of this character, and, indeed, in all really bad cases, with the ordinary speaking-tubes and trumpets, it is essential that the mouth of the speaker should be directed into, and closely applied to, the orifice of the instrument. By this means it is well known that the intensity of the voice of the speaker is increased to an almost painful degree, but the effort of keeping the mouth applied immediately to the mouth of the tube or trumpet prevents the hearer from witnessing the movements of the lips and general expression of the speaker—a most important consideration with deaf people. By using the telephone, however, it has been found that there could be produced an intensification of the voice at least equal to the most approved form of ear-trumpet at a distance varying from 6in. to 1ft. from the mouth of the transmitter. In an article on the subject in the *Lancet*, Dr. Bertram Thornton, medical officer to the Deaf and Dumb Asylum at Margate, describes some investigations he has made on the subject, and adds, "in the experiments I have made with patients suffering from lesser degrees of deafness than the deaf-mute children at the Margate Asylum, the utility of the telephone has been proportionately more apparent. I will mention two cases in illustration. The first was that of a young woman with nerve deafness so extreme that it was necessary to speak at the top of one's voice within two or three inches of her ear to enable her to hear, but with the telephone I was able to converse in a subdued voice with my mouth 26in. away from the transmitter; in this case she received some assistance from reading my lips, though she was only a beginner in this accomplishment. The second case, a man with a similar degree of deafness, was able to hear his wife and myself conversing with him in tones hardly raised above a whisper, we being inside a room and he being outside with the door shut. Whether future experience will bear out my preliminary investigations only time will show; the opportunities of a provincial surgeon for carrying out extensive scientific observations are naturally limited." In the article there is given a short reference to the form of portable telephone employed, and a suggestion is made that the apparatus should be called a lamprophone. As for this latter point, since the instrument consists only of a transmitter, receiver, and three dry cells in a box, there does not seem any reason why it should require to give up its old name and take a new one, any more than do the induction coils and magnetos that are already in surgical use.

RAILWAY BLOCK SIGNALLING.

BY J. PIGG.

(Continued from page 206.)

In a previous article reference was made to the liability to accident where the construction of the block instruments is such as to allow of the line being cleared before the train so signalled is out of the section. Such action, resulting from a lapse of memory on the part of the signalman at the receiving end of the section, was found to be cause of a very bad accident a few years ago. An experimental attempt to neutralise the effects likely to arise in this way for a three-wire single-needle circuit is shown by Figs. 48, 49, and 50.

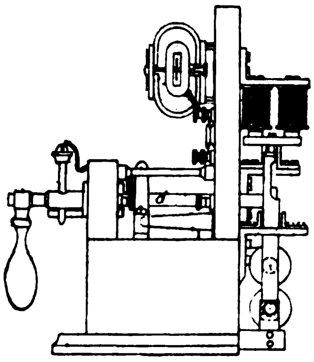

FIG. 48.—Case Removed, Instrument Locked (Right Elevation).

As will be seen from the figures, the apparatus provides for the locking of the instruments to "Train on line," after the usual distinguishing signals have passed, until the train, so signalled, has passed over a rail treadle, placed at a suitable point near the cabin at the receiving end of the section. The locking takes place at the receiving end of the section, and is due to concurrent action on the part of the signalmen at both ends.

The arrangement was not intended to relieve the signalman of the responsibility for seeing that the *whole* of a train previously signalled arrived and passed under the protection of his outdoor signals in accordance with the rules provided for working traffic, but was designed with a view to provide a check against any attempt he might inadvertently make to clear the line before the train reached a point which had previously been determined by the responsible officials to be outside the section referred to.

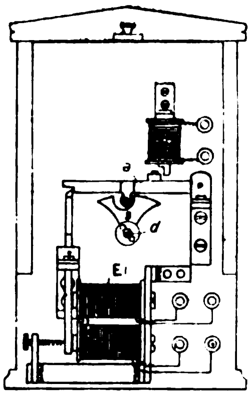

FIG. 49.—Back Elevation, Instrument Locked.

At the time the additional apparatus was designed, it was the rule for the signalman at the *sending* end to hold the instrument needles to "Train on line" until the signalman at the receiving end had inserted the peg as shown in Fig. 49. At the instant this was being done the batteries at both ends of the section were in use. Advantage was taken of this simultaneous use of both batteries to lock the handle of the receiving instrument in the "Train on line" position, so that if the peg was withdrawn before the proper time the instruments at both ends would still show "Train on line," and the signalman at the receiving end would be unable to move the handle to give "Line clear," or any other signal, until the instrument was unlocked by the direct action of the train signalled on its arrival at some point where at least a portion of the train had passed the signal cabin.

The additional apparatus consists of the differential electromagnet, E_1, which is connected as shown in Fig. 50, and the simple electromagnet, E, connected with the rail treadle. The commutator spindle, *d*, is prolonged through the back of the instrument, and carries the slotted sector, *s*. The rocking-bar, *a*, rides on the top of *s* when the handle of the instrument is vertical; and the armature of E_1 supports it, under the lower edge, during the time the instrument is being worked to send train-distinguishing signals, since E_1 is a differential electromagnet, and its armature is unaffected by currents originating at the receiving end.

During the time train-distinguishing signals are being received from the sending end of the section, the armature of E_1 is affected, but the handle of the receiving instrument being then vertical, *a* is upheld by *s*. If the handle of the instrument at the receiving end is held over so that the needles indicate "Train on line," the slot in *s* comes under the friction wheel of *a*, but the latter is still held up by the armature of E_1. If, now, the handle at the sending end is also held over, the previous balance of the currents in E_1 is upset, the armature is attracted and allows *a* to fall and lock the handle of the receiving instrument in the "Train on line" position. The only legitimate means of releasing the handle after the operations described is, as will be seen, by the current set up when the circuit of E is closed by the depression of the rail.

In Fig. 50 the handles of the instruments at both ends of the section are shown in the position to indicate "Train on line." It will, however, be clear from the description

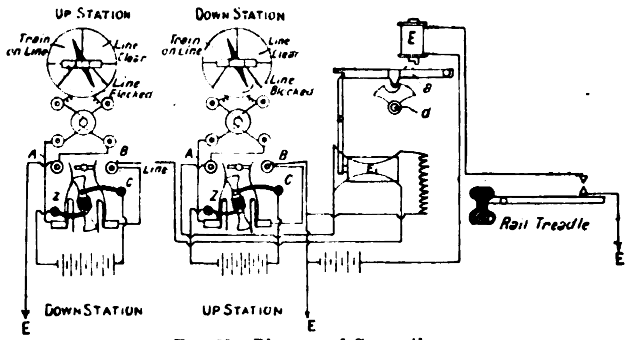

FIG. 50.—Diagram of Connections.

that the diagram represents the position of the handle at the sending station at the moment the instrument at the receiving station is being locked only. At other times the handle of the sending instrument stands vertical, as usual, and the "Train on line" indication is maintained by the position of the handle at the receiving end. As has already been said, this concurrent action of the two signalmen was the rule for working at the time the additional apparatus was designed. At present the method of working is different, but there is nothing in the requirements which is inimical to the working of the instruments as indicators.

The position of the releasing treadle requires judgment in its selection, and would probably, owing to local circumstances, be different at every place. Its position would also largely depend upon the rules in use by the particular company adopting any such method of automatic working. Some companies prohibit the acceptance of any train from the rear when the previous train is standing at the "advance" signal, although it is then protected by the "home" signal. Others prohibit the acceptance of passenger trains only under these circumstances, and allow goods or mineral trains to be brought to the "home" signal, when a similar train is standing at the "advance" signal, the "distant" being kept at danger during the approach of the second train.

Obviously, the point of release will be different in the two cases; for if the line may not be cleared until a train has passed the "advance" signal, the releasing point must be situated so that it cannot be actuated until the train has passed that signal, whilst, on the other hand, where the line is cleared when the train is within the "home" signal the releasing point must be selected at a point near that signal.

Digitized by Google

This difference in practice is worthy of more notice. In the case where the line is not cleared until the train is passing the "advance" signal, the section obviously extends between "advance" and "advance." Where the line is cleared when the train is within the protection of the "home" signal, the section extends between the "advance" at the sending end and the "home" at the receiving end, and the part of the line between the "home" and "advance" signals is practically unblocked and worked under the observation of the signalman only.

Winter's Block Instrument.

Fig. 51 shows diagrammatically the construction of and connections for Winter's block instrument as arranged for double-line working, with one line wire and using transient currents. All distinguishing signals are given by a bell code, and the indicators are simply used to show the condition of the line for the time being.

The apparatus provided at one station for one section consists of a plunger key, P, a reversing switch, S W, a small push, V, and the two indicator dials. The indicating pointer for approaching trains is coloured red, that for receding trains is black. The soft-iron needles, *e e*, which are attached to the same axle as the indicating pointers, behind the dials, are polarised by the bar magnet, N S, and play between the pole-pieces of M_1 and M_2. The electromagnets, M_1 and M_2, are shown partly in front view and partly in side view. M_1 actuates the bell hammer, and M_2 actuates the polarised relay tongue, T. The relay, R, is a combined polarised and non-polarised electromagnet, and is also shown partly in front view and partly in side view in order to show the various actions more clearly. All currents passing through the coils of R cause the soft-iron armature, *a*, to be attracted; the tongue, *t*, is only attracted to the stud, W_1, when the current passes in the proper direction. The switch, S W, is a commutator for reversing the line battery. The carbon is attached to the axle which carries the stud shown; the zinc is connected to the bridge, *n*. If the handle of the switch is turned from "off," as shown, to "on," the stud brings the carbon into connection with the "on" line spring, and allows the "off" line spring to make contact with the bridge, *n*, and zinc. The plunger key, P, has three contact points between *l* and *f*, between *l* and *r*, and between the plunger and *g*. When the plunger is at rest *l* is in contact with *r*, and the other contacts are broken. When the plunger is depressed, contact is made between the plunger and *g* and between *l* and *f*, whilst the connection between *l* and *r* is broken. The insulating piece attached to *l* prevents contact between *l* and *g* when the plunger is depressed. The push, V, when depressed makes two contacts—one between *d* and *k*, and the other between *h* and *m*. The two connectors bridging *d* and *k* and *h* and *m* respectively when V is depressed, are fastened together by an insulating piece. The normal position of the switch, S W, is "off," and it is only brought into use for *approaching* trains. Signals originating at the station from which a train is being despatched are given with the switch at "off." The normal position of the indicators is to "Cleared line" when the section is not occupied. When a train is ready to proceed from the "up" station the operations to be gone through are as follows, for block working only:

Up Station.	Down Station.
Depresses P in accordance with code for "Is line clear" signal. Switch at "off."	
	Receives "Is line clear" signal on bell. Switch at "off." Puts switch to "on" and depresses P_1 in accordance with code for "Line is clear" signal.
Receives "Line is clear" signal on bell. Depresses P in accordance with "Line is clear acknowledgment" signal, and at the same time depresses V. "Train going to" indicator put to "On line."	"Train coming from" indicator put to "On line."

On the arrival of the train at the down station:

Up Station.	Down Station.
	Puts switch to "off" and depresses P_1 in accordance with "arrival" signal.
Receives "arrival" signal on bell. Depresses P in accordance with "Arrival acknowledgment" signal, and at the same time depresses V. "Train going to" indicator put to "Cleared line."	"Train coming from" indicator put to "Cleared line."

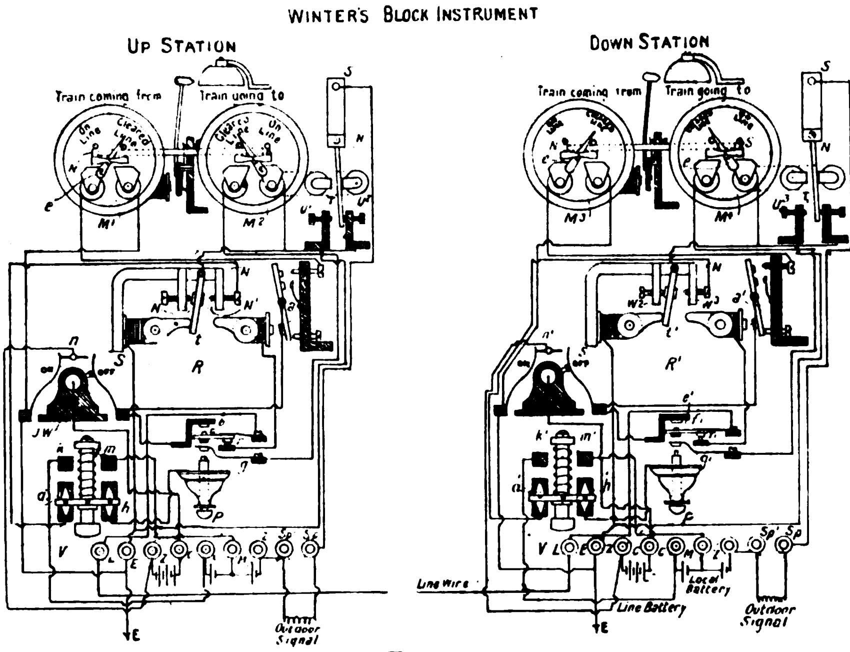

Fig. 51.

The paths of the various currents are as follows:

"Is line clear" signal.

From the line battery, C, through the axle, S W, "off" line spring *f*, *l* to the line L.	From the line L, through *r* and the coils of R_1 to earth.
From earth, through "on" line spring and bridge, *n*, to Z.	a_1 is attracted. Local action, ringing bell (line battery): From C through axle S W_1, "off" line spring M_3, "on" line spring and bridge, *n*, to Z.
	"Line is clear" signal. Switch at "on." From C through axle S W_1 to earth.
From earth, through coils of R, and *r* to line L.	From line L, through l_1, f_1, and "off" line spring to Z.

Digitized by Google

t is moved to W_1, but no current is established owing to the break in local circuit between *d* and *k*.
a is attracted, ringing bell.
Local action (line battery):
From C through axle S W, "off" line spring M_1, "on" line spring and bridge, *n*, to Z.

"Line is clear" acknowledgment.

Line battery.
From C through axle S W, "off" line spring *f*, and *l* to line L.

From line L, through r_1 and coils of R_1 to earth.

From earth, through "on" line spring and bridge, *n*, to Z.

a_1 is attracted.
S W_1 is to "on."

Local battery C M Z.
From C, through K, *d*, W_1, *u*, T, and outdoor semaphore to Z.

From C, through axle S W_1, "on" line spring M_3, "off" line spring and bridge, *n*, to Z.
This puts "Train coming from" indicator to "On line."

Local battery M Z.
From M, through *m*, *h*, P, *g*, M_2, *u*, T, and outdoor semaphore to Z.
This puts "Train going to" indicator to "On line."

Where the outdoor mechanical signal is interlocked with the block instrument, a slight variation in the order of the operations is made. This consists in depressing V alone, at the sending end, after the receipt of the "Line is clear" signal, and before the "Line is clear acknowledgment" signal. This completes the circuit of C M Z alone, and unlocks the mechanical signal. The subsequent depression of V, together with P, for the "Line is clear acknowledgment" signal moves the tongue, T, against u_1, and prevents any current being sent to the outdoor signal locking apparatus until after the "arrival" signal has been received and acknowledged.

When the train, the signalling of which has been traced in the route diagrams, arrives at the down station, the switch, S W_1, is put to "off," and the plunger, P, is depressed in accordance with the "arrival" signal. This signal simply rings the bell at the up station and puts *t* back to W. When the "Arrival acknowledgment" signal is sent in reply from the up station, the currents established by P and V place the indicators at both stations to "Cleared line" and the relay tongue, T, to u_2.

The paths of the currents are easily traced when it is remembered that the switch at the down station has been put to "off." The local current at a_1 (down station) is reversed, and puts the indicator at that place to "Cleared line." The indicator at the up station is placed to "Cleared line" by the action of the battery, C M, the current passing through V.

The interlocking of the starting signal with the block instrument is shown by Figs. 52, 53, and 54. The crank of the lever, L (Fig. 52), is worked by the signal lever in the cabin, but its operation differs from that of most signal levers in that it is not required to hold L up during the time the signal is "off." Fixed to the axle of L, and working with it, is the cam lever, *c*. Immediately above *c*, and in contact with it, is the straight lever, *l*, with its counterweight, *w*. At right angles to *l* is the counterweight, w_1, carried by a crank pivoted at *p*, the short arm, *k*, of which bears against *l* when the latter is horizontal. If the lever L is raised *l* is also raised by the cam, *c*, and *k*, by the falling of w_1, is brought under *l*, and supports it when the lever L has returned to the position shown in Fig. 52. Fig. 53 is drawn to show the positions of the various parts of the apparatus at this stage. So far as the mechanical portion of the apparatus is concerned, the signal arm is free to take up the "off" position, but it is still held up by the electrical interlocking apparatus, which is contained in the box, B, at the top of the post.

The mechanism connected with the electrical interlocking is shown separately in Fig. 54. It consists of the simple electromagnet, R_3, its armature, *i*, and three cranks, one of which carries the hammer, *f*. The axle of the signal arm is shown at *a*. The lever, *b*, and the projection, *m*, work with *a*, and under normal conditions *b* is locked by c_1. Before the releasing current passes through R_3 the lever, *g*, is locked by the armature, but when the armature is attracted *g* is released, and *f* falls upon *e* and releases *b*. If the operation of L, previously described, has been performed before the releasing current passes, or is performed after, the signal arm falls. The projection, *m*, engages with *n*, when the axle, *a*, turns and raises the hammer, *f*, and *g*, engaging with the armature, *i*, locks *f* in the position it previously occupied. When the train passes the signal, the depression of F pulls *k* from under *l*, and the weight, *w*, being free to fall raises the arm to a horizontal position again.

The apparatus is now fully in position for a similar cycle of operations. The signalman, however, is not able to again lower the signal arm until the "arrival" signal has been received and acknowledged for the last train signalled, owing to the tongue, *t*, of the relay, R, being in contact with W_1 (Fig. 51) during the time the "On line" indication is being exhibited.

It will be noticed from the description of the apparatus and the method of working that the principal objects aimed at in the design are concurrent action on the part of the two signalmen concerned before the section can be occupied or the signal lowered for a train to pass forward, and automatic protection of the section occupied by the raising of the signal to danger by the passage of the train over the rail treadle. The apparatus provides, indirectly, by the position of the switch, an indication similar to "Line clear (section ready for train to enter) at the receiving end, but does not provide a similar indication at the sending end.

THE PRINCIPLES OF ALTERNATE-CURRENT WORKING.*

BY ALFRED HAY, B.Sc.(EDIN.), A.I.E.E.

(*Continued from page 208.*)

48. The shape of the E.M.F. curve of an alternator may be determined experimentally by the use of an "instantaneous" contact maker, first introduced by Joubert. The action of this device will be best understood by reference to Fig. 40, which shows the arrangement of apparatus required for determining the shape of the E M.F. curve. T_1 and T_2 are the two terminals of the alternator. E D is an ebonite disc (10in. or 12in. in diameter) which is mounted on the alternator shaft, and which has a thin strip of brass, S, let into its circumference. This strip of brass is connected by means of a wire, W, to an insulated collar, I C,

* Based on a series of evening lectures delivered at the University College, Liverpool.

Digitized by Google

also mounted on the shaft of the alternator. Two brushes, B_1 and B_2, rest, the one on the circumference of the ebonite disc, the other on the insulated collar. The tip of the brush B_1 must be very narrow, so that as the disc, E D, revolves contact is established between B_1 and S once in every revolution for a very short interval of time only. The brush B_1 slides on a graduated scale, G S. By varying the position of the brush B_1 we alter the instant at which contact is made with S. The brush B_1 is in connection with one of the alternator terminals, T_1, while B_2 is connected to one terminal of a condenser, the other terminal of which is connected to the alternator terminal T_2. As the alternator revolves, the condenser is connected, in a certain position of the armature depending on the position of the brush B_1 to the terminals of the alternator. As explained above, this contact is of very short duration. By the rapid succession of these brief contacts the condenser becomes charged to, and is maintained at, a P.D. equal to that between the alternator terminals *at the instant when*

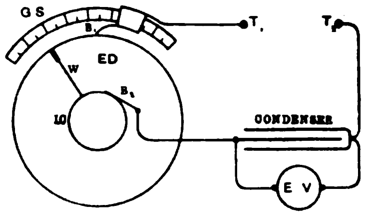

FIG. 40.

contact is made. By determining this P.D. for different positions of the brush B_1 we obtain the shape of the E.M.F. curve, equal displacements of B_1 along its scale corresponding to equal intervals of time.

The P.D. between the condenser terminals may be measured by means of an electrometer or an *electrostatic* voltmeter (E V in Fig. 40). The scale of an electrostatic voltmeter is, however, generally so restricted that it would be difficult to obtain accurate readings over the whole range required. This difficulty may be got over by the ingenious device, due to Dr. Fleming, of using an auxiliary E.M.F. in the electrometer circuit. Thus, let us suppose that when the brush B_1 is in a certain position the corresponding P.D. is too small to be read on the electrostatic voltmeter. We have merely to connect (Fig. 41) a certain number of cells (secondary cells are very convenient for this purpose) in series with the voltmeter, and so as to increase the deflection until it can be read accurately on the voltmeter scale. By subtracting from this reading the E.M.F. of the cells, we obtain the P.D. at the condenser terminals. The same method may be used for reducing the voltmeter reading should the latter prove too high. In this case the cells are connected so that their E.M.F. opposes the P.D. at the condenser terminals, and this P.D. is obtained by *adding* the E.M.F. of the cells to the voltmeter reading.

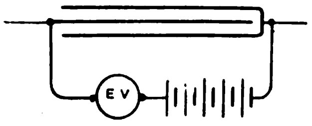

FIG. 41.

Since an electrostatic instrument is used, it might be thought that the condenser is unnecessary. This would be the case if the insulation of the voltmeter were perfect Owing, however, to the leakage which takes place, it is desirable to give the instrument a large capacity, and this is accomplished by connecting a condenser across its terminals. Even then a certain appreciable amount of leakage may take place, and this will depend on the interval which elapses between two consecutive contacts—*i.e.*, on the speed of the alternator. It is, therefore, always best to calibrate the combination of electrostatic voltmeter and condenser for the particular speed used by applying a known *steady* P.D. to the points T_1 and T_2 of the circuit (Fig. 40), and noting the corresponding reading of the electrostatic voltmeter. If the insulation of the condenser is very high, it will probably be found that there is no appreciable difference between the two readings obtained when the contact is stationary and running respectively. But with a slightly leaky condenser such a difference might exist, and a comparison of the two readings supplies a correcting factor, by which the readings of the electrostatic voltmeter must be multiplied, in order to give the correct values of the instantaneous P.D.

49. The method just explained for determining the shape of the E M.F. wave may also be used for the determination of the *current* wave in an inductive circuit. Fig. 42 shows the arrangement of connections required for this purpose. I R is the inductive circuit in which the current-wave is to be determined; N R is a small non-inductive resistance connected in series with the inductive resistance. The readings obtained with the brush B_1 placed in different positions give us the corresponding instantaneous P.D.'s at the terminals of the non-inductive resistance. Now, since a non-inductive resistance is incapable of offering a counter E.M.F. to a varying current it follows that at every instant the current through such a resistance is simply equal to

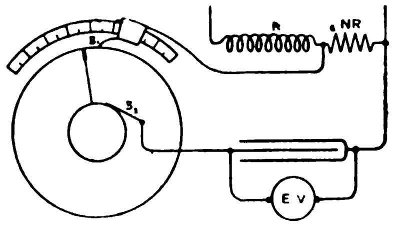

FIG. 42.

the quotient of the P.D. by the resistance. Hence, by dividing the values of the instantaneous P.D. by the resistance we obtain the corresponding values of the current.

In order that the introduction of the non-inductive resistance may not affect the existing conditions of the circuit to any great extent, it is desirable to make this resistance as small as possible. The P.D.'s, however, which will have to be measured in that case will also be small, and an electrostatic voltmeter would not be suitable for this purpose. The best instrument in this case would be an electrometer used heterostatically—*i.e.*, with its needle charged to a high potential and insulated from the quadrants. *Good* electrometers, however, are very expensive instruments, and are not available in every laboratory. A good substitute for an electrometer is provided by the combination of a slide-wire with a galvanometer and an auxiliary source of E.M.F. The arrangement of connections is shown in Fig. 43, where A B represents the slide-wire along which

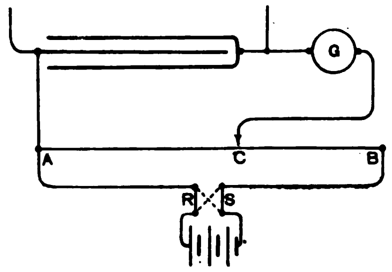

FIG. 43.

passes a steady current supplied by some constant source of E.M.F. (such as a secondary cell). A reversing switch, R S, is included in this circuit. The point A, being permanently connected to one terminal of the condenser, is maintained at the same potential as that terminal. When the sliding contact of the bridge wire is momentarily depressed at C, it connects the point C to the other terminal of the condenser through the galvanometer, G. If these two points happen to be at the same potential, no current will pass through the galvanometer. The position of C is adjusted until the galanometer fails to show any deflection. It is obvious that under these conditions the P.D. at the condenser terminals is proportional to the length A C, which is read off on the slide-wire scale.* In order to determine the constant which will convert the

* On the supposition that the resistance of the wire per unit of length is uniform. If this is not the case, the wire must be specially calibrated.

Digitized by Google

scale readings into amperes, a *known* steady current is passed through the non-inductive resistance, N R, the instantaneous contact-maker running at the speed at which it is to be used, and the corresponding scale reading is noted.

By taking corresponding sets of readings for the P.D. and current in any inductive part of a circuit, and plotting the results obtained on a sheet of squared paper, we not only determine the shape of the P.D. and current waves, but also their phase relation, a knowledge of which is frequently of great importance.

Various modifications of the methods just described for determining the wave-shape have been used by different experimenters, and some important improvements have been introduced into these methods recently. The determination of the wave-shape by the methods given above is a somewhat tedious process, on account of the comparatively long time required to obtain a set of readings. By means of suitably-designed apparatus the wave-shape may be obtained much more quickly.

In some cases it may be necessary to determine the wave-shape when the alternator is not accessible. A special form of apparatus for this purpose has been designed by Dr. Fleming, and another form by Dr. Hicks. In both cases a *synchronous* alternating-current motor is used for driving the instantaneous contact-maker. By a *synchronous* motor is meant one whose speed bears a definite ratio to the periodicity of the alternating current.

(To be continued.)

ON THE MEASUREMENT OF THE INSULATION RESISTANCE OF CONTINUOUS-CURRENT THREE-WIRE SYSTEMS WHILE AT WORK.

BY EDWIN J. HOUSTON, PH.D., AND A. E. KENNELLY, SC.D.

A three-wire system for incandescent lighting may be—

(*a*) Contained within the walls of a single building and have an insulation from ground of hundreds or thousands of ohms.

(*b*) It may extend over a large network of buried conductors in streets, and have an insulation so low as to be measurable in ohms, or decimals of an ohm.

(*c*) It may be grounded permanently at its neutral, in which case the insulation is, of course, nil.

It is here proposed to consider systems corresponding to classes (*a*) and (*b*), which may be considered as insulated systems, in contradistinction to systems of class (*c*), which are uninsulated systems.

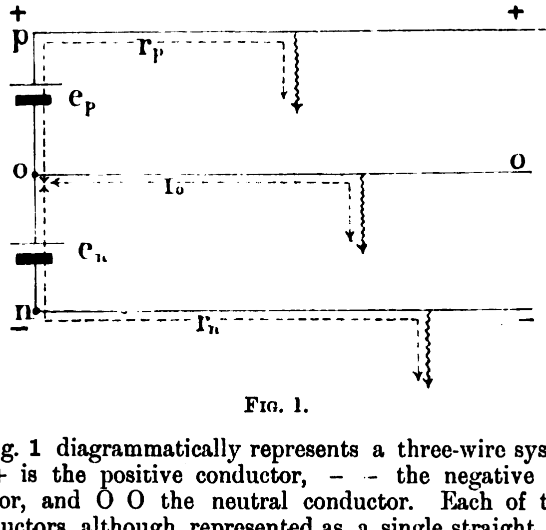

FIG. 1.

Fig. 1 diagrammatically represents a three-wire system. + + is the positive conductor, – – the negative conductor, and O O the neutral conductor. Each of these conductors, although represented as a single straight line, may be considered as spreading, branching out, and ramifying over a network of any degree of complexity. These feeders or mains are supplied by two E.M.F.'s of e_p volts on the positive side, and e_n volts on the negative side respectively, their sum $e_p + e_n$ being E volts. Each of the three conductors has electric leakage distributed along it in any manner. Between them are connected lamps or other translating devices. Under these conditions, the conductors will behave as though they possessed single resultant leaks of r_p, r_o, and r_n ohms respectively, including the conductor resistances up to the resultants, and measured from the neutral bus bar, *o*, or common connection, r_p and r_n therefore include the small resistances in the generator armatures. It may be considered that for all practical purposes these apparent insulation resistances do not depend upon the load on the system, or, in other words, that the drop of pressure in the conductors when loaded is relatively too small to affect the apparent resistances up to and included in the resultant faults. On this assumption we may safely ignore the load on the system, and consider the system as completely unloaded, and as represented in Fig. 1, where the only currents which flow are leakage currents.

Let the potentials between the points *p*, *o*, and *n* and the ground be measured and denoted by u_p, u_o, and u_n respectively. If the insulation of the system were perfect, and each of the two E.M.F.'s, e_p and e_n, equal, the potential at *o* would be zero, while those at *p* and *n* would be $+e_p$ and $-e_n$ volts respectively. The slightest dissymmetrical leakage in the system would, however, change this distribution; such, for example, as the connection of a grounded voltmeter to either *p* or *n*. In almost all practical cases, however, the influence of the leakage effected through the resistance of a high-resistance voltmeter is negligible, and the potentials at *p*, *o*, and *n* are:

$$u_p = \frac{g_o e_p + g_n E}{G} \text{ volts} \quad . \quad . \quad . \quad . \quad . \quad (1)$$

$$u_o = u_p - e_p = \frac{g_n e_n - g_p e_p}{G} \text{ volts} \quad . \quad . \quad (2)$$

$$u_n = u_p - e_p - e_n = u_o - e_n = -\frac{g_o e_n + g_p E}{G} \text{ volts} \quad (3)$$

where g_p, g_o, and $g_n = \frac{1}{r_p}\ \frac{1}{r_o}$ and $\frac{1}{r_n}$ mhos respectively (4)

also $\quad G = g_p + g_o + g_n$ mhos . . . . (5)

$$E = e_p + e_n \text{ volts.}$$

For example, if $r_p = 100$ ohms, $g_p = \frac{1}{100} = 0{\cdot}010$ mho

$r_o = 200$ ohms, $g_o = \frac{1}{200} = 0{\cdot}005$ mho

$r_n = 250$ ohms, $g_n = \frac{1}{250} = 0{\cdot}004$ mho

G $= 0{\cdot}019$ mho

Also if $e_p = 120$ volts

$e_n = 120$ volts

$$u_p = \frac{0{\cdot}005 \times 120 + 0{\cdot}004(120+120)}{0{\cdot}019} = 82{\cdot}12 \text{ volts}$$

$$u_o = \frac{0{\cdot}004 \times 120 - 0{\cdot}01 \times 120}{0{\cdot}019} = -37{\cdot}88 \text{ volts}$$

$$u_n = -\frac{0{\cdot}005 \times 120 + 0{\cdot}01\ (120+120)}{0{\cdot}019} = -157{\cdot}88 \text{ volts.}$$

Theoretically, it is evidently only necessary to observe one potential, since the difference between any pair of the potentials is the E.M.F. between them as supplied at the generator terminals.

It is evident that when a ground occurs on one conductor, its potential becomes zero. If a ground occurs on the positive conductor, there is a tendency to the condition

$$u_p = o\,;\ u_o = -e_p\,;\ u_n = -E.$$

If a ground occurs on the negative conductor, the tendency is to be the condition

$$u_p = E\,;\ u_o = e_n\,;\ u_n = o\,;$$

and if the ground occurs on the neutral main, the corresponding condition is

$$u_p = e_p\,;\ u_o = o\,;\ u_n = -e_n.$$

Consequently, a high reading on an outside conductor indicates a ground on the opposite outside conductor, while equal and opposite potentials on the outside conductors

Digitized by Google

indicate symmetrical leakage—that is to say, leakage which may be either great or small, but is either on the neutral conductor or symmetrically distributed with regard to it.

While, therefore, a voltmeter connected to one of the outside conductors of a three-wire system gives qualitative information concerning the insulation of the system, it gives but little quantitative information.

We propose to show how such quantitative information may be obtained. So far as the authors are aware, no method has been published for the determination of the three insulation resistances, r_p, r_o, and r_n, during the working of the system, without the use of a Wheatstone bridge of special construction.

The first step is to find G, the joint insulation conductance of the system, by a method already known. For this purpose a leak of g mhos is connected to one of the bus bars at the central station, say at O, Fig. 1. Then u_o falls to $u_o{}^1 = \frac{g_n e_n - g_p e_p}{G + g}$ volts (6). That is to say, the potential of the neutral bus bar is lowered in the ratio $\frac{G}{G+g}$. The same is true if this single link be applied successively at p and at n when

$$u_p{}' = \frac{g_o e_p + g_n E}{G + g}; \text{ and } u_n{}^1 = -\frac{g_o e_n + g_p E}{G + g} \text{ volts} \quad . \quad (7)$$

successfully and respectively. In other words, the leak, g, lowers the potential of the bus to which it is connected in the ratio of $\frac{G}{G+g}$. If $g = G$, this ratio will be one-half, so that if a leak be applied to one of the bus bars, and adjusted so that the potential of the bus is thereby halved, the conductance of the leak is equal to the insulation conductance of the entire system, including all three conductors. If the leak, g, cannot be so adjusted, we have the relation :

$$G = g\left(\frac{u'}{u - u'}\right) \text{ mhos} \quad . \quad . \quad . \quad . \quad (8)$$

This result, or its equivalent, was first pointed out by Dr. O. Frölich in the *Elektrotechnische Zeitschrift*, January, 1893.

For example, in the case last considered, suppose a conductance of $g = 0{\cdot}025$ mho (40 ohms) connected to the neutral bus bar, then by (6)

$$u_o{}^1 = \frac{0{\cdot}004 \times 120 - 0{\cdot}01 \times 120}{0{\cdot}019 + 0{\cdot}025} = -\frac{0{\cdot}72}{0{\cdot}044} = -16{\cdot}36 \text{ volts,}$$

and by (8) $G = 0{\cdot}025\left(\frac{-16{\cdot}36}{-37{\cdot}88 + 16{\cdot}36}\right)$

$$= 0{\cdot}025 \times \frac{-16{\cdot}36}{21{\cdot}52} = 0{\cdot}019 \text{ mho,}$$

so that the resultant fault, $\frac{1}{G}$, in the system has a resistance of $\frac{1}{0{\cdot}019}$, or 52·6 ohms. This test, therefore, determines $G = g_p + g_o + g_n$. If e_p and e_n are made equal for the purposes of a brief test, we obtain one other relation between the required quantities g_p, g_o, and g_n — namely, when $e_p = e_n$,

$$g_n - g_p = \frac{G}{E}(u_p + u_n) \text{ mhos.} \quad . \quad . \quad (9)$$

Thus, in the preceding example, since we have already assumed $e_p = e_n$,

$$g_n - g_p = \frac{0{\cdot}019}{240}(82{\cdot}12 - 157{\cdot}88),$$

$$= \frac{0{\cdot}019 \times -75{\cdot}76}{240} = -0{\cdot}006 \text{ mho.}$$

$$\therefore g_p - g_n = 0{\cdot}006 \text{ mho.}$$

It would appear that no combination of leaks applied to the system suffices to supply another independent relation between g_p, g_o, and g_n, so that while equation (8) gives the aggregate or joint leakage conductance of the system, one more independent equation is needed besides (9) to determine the separate conductances g_p, g_o, and g_n, unless one of them is very great—*i.e.*, unless one conductor is grounded.

Referring, however, to equation (1) we find that if we alter the E.M.F. e_n by an amount Δe_n, we produce an alteration in u_p of

$$\Delta u_p = \frac{g_n \Delta e_n}{G} \quad . \quad . \quad . \quad . \quad (10)$$

so that $g_n = \frac{G \, \Delta u_p}{\Delta e_n}$ mhos . . . (11)

Similarly, in equation (3) a change of e_p produces a change in u_n of $\Delta u_n = -\frac{g_p, \Delta e_p}{G}$ . . . . (12)

from which $g_p = -\frac{G \, \Delta u_n}{\Delta e_p}$ mhos . . . (13)

Consequently, to make this test we introduce suddenly as large a variation in e_p, and then in e_n, as the system will permit. The corresponding changes in u_n and u_p are noted. From these g_n and g_p may be computed as above.

Thus, in the case considered, let e_p be suddenly increased from 117 to 123 volts, e_n remaining at 120. The potential at the opposite side of the system would correspondingly fall from $u_n = -156{\cdot}32$ volts to $u_n = -159{\cdot}48$ volts. Again, let e_n be suddenly increased from 117 to 123 volts, e_p remaining at 120. The potential at the opposite side of the system would correspondingly rise from $u_p = 81{\cdot}47$ volts to 82·73 volts :

By (11) $g_n = 0{\cdot}019 \times \frac{1{\cdot}26}{6} = 0{\cdot}004$ mho, $\therefore r_n = 250$ ohms.

By (13) $g_p = -0{\cdot}019 \times \frac{-3{\cdot}16}{6} = 0{\cdot}010$ mho, $r_p = 100$ ohms.

Equation (9) supplies a check to these two values. Finally, $g_o = G - (g_n + g_p) = 0{\cdot}019 - 0{\cdot}014 = 0{\cdot}005$ mho, $\therefore r_o = 200$ ohms. Consequently, when a change in the E.M.F. on one side of the system produces very little change in the opposite potential, the leakage on that side is small compared with the total leakage of the system, and *per contra*.

The measurement is best conducted with the aid of storage batteries ; otherwise, the variations ordinarily occurring in the pressures between bus bars may mask the changes effected as described. If the test is conducted during the daytime, the temporary disturbances of pressure it produced over the system will not be so objectionable.

As another example of the application of the method, suppose a three-wire system and the following observations made at the central station :

$e_p = 120$; $e_n = 120$; $u_n = -91\frac{3}{4}$ volts.

A leak of 10 ohms, $g = 0{\cdot}1$ applied at n changed u_n to $-74\frac{1}{3}$.

$e_p = 120$; $e_n = 117$ changed to 123, u_p changed from -91 to $-92{\cdot}5$.

$e_n = 120$; $e_p = 117$ changed to 123, u_n changed fron $146\frac{3}{4}$ to $149\frac{1}{2}$.

Required the insulation resistance of the three main conductors.

Here by (8)

$$G = 0{\cdot}1\left(\frac{-74{\cdot}33}{-91{\cdot}75 + 74{\cdot}33}\right) = 0{\cdot}427 \text{ mho} = 2{\cdot}34 \text{ ohms.}$$

By (11) $g_n = 0{\cdot}427 \times \frac{2{\cdot}75}{6} = 0{\cdot}196$ mho = 5·10 ohms.

By (13) $g_p = -0{\cdot}427 \times \frac{-1{\cdot}5}{6} = 0{\cdot}107$ = ·35 ohm.

0·303 0·303

$g_o =$ 0·124 = 8·06 ohms.

In cases where one conductor is grounded through a small resistance, the leakage conductance of that conductor, and therefore of the system, becomes so large that the method fails. It is always possible, however, to measure the resistance of the leak in the grounded conductor, including the resistance of the conductor up to the ground,

Digitized by Google

Thus, in Fig. 2, let G be the ground on the neutral conductor, through a small resistance, r_0; A is an ammeter, and r a suitable resistance of German silver or other alloy of constant resistance; S is a ground-switch for making good

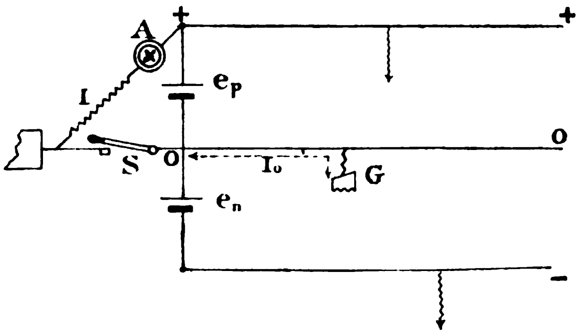

FIG. 2.

connection between ground and the neutral bus. Then the current, i, through the ammeter will be with switch open:

$$i = \frac{e_p}{r + r_0} \text{ amperes} \quad . \quad . \quad . \quad . \quad (14)$$

with the switch closed

$$i^1 = \frac{e_p}{r} \text{ amperes} \quad . \quad . \quad . \quad . \quad (15)$$

$$\therefore r_0 = r\left(\frac{i - i^1}{i}\right) = \frac{e_p}{i^1}\left(\frac{i - i^1}{i}\right) \text{ ohms} \quad . \quad . \quad (16)$$

or,

$$g_0 = g\frac{i}{i - i^1} = \frac{i^1}{e_p}\left(\frac{i}{i - i^1}\right) \text{ mhos} \quad . \quad . \quad (17)$$

Thus, a three-wire system with uninsulated or imperfectly grounded neutral and E.M.F. e_p – 120 volts gave 11·43 amperes with the neutral ground-switch open, and 12 amperes with the switch closed, the resistance, r, being 10 ohms ($g = 0{\cdot}1$).

By (17) $g_0 = \frac{0{\cdot}1 \times 11{\cdot}43}{12 - 11{\cdot}43} = \frac{1{\cdot}143}{0{\cdot}57} = 2$ mhos.

$$r_0 = \tfrac{1}{2} \text{ ohm.}$$

RÉSUMÉ.

The means of determining the joint leakage conductance of a three-wire system are already known, but no means appear to be known for determining the individual leakage conductances of the three separate conductors under load, except by the use of the Wheatstone bridge. It is here shown (1) how the individual leakage conductances may be approximately determined by varying the working pressure on one side of the system, and observing the corresponding variation of potential to ground on the other; (2) how the resistance in and up to the ground of a grounded conductor under load may be measured from the central station.—*The Electrical World.*

THE "VANBE" ARC LAMP.

We were invited on Monday last to inspect this arc lamp, which is being manufactured by Messrs. Vaughan and Brown, of Kirby-street, E.C. We understand that this lamp has found favour with the officials at Woolwich Arsenal, where about 200 of these lamps are now in use. The success of the lamp, after an extended trial at the arsenal, and in other installations erected by Messrs. Vaughan and Brown, has led the firm to put the lamp on the market. The general arrangement of the mechanism can be seen in Fig. 1. The feeding gear has a positive drive, actuated by an oscillating armature, A. This armature is acted on by the two magnet cores energised by the shunt coils, S S. The resistance of these shunt coils is about 500 ohms. When the armature is drawn towards the core the circuit is broken at the contact breaker, F. In fact, these parts act in the same way as the mechanism in a trembling bell. The armature is attached to the brass lever, B, at the upper end of which is hinged the pawl gearing in the ratchet wheel, R. A spring also attached to the end of this lever keeps the armature away from the magnets normally. The forward motion is given to the ratchet wheel by the tension in the spring after the contact has been broken. The backward motion of the pawl is caused by the magnetic attraction. The shaft on which the ratchet wheel is geared has a thread cut on it, W, which gears in a worm-wheel. Fastened to the worm-wheel is the wheel C, round which passes the chain. One end of the chain is attached to each carbon-holder, so that the lamp is approximately a focussing one. The upper carbon descends as the lower carbon ascends and by an equal amount. So if the diameters of the two carbons are correctly chosen so that equal lengths are consumed of each, the position of the arc in the globe does not vary. The feeding of the lamp is thus effected by the shunt coils, and the individual impulses moving the carbons together are exceedingly small. When adjusted, the lamp feeds one tooth of the ratchet wheel at a time, and this with the worm gear used is equivalent to shortening the arc about $\frac{1}{300}$in. No dash-pot is required with this feed, as on account of the nature of the driving gear no sudden change can occur.

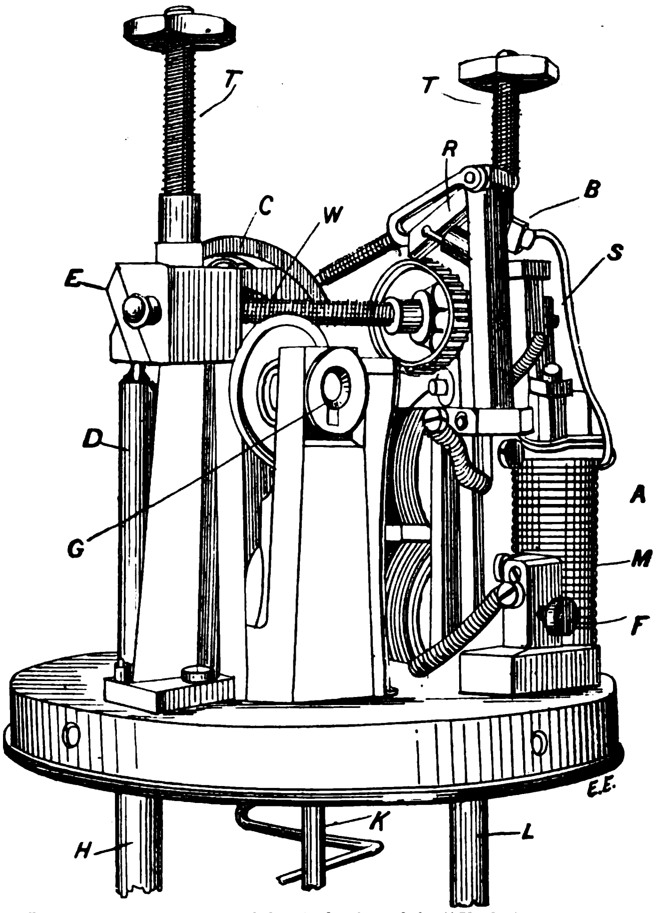

FIG. 1.—Prospective View of the Mechanism of the "Vanbe" Arc Lamp.

The next point to be considered is the striking of the arc when the shunt coils cause the carbons to touch. To separate the carbons the worm-shaft is arranged to have two motions. The first is the rotating motion giving the feed, and the second a horizontal movement to strike the arc. At one end of the shaft a horseshoe electromagnet is placed, wound with thick wire, M, in series with the arc. The armature of this magnet when attracted to the cores presses on the end of the worm-shaft, causing it to move a predetermined amount. The threads on the shaft, gearing with the worm-wheel then act as a rack and cause the wheel to revolve, separating the carbons. In the new position thus taken up by the shaft the feeding gear acts as before. Having described the main principles of the lamp, the individual details deserve special attention. It is to these details, and to the workmanship of the whole, that the success of any arc lamp is due. Although anyone with the smallest experience can design a lamp to give comparatively satisfactory results in the laboratory, very few of the new lamps brought out can stand a test after two years' working outdoors. In the lamp before us great attention

Digitized by Google

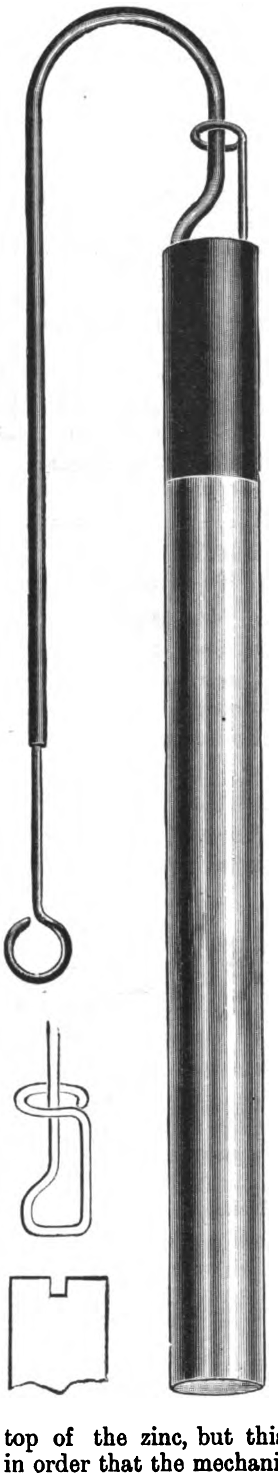
has been paid to the design of details. For instance, the worm-shaft is supported at either end on ball bearings, which are arranged so as to be easily adjusted in the first instance. Besides securing perfect alignment and little friction in working, this arrangement enables the worm to be placed exactly in pitch to the wheel. The chain which gears in the wheel, C, is made of steel, and great care has been exercised to ensure uniformity in the dimensions of the several links. The chain is brass-plated, to guard against rust, and gears in the wheel without slip. In order to prevent this chain from leaving the wheel it is passed through a guide, D, on its way down to the rod, H. A guard, concentric with the chain wheel, C, is placed at such a distance from the wheel that the chain cannot slip out even when slack. In moving the carbon-holders apart for retrimming, a ratchet on one side of the chain wheel gives the necessary release from the worm-wheel. A convenient arrangement in connection with the pawl of the ratchet allows the chain wheel to revolve in either direction with freedom when required. The arrangement of carbon-holder supports is not unlike many others on the market except in detail. The upper carbon-holder frame embraces one rod and rests against the other. In the embracing brush, roller bearings are provided to diminish friction. The lower carbon-holder frame on one side passes up the inside of the tube, H, the other end of the frame resting on the opposite rod. Down this latter rod is passed the insulated wire conveying the current to the lower holder. Porcelain insulation is used for this holder and for the contact breaker, F. The carbon-holders are arranged with spring grips and ball centreing gear. The terminals, T T, can be seen at the top of the lamp. These project through the cover, and the under nut is used as a means of fastening the case on to the main frame.

FIG. 2.—General View of the "Vaube" Arc Lamp.

The parts of the lamp are all made to gauge so as to be readily interchangeable. The cases for indoor and outdoor work have been designed with care, and the globe-lowering arrangement seen in Fig. 2 is very neat. The only trouble we find likely to occur is due to the want of recuperative power after a mushroom has temporarily short-circuited the carbon. The series coil is then powerless to lengthen the arc. Using good carbons, and with careful adjustment, this can be avoided. We are informed that a number of these lamps has also been supplied to the General Post Office, and that at the Woolwich Arsenal as many as 12 lamps are being run in series. The lamps for use in this circuit are provided with a cut-out and equivalent resistance. The resistance wire is wound on fireproof insulation round the outside of the cast.

The cut-out is compound wound, and protects the lamps when first switched in. As they do not all have the same distance to feed, the voltage on the lamp in which the carbons touches last rises. Thus, if all the lamps but one have feed down, this voltage across the shunt coils of the last lamp would be practically the full voltage of the circuit. Instead of this dangerous condition, the cut-out goes and inserts a resistance equivalent to the impedance of the lamp in the circuit. The main current is thus established, and the lamp, although cut-out, continues to feed till the carbons touch. This short-circuits the resistance and releases the cut-out. Thus the cut-out automatically cuts in, and is in this respect a most valuable adjunct to the lamp.

THE PARSONS IMPROVED LECLANCHE BATTERY ZINCS.



One weak point in ordinary Leclanché cells is the liability of the zinc terminal wire to break off short where it joins the zinc rod. This has been due to two causes—*i.e.*, chemical action and mechanical strains. Several methods for overcoming this weakness have been tried, the most noteworthy being the fixing of guttapercha and other flexible cements round the top of zincs where the terminal wire leaves. This prevents the chemical action to a large extent by keeping the junction dry, but does not protect against bending strains.

We illustrate herewith a new and simple method of protection against this last effect. A glance at the woodcuts will explain the principle on which what the makers call the unbreakable terminal zinc rods are made. The rod is slotted in the usual way. The terminal wire is then bent into the form illustrated in outline, and firmly soldered into the slot, the other end of terminal wire being bent into a loop in the usual way. The safety ring prevents the wire making the sudden bend which so soon results in breakage. It is only necessary to take a sample rod and bend the wire backwards and forwards, counting the number of bends before breakage occurs to prove the utility of the invention.

Messrs. Gent and Co., of Leicester, own the patent rights for this simple invention, and are the sole makers, and they stock the rods in six different sizes. We understand that protective compounds are used round the top of the zinc, but this is not shown in the illustration in order that the mechanical construction can be seen.
